TABLE OF CONTENTS

	Page	Russ. Page
1. Investigation of the Adsorption of Vapors on Quartz. Communication 1 Method of Investigating Adsorption Isotherms. A.I. Sarakhov	3	5
2. Effect of the Temperature Factor on the Rate of Corrosion of Metals in Electrolytes. V. V. Gerasimov, G. V. Akimov and I. L. Rozenfeld	9	12
3. Derivatives of Unsaturated Phosphonic Acids. Communication 16. Diesters of 2-Indenylphosphonic Acid. K. N. Anisimov and A. N. Nesmeyanov	13	16
4. Derivatives of Unsaturated Phosphonic Acids. Communication 17. Derivatives of Styrylphosphonic Acid. K. N. Anisimov and A. N. Nesmeyanov	17	19
5. Derivatives of Unsaturated Phosphonic Acids. Communication 18. 2-(Alkylthio) Vinylphosphonic Dichlorides and Their Derivatives. K. N. Anisimov, N. E. Kolobova and A. N. Nesmeyanov	21	23
6. Reactions of Organomercury Bases With Unsaturated Compounds. I. F. Lutsenko and E. I. Yurkova	25	27
7. Synthesis of Polycyclic Compounds Related to Steroids. Communication 36. Condensation of Cyclic Saturated Ketones with α,β-Unsaturated Cyclic Ketones. I. N. Nazarov, S. I. Zavyalov and M. S. Burmistrova	31	32
8. Hydrogenation of Isopropenylcyclopropane in Presence of Palladium Black. B. A. Kazansky, M. Yu. Lukina, A. I. Malyshev, V. T. Aleksanyan and Kh. E. Sterin	35	36
9. High-Temperature Reactions of Propyl- and Isopropyl-Benzenes Over a Nickel-Alumina Catalyst in Presence of Hydrogen at High Pressure. N. I. Shuikin, N. G. Berdnikova and Yu. P. Egorov	43	43
10. Reactivity and Molecular Optical Properties of Alkenylsilanes. A. D. Petrov, Yu. P. Egorov, V. F. Mironov, G. I. Nikishin and A. A. Bugorkova	49	50
11. Homogeneous Destructive Hydrogenation of Isopropylbenzene Under High Pressures of Hydrogen. M. G. Gonikberg and V. E. Nikitenkov	55	56
12. Low Temperature Alkylation of α- and β-Olefins with Tertiary Alkyl Halides in Presence of Zinc Chloride. A. P. Mescheryakov, E. I. Erzyutova and A. D. Petrov	65	67
13. Polyorganoaluminosiloxanes. K. A. Andrianov and T. N. Ganina	71	74
14. Polymerization and Copolymerization of N-Vinyl Compounds. Communication 1. Copolymerization of 9-Vinylcarbazole with Vinyl Esters. S. N. Ushakov and A. F. Nikolaev	79	83
15. Hydrogen Bonding in ε-Caprolactam and Polycaprolactam. V. N. Nikitin	87	92
16. Macromolecular Compounds. Communication 87. Mixed Polyamides Containing Certain Amino-Acid Residues. V. V. Korshak and T. M. Frunze	93	98

TABLE OF CONTENTS (continued)

	Page	Russ. Page
17. Macromolecular Compounds, Communication 88. Polyamides Containing Ether Linkages in their Macromolecular Chains, V. V. Korshak and G. N. Chelnokova	97	103
18. Macromolecular Compounds, Communication 89. Three-Component Mixed Polyamide Systems Having Amino-Acid Components, V. V. Korshak, T. M. Frunze and T. A. Dikareva	101	108
19. Macromolecular Compounds, Communication 90. Polycondensation of 1,2-Dichloroethane With Tetralin, G. S. Kolesnikov, V. V. Korshak, M. A. Andreeva and A. I. Kitaigorodsky	107	114
20. Infrared Absorption Spectra of Some Bases of the Pyridine Series, D. N. Shigorin, Ya. L. Danyushevsky and Ya. L. Goldfarb	113	120
Brief Communications		
21. Dipole Moments of Derivatives of 1,3,5-Trinitrobenzene, E. A. Shott-Lvova and Ya. K. Syrkin	119	127
22. Selective Action of Catalysts Prepared from Nickelous Oxide Treated with Steam Under Pressure, L. Kh. Freidlin, A. A. Balandin and N. V. Borunova	121	128
23. Oxidation Potentials of Organic Sulfur Compounds, V. G. Lukyanitsa and G. D. Galpern	125	130
Current Events		
24. Third All-Union Conference on Physicochemical Analysis	127	132

Bulletin of the Academy of Sciences of the U.S.S.R.

Division of Chemical Sciences

February, 1956

TABLE OF CONTENTS

	Page	Russ. Page
1. Unusual Valencies of Some Metals. B. V. Nekrasov	131	137
2. Possible Mechanism of the Catalytic Oxidation of Hydrogen on Metals. O. V. Krylov and S. Z. Roginsky	139	145
3. Investigation of the Adsorption of Vapors on Quartz. Communication 2. Adsorption Isotherms of Various Vapors. A. I. Sarakhov	145	150
4. Liquation in the System ZrO_2 - SiO_2. N. A. Toropov and F. Ya. Galakhov	153	158
5. Exchange Reactions of Stereoisomeric Mercury Derivatives of Stilbene. A. N. Nesmeyanov, A. E. Borisov and N. A. Volkenau	157	162
6. 2-Aminovinyl Ketones. Communication 4. Synthesis of Ketones of the Pyridine Series. N. K. Kochetkov, Yanush Dombrovsky, A. V. Bazhenova, E. S. Severin and A. N. Nesmeyanov	165	172
7. Separation of Amino Carboxylic Acids from Ammonium Chloride with the Aid of Cation-Exchange Resins. E. I. Vasilyeva and R. Kh. Freidlina	169	177
8. Addition of Mercury Salts to Vinyl Ethers. Preparation of Mercurated Acylals. I. F. Lutsenko, R. M. Khomutov and L. V. Eliseeva	173	181
9. Properties and Reactions of Alkyl and Aryl Propylene Phosphites. Communication 1. Addition Reactions. A. E. Arbuzov and N. A. Razumova	179	187
10. O,O- and O,S-Dialkyl Alkylphosphonothioates. M. I. Kabachnik, T. A. Mastryukova and N. I. Kurochkin	185	193
11. Acetylene Derivatives. Communication 173. Cyanoethylation of Acetylenic Alcohols. I. N. Nazarov and G. A. Shvekhgeimer	191	199
12. Effect of Enolization on the Ability of β-Dicarbonyl Compounds to Undergo Michael and C-Alkylation Reactions. I. N. Nazarov, S. I. Zavyalov and M. S. Burmistrova	197	205
13. Possibility of Forming Cyclopentadiene from Heterocyclic Compounds Containing Five Carbon Atoms. N. I. Shuikin and V. A. Tulupov	205	213
14. Contact-Catalysis Refining of Tuimazin Gasoline. N. I. Shuikin and E. D. Tulupova	211	220
15. Polymerization and Copolymerization of N-Vinyl Compounds. Communication 2. Some Characteristics of the Copolymerization of Vinyl Acetate with 9-Vinylcarbazole and the Properties of the Copolymers. S. N. Ushakov and A. F. Nikolaev	217	226
16. Macromolecular Compounds. Communication 91. Transarylation of Bibenzyl at Various Temperatures. G. S. Kolesnikov and V. V. Korshak	223	232
17. Macromolecular Compounds. Communication 92. Effect of Catalyst Concentration on the Transarylation of Bibenzyl. G. S. Kolesnikov and V. V. Korshak	229	239

TABLE OF CONTENTS (continued)

	Page	Russ. Page
18. Synthesis and Reactions of Chloro(2-Methylallyl)Silanes. A. D. Petrov and G. I. Nikishin	233	243
19. Action of Dilute Nitric Acid on Isolated Lignin. A. A. Chulkanova, L. L. Sergeeva and N. N. Shorygina	239	250
Brief Communications		
20. Condensation of Ferrocene with Aldehydes. A. N. Nesmeyanov and I. I. Kritskaya	243	253
21. Dipole Moments of Alkyl 2-Dialkylaminovinyl Ketones. A. N. Shidlovskaya, Ya. K. Syrkin and N. K. Kochetkov	245	254
22. Cyanoethylation of Trichlorosilane. A. D. Petrov, V. F. Mironov, V. M. Vdovin and S. I. Sadykh-Zade	247	256
23. Destructive Hydrogenation of 2-Methylthiophene with Hydrogen at High Pressure. M. G. Gonikberg, V. V. Kiseleva and Ya. L. Goldfarb	249	257
Current Events		
24. Conference on Electrochemistry at the Polish Academy of Sciences. Prof. A. T. Vagramyan	253	260

Bulletin of the Academy of Sciences of the U.S.S.R.

March, 1956

TABLE OF CONTENTS

	Page	Russ. Page
1. In Furtherance of Continuing Progress in the Science of Chemistry	257	265
2. Thermodynamical Investigations of Wetting Phenomena. A. V. Dumansky	261	270
3. Specificity of the Catalytic Oxidation of Unsaturated Hydrocarbons. L. Ya. Margolis and S. Z. Roginsky	271	281
4. Structure of Sodium Borosilicate Glasses in its Relation to The Phenomenon of Opalescence. Communication 4. Dependence of the Structure of Sodium Borosilicate Glasses on the Duration of Heating at Constant Temperature. E. A. Porai-Koshits, D. I. Levin and N. S. Andreev	277	287
5. Systems Containing Hydrogen Peroxide at High Concentration. Communication 11. Characterization of the Solid Phases of the System $LiOH-H_2O_2-H_2O$ by Thermal Analysis. S. Z. Makarov and T. A. Dobrynina	283	294
6. Physicochemical Study of the System Sodium Superoxide-Sodium Oxide. T. V. Rode and G. A. Golder	289	299
7. Scission of the Carbon-Carbon Bond in Compounds Containing the Triphenylmethyl Group. A. N. Nesmeyanov, V. F. Lavrushin, T. M. Shmaeva and E. G. Perevalova	299	309
8. Allyl Rearrangement in Some Substituted Polyhaloallyl Alcohols. L. I. Zakharkin	303	313
9. Organoboron Compounds. Communication 5. Preparation of Isobutyl Esters of Benzeneboronic and Diphenylborinic Acids with the Aid of Phenyllithium. B. M. Mikhailov and P. M. Aronovich	311	322
10. Acylation of Aminoalkyl-Phosphonic and -Phosphonothionic Acids with Chloroformic Esters. T. Ya. Medved and M. I. Kabachnik	315	327
11. Preparation and Reactions of Some Derivatives of 3-Ureidononanoic Acid. V. M. Rodionov and V. K. Zvorykina	319	332
12. Investigation of Hydrogen Bonding in α-Aminonicotine by the Method of Comparing Infrared Absorption Spectra. Ya. L. Goldfarb, M. S. Kondakova and D. N. Shigorin	323	336
13. Composition of the Thiophene-Group Component of the Gaseous Products of the Thermal Decomposition of Kashpir Shales. Ya. L. Goldfarb, G. I. Gorushkina and B. P. Fedorov	327	340
14. High-Temperature Reactions of Decane Over Platinized Alumina in Presence of Hydrogen at High Pressure. Kh. M. Minachev, N. I. Shuikin, L. M. Feofanova, and Yu. P. Egorov	337	352
15. Chemical Changes Produced in the Cellulose Macromolecule by Oxidising Agents. Communication 9. Oxidation of Cellulose by Nitrogen Dioxide. E. D. Kaverzneva, V. I. Ivanov, A. S. Salova and S. A. Kiss	343	358

TABLE OF CONTENTS (continued)

	Page	Russ. Page
16. Formation of Low-Molecular-Weight Polymers of Vinyl Ethers in Presence of Benzoyl Peroxide. M. F. Shostakovsky, E. S. Shapiro and F. P. Sidelkovskaya	351	368
Brief Communications		
17. Preparation of Hexaalkoxydititanoxanes $(R_3O)_3$ Ti-O-Ti $(OR)_3$. A. N. Nesmeyanov, O. V. Nogina and R. Kh. Freidlina	355	373
18. Organoboron Compounds. Communication 6. Action of Phosphorus Pentachloride on Diarylborinic Esters. Synthesis of Diarylchloroborines. B. M. Mikhailov and N. S. Fedotov	359	375
19. Organoboron Compounds. Communication 7. Action of Phosphorus Pentachloride on Areneboronic Esters. Synthesis of Arenechloroboronic Esters. B. M. Mikhailov and T. V. Kostroma	361	376
20. Reactions of Hydrogen Fluoride with Diazo Ketones. I. L. Knunyants, Ya. M. Kisel and E. G. Bykhovskaya	363	377
21. Metathetic Reactions of Acetaldehyde Dibutyl Acetal. M. F. Shostakovsky, N. A. Gershtein and V. A. Neterman	365	378
Current Events		
22. Chemical Conferences in the German Federal Republic. I. Annual Meeting of the German Society for the Investigation of Fats	369	382

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

		Page	Russ. Page
1.	To Nikolai Nikolaevich Semenov	373	385
	General and Inorganic Chemistry		
2.	Kinetics of the Oxidation of Acetaldehyde by Peroxyacetic Acid. R.F. Vasilyev and N.M. Emanuel	375	387
3.	Spectroscopic Study of the Intermediate Product and Intermediate Stage of Reaction in the Oxidation of Acetaldehyde by Peroxyacetic Acid. R.F. Vasilyev, A.N. Terenin and N.M. Emanuel	385	397
4.	Effect of Solvents on the Rate of Oxidation of Acetaldehyde by Peroxyacetic Acid From the Point of View of Intermolecular Hydrogen Bonding. R.F. Vasilyev, A.N. Terenin and N.M. Emanuel	391	403
5.	Kinetic Method of Applying Labeled Atoms in the Investigation of Complex Chemical and Biochemical Processes. Communication 6. Rates of Formation and Transformation of Acetaldehyde, Carbon Monoxide, and Carbon Dioxide in the Oxidation of Propene. M.B. Neiman, V.Ya. Efremov, N.K. Serdyuk and A.F. Lukovnikov	397	408
6.	Criteria for Chain Reactions. V.V. Voevodsky	405	415
7.	Possibility of the Detonation of Gas Mixtures in Conical Tubes. S.M. Kogarko	409	419
8.	Properties of Atoms at Superhigh Pressures. A.F. Kapustinsky	417	427
	Organic and Biological Chemistry		
9.	Decomposition and Formation of Onium Salts, and the Synthesis of Heteroorganic Compounds. Communication 9. Heterolytic Decomposition of Benzenediazonium Fluosilicate. L.G. Makarova and M.K. Matveeva	425	435
10.	Structure of Some Organic Compounds Containing Tin and Phosphorus. B.A. Arbuzov and N.P. Grechkin	429	440
11.	Reaction of O,O-Dialkyl Hydrogen Phosphorodithioates with Vinyl Sulfides. T.A. Mastryukova, E.N. Prilezhaeva, N.I. Uvarova, M.F. Shostakovsky and M.I. Kabachnik	433	443
12.	Organoboron Compounds. Communication 8. Synthesis and Properties of Diarylboric Acids. B.M. Mikhailov and V.A. Vaver	441	451
13.	Synthesis of ar-Chlorine-Substituted Dichloroethylphenylsilanes. K.A. Andrianov and V.A. Odinets	447	457
14.	Wurtz Synthesis of Organosilicon Compounds Having a Double Bond in the α-Position. A.D. Petrov, V.F. Mironov and V.G. Glukhovtsev	451	461

TABLE OF CONTENTS (continued)

		Page	Russ. Page
15.	Catalytic Hydrocondensation of Carbon Monoxide with Olefins. Communication 14. Interconversion of 1- and 2-Butenes Under the Conditions of Catalytic Hydrocondensation of Carbon Monoxide with Olefins. Ya.T. Eidus and R.I. Izmailov	457	467
16.	Catalytic Hydrocondensation of Carbon Monoxide with Olefins. Communication 15. Hydrocondensation of Carbon Monoxide with 2-Butene. Ya.T. Eidus and R.I. Izmailov	465	475
17.	Chemical Changes Produced in the Cellulose Macromolecule by Oxidizing Agents. Communication 10. Oxidation of Hydroxy Compounds of Low Molecular Weight with Nitrogen Dioxide. E.D. Kaverzneva, V.I. Ivanov and A.S. Salova	473	482
18.	New Data on the Hofmann Reaction. Communication 4. Action of Hypobromite on Diastereoisomeric 3-(Acylamino)-4-Ethyloctanamides. V.M. Rodionov, V.K. Zvorykina and N.E. Kozhevnikova	483	491
19.	Chloromethylation of 2,5-Dimethylthiophene. Ya.L. Goldfarb and M.S. Kondakova.	487	495
	Brief Communications		
20.	Ion Exchange on Cellulose and Its Derivatives. V.I. Ivanov and N.Ya. Lenshina	497	506
21.	Organoboron Compounds. Communication 9. Action of Phosphorus Pentachloride on Dialkylborinic and Alkaneboronic Esters. Synthesis of Dialkylchloroborines and Alkanechloroboronic Esters. B.M. Mikhailov and T.A. Shchegoleva	501	508
22.	Tertiary Alkyl Fluorides and Alkylene Difluorides in Organomagnesium Synthesis. A.D. Petrov, V.L. Sushchinsky and M.P. Shebanova	503	510

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

	Page	Russ. Page
General and Inorganic Chemistry		
1. Rapid Nonionic Metathetic Reactions in a Nonaqueous Medium. Yu. M. Kessler	507	513
2. Reaction of Deuterium Atoms with Alkenes. Dependence of the Extent of the Deuteration of Methane on the Concentration of Deuterium Atoms in the System. R. E. Mardaleishvili, G. B. Parlisky, V. A. Poltorak, and V. V. Voevodsky	511	516
3. Coke Formation on Aluminosilicate Cracking Catalysts. B. V. Klimenok, E. A. Andreev, and V. A. Gordeeva	521	525
4. Determination of π-Electron Density and Interatomic Distances. Communication 3. Confirmation of the Hypothesis. G. V. Bykov	527	531
Organic and Biological Chemistry		
5. Organophosphorus Ethylenimine Derivatives. Communication 1. Reaction of Ethylenimine with Dialkyl Phosphorochloridates. N. P. Grechkin	535	538
6. Action of Active Nitrogen on Organic Substances. Communication 1. P. M. Aronovich B. M. Mikhailov	541	544
7. Dehydrochlorination of Trichloro(chloroalkyl)- and Trichloro(dichloroalkyl)-Silanes. Rearrangement of 1,1,1,2,4,4,4-Heptachloro-1,4-disilabutane during Dehydrochlorination with Aluminum Chloride. A. D. Petrov, V. F. Mironov, and D. Mashantsker	547	550
8. Stereochemistry of Cyclic Compounds. Communication 9. Condensation of 1-Vinyl-1-cyclohexene with Methyl Acrylate. I. N. Nazarov, V. F. Kucherov, and G. M. Segal	557	559
9. Synthesis of Steroid Compounds and Related Substances. Communication 37. Synthesis of Steroid Analogs Not Containing A B Ring. I. N. Nazarov and S. I. Zavyalov	567	569
10. Reduction of β-Amino Acids with Lithium Aluminum Hydride. V. M. Rodionov and V. V. Kiseleva	573	575
11. Some Reactions of β-Amino-1-naphthalenepropionic Acid and β-Methylaminio-1-naphthalenepropionic Acid. V. M. Rodionov and L. V. Antik	577	578
12. Chlorination of Alkanes in Presence of Nitrogen Dioxide. V. A. Nekrasova and N. I. Shuikin	583	583
13. Relative Activities of Nickel, Zinc, and Chromium Oxides, Sulfides, and Selenides in the Catalytic Decomposition of Isopropyl Alcohol. A. M. Rubinshtein, S. G. Kulikov, and B. A. Zakharov	587	587
14. Activities of Nickel, Zinc, and Chromium Oxides, Sulfides, and Selenides in the Reduction of Nitrobenzene and the Selective Hydrogenation of a Diolefin into an Olefin. A. M. Rubinshtein, A. A. Dulov, S. G. Kulikov, and N. A. Pribytkova	595	596

TABLE OF CONTENTS (continued)

	Page	Russ. Page
15. Chemical Changes Produced in the Cellulose Macromolecule by Oxidizing Agents. Communication 11. Causes of the Chemical Instability of Celluloses Oxidized with Nitrogen Dioxide. E. D. Kaverzneva and S. A. Kist	603	604
16. Application of the Iodoform Reaction to the Analysis of Some Vinyl Compounds M. F. Shostakovsky, F. P. Sidelovskaya, and M. G. Zelenskaya	615	615
Brief Communications		
17. Use of a Nickel Catalyst in the Kizhner Decomposition of Hydrazones. N. I. Shuikin, I. E. Grushko, and I. F. Belsky	623	622
18. Sulfonation of tert-Butyl-Substituted Thiophenes. Ya. L. Goldfarb, L. V. Antik, and P. A. Konstantinov	627	624
19. Differential Titration of Tripeptides and Piperazinediones in the Polycondensation Products from Glycine Ethyl Ester. K. T. Poroshin, T. D. Kozarenko, and Yu. I. Khurgin	631	626
20. Addition of CH_3SiHCl_2 and $C_2H_5SiHCl_2$ to Chloro-, Chlorotrifluoro-, and Tetrafluoro-Ethylenes. V. A. Ponomarenko, B. A. Sokolov, and A. D. Petrov	633	628
21. Reactions of Trichlorosilane and Dichloromethylsilane with Benzene. E. A. Chernyshev and A. D. Petrov	637	630
22. Synthesis and Reactions of Oxygen-Containing Organosilicon Compounds. Communication 3. Reaction of Propylene Oxide with Alkyl- and Aryl-Chlorosilanes. M. F. Shostakovsky, M. S. Malinovsky, M. K. Romantsevich, and D. A. Kochkin	639	632
Chronicle		
23. Hungarian Chemical Congress	643	635

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

	Page	Russ. Page
General and Inorganic Chemistry		
1. Phase Diagram of the Ternary System CaO-BaO-SiO_2. N. A. Toropov, F. Ya. Galakhov, and I. A. Bondar	651	641
2. The Densities of Aqueous Uranyl Nitrate Solutions, and the Apparent Molar Volumes of Uranyl Nitrate. A. F. Kapustinsky and L. I. Lipilina	661	649
3. Kinetics of the Oxidation of Ethane in Presence of Hydrogen Bromide. M. F. Sedova and N. M. Emanuel	669	658
4. Relation Between the Catalytic Activity of Binary Compounds of Group II Metals with Nonmetals and the Positions of the Elements in Mendeleev's Periodic System. Communication 1. Catalytic Decomposition of Isopropyl Alcohol over Alkaline-Earth Oxides. O. V. Krylov, S. Z. Roginsky, and E. A. Fokina	679	668
Organic and Biological Chemistry		
5. 2- Aminovinyl Ketones. Communication 5. Alkylation of 2-Dialkylaminovinyl Ketones. New Synthesis of Hydroxymethylene Ketones. N. K. Kochetkov, M. G. Ivanova, and A. N. Nesmeyanov	687	676
6. o-Phenylene Esters of Pyrophosphorous Acid. A. E. Arbuzov and F. G. Valitova	691	681
7. Derivatives of 1-Aminoalkylphosphonic Acids. 1-Isocyanatoalkylphosphonic Esters and Their Reactions. T. Ya. Medved and M. I. Kabachnik	695	684
8. Organoboron Compounds. Communication 10. Complex Nature of Salts of Organoboron Acids. B. M. Mikhailov, T. K. Kozminskaya, A. N. Blokhina, and T. A. Shchegoleva	703	692
9. Action of Active Nitrogen on Organic Substances. Communication 2. P. M. Aronovich, N. K. Belsky, and B. M. Mikhailov	707	696
10. Synthesis of Alkoxy- and Acetoxy-Silanes Containing an Ether or Ester Grouping Substituted in Silicon-Attached Alkyl. K. A. Andrianov and L. I. Makarova	713	702
11. Synthesis and Reactions of Organosilicon Thiocyanates and Thiols. V. F. Mironov and N. A. Pogonkina	719	707
12. Reaction of Hexaalkyldisiloxanes with Iodine and Aluminum. M. G. Voronkov and Yu. I. Khudobin	725	713
13. Stereochemistry of Cyclic Compounds. Communication 10. Stereochemistry of the Diene Condensation of 1-Vinyl-1-Cyclohexene with Maleic Anhydride. I. N. Nazarov, V. F. Kucherov, and V. M. Andreev	727	715

TABLE OF CONTENTS (continued)

	Page	Russ. Page
14. Catalytic Hydrocondensation of Carbon Monoxide with Olefins. Communication 16. Hydrocondensation of Carbon Monoxide with 1-Butene. Ya. T. Eidus and S. I. Izmailov	733	723
15. Thermal Reactions of Tetrachloroethylene at Superhigh Pressures. M. G. Gonikberg, V. M. Zhulin, and V. P. Butuzov	739	730
16. Esterification in Presence of Boric Acid, and the Synthesis of Boric Esters. V. K. Kuskov and V. A. Zhukova	743	733
Brief Communications		
17. Breakdown of the Ferrocene Nucleus by Hydrogenation and the Action of Halogens. A. N. Nesmeyanov, E. G. Perevalova, R. V. Golovnya, T. V. Nikitina, and N. A. Simukhova	749	739
18. Preparation of Bicyclo[2·2·1]Hepta-2,5-Diene by the Condensation of Cyclopentadiene with Acetylene. A. F. Plate and M. A. Pryanishnikova	753	741
19. Some Peculiar Features of the Polymerization of Anhydrides of α-Carboxyamino Acids. K. T. Poroshin	755	743
20. Di-2-Thienylmethanol. Ya. L. Goldfarb and M. L. Kirmalova	759	746
21. Opening of the Tetrahydrofuran Ring Under the Action of Aluminum Halides. N. I. Shuikin and I. F. Belsky	761	747
Current Events		
22. Annual Meeting of the Division of Chemical Sciences of the Academy of Sciences of the USSR	763	749

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

	Page	Russ. Page
1. Fiftieth Birthday Greetings to Ivan Lyudvigovich Knunyants	769	753
2. Fiftieth Birthday Greetings to Ivan Nikolaevich Nazarov	770	754
General and Inorganic Chemistry		
3. Colloidal Properties of Polonium. L. E. Starik, N. I. Alekseenko, and N. G. Rozovskaya	771	755
4. Concentration Limits for Flame Propagation in Mixtures of Hydrogen and Oxides of Nitrogen. E. A. Blyumberg, A. N. Pomansky, and N. M. Emanuel	779	764
5. Phase Diagram of the Binary System Titanium-Aluminum. I. I. Kornilov, E. N. Pylaeva, and M. A. Volkova	787	771
6. Effect of Temperature on the Diffusion Current and the Thickness of the Diffusion Layer. V. V. Gerasimov and I. L. Rozenfeld	797	779
7. Effect of Steam and Compression Treatments on the Macrostructure and Catalytic Activity of Alumina. I. E. Neimark, L. Kh. Freidlin, A. I. Rastrenenko, and N. V. Borunova	803	784
Organic and Biological Chemistry		
8. Trialkyl Phosphorimidates. Trialkyl Phenylphosphorimidates. M. I. Kabachnik and V. A. Gilyarov	809	790
9. Polyorganostanno- and Polyorganotitano-Siloxanes. K. A. Andrianov, T. N. Ganina, and E. N. Khrustaleva	817	798
10. Reaction of Trialkylsilanes with Iodine and Hydrogen Iodide. M. G. Voronkov and Yu. I. Khudobin	823	805
11. Synthesis and Reactions of Oxygen-Containing Organosilicon Compounds. Communication 4. Synthesis of the Methyl, Ethyl, Propyl, and Isopropyl Dimethylphenylsilyl Acetals of Acetaldehyde. M. F. Shostakovsky and Kh. I. Kondratyev	829	811
12. Stereochemistry of Cyclic Compounds. Communication 11. Stereochemistry of 1,2,3,5,6,7,8,8a-Octahydro-1,2-Naphthalenedicarboxylic Acids. N. Nazarov, V. F. Kucherov, and V. M. Andreev	835	817
13. Acetylene Derivatives. Communication 175. Alcoholysis of 2-Cyanoethyl Ethers of Acetylenic Alcohols. I. N. Nazarov and G. A. Shvekhgeimer	845	827

TABLE OF CONTENTS (continued)

TABLE OF CONTENTS

	Page	Russ. Page
1. Part of the Five-Component System, Nickel-Chromium-Tungsten-Titanium-Aluminum. I. I. Kornilov, L. I. Pryakhina and O. V. Ozhimkova	907	885
2. Thermal Analysis of the System, Benzene-Stannic Bromide. A. F. Kapustinsky and Yu. M. Kessler	911	889
3. Solubility of Silicic Acid. Yu. V. Morachevsky and M. M. Piryutko	917	894
4. Reaction Between the Ether Complex of Boron Trifluoride and Lithium Hydride. Communication 1. Preparation of Pure Diborane. V. I. Mikheeva and E. M. Fedneva	925	902
5. Mechanism of the Deactivation of Nickel Catalysts by Steam Under Pressure. L. Kh. Freidlin, A. A. Balandin, N. V. Borunova and A. E. Agronomov	935	913
6. Derivatives of Unsaturated Phosphonic Acids. Communication 19. 2-Chloro-3-butenyl- and 1,3-Butadienyl-phosphonic Esters. K. N. Anisimov and N. E. Kolobova	943	923
7. Derivatives of Unsaturated Phosphonic Acids. Communication 20. 2-Chloro-3-methyl-3-butenyl- and 3-Methyl-1,3-butadienyl-phosphonic Esters. K. N. Anisimov and N. E. Kolobova	947	927
8. Alkylamides of Organic Derivatives of Phosphorus Acids. B. A. Arbuzov, P. I. Alimov and O. N. Fedorova	953	932
9. Acyl Derivatives of 1-Hydroxyalkylphosphonic Esters. P. I. Alimov and I. V. Cheplanova	959	939
10. Mechanism of Reactions Between Diazo Compounds and Metals with Formation of Organometallic Compounds. O. A. Reutov	963	943
11. Stereochemistry of Cyclic Compounds. Communication 12. Stereochemistry of Lactones of 1,2,3,5,6,7,8,8a-Octahydro-1,2-naphthalenedicarboxylic Acids. I. N. Nazarov, V. F. Kucherov and V. M. Andreev	971	951
12. Acetylene Derivatives. Communication 174. Condensation of Aldehydes and Ketones with Acetylene Under Pressure. II. I. N. Nazarov, I. L. Kotlyarevsky and V. F. Ryabchenko	979	960
13. Synthesis and Reactions of Oxygen-Containing Organosilicon Compounds. Communication 5. Synthesis and Reactions of Aliphatic-Aromatic Silanediols. M. F. Shostakovsky and Kh. I. Kondratyev	985	967
14. Kinetics and Chemistry of the Polycondensation of Glycine Ethyl Ester. K. T. Poroshin, T. D. Kozarenko and Yu. I. Khurgin	993	974
15. Polymerization and Copolymerization of Alkenylsilanes Under High Pressure. Communication 3. A. M. Polyakova, V. V. Korshak, A. A. Sakharova, A. D. Petrov, V. F. Mironov and G. I. Nikishin	999	979

TABLE OF CONTENTS (continued)

	Page	Russ. Page
16. Alkylation and Dealkylation of Benzene and its Homologs in Presence of Aluminosilicates, Yu. G. Mamedaliev and G. M. Mamedaliev	1007	986
17. Synthesis of Aliphatic Alcohols from Thiophene and its Homologs, Ya. L. Goldfarb and P. A. Konstantinov	1013	992
18. Physical Properties of Some Isodurene Homologs, A. L. Liberman, M. A. Pryanishnikova and B. A. Kazansky	1021	1000
19. Efficiencies of Various Catalysts in the Alkylation of Benzene with Propene, Ya. M. Paushkin and M. V. Kurashev	1027	1006
20. Quantitative Investigation of Steric Hindrance, C. K. Ingold	1037	1016

TABLE OF CONTENTS

	Page	Russ. Page
General and Inorganic Chemistry		
1. Principles Underlying New Methods for the Chemical Treatment of Complex Iron and Nickel Ores. G. G. Urazov and D. P. Bogatsky	1047	1029
2. Surface and Sorption Properties of Active Carbons. Communication 2. Investigation of the Effect of Chemically Adsorbed and Chemisorbed Oxygen on the Adsorption Properties of Active Carbons With Respect to Water Vapor. M. M. Dubinin and E. D. Zaverina	1055	1038
3. Efficiency of Protector Blocks of Aluminum-Zinc Alloys. V. V. Gerasimov and I. L. Rozenfeld	1065	1050
Organic and Biological Chemistry		
4. Synthesis of Alkenyl 2-Chlorovinyl Ketones. N. K. Kochetkov, A. Ya. Khorlin, B. P. Gottikh and A. N. Nesmeyanov	1069	1053
5. Synthesis and Properties of (Triphenylsiloxy)Silanes and Their Hydrolysis Products. V. S. Chugunov	1075	1059
6. Synthesis and Reactions of Oxygen-containing Organosilicon Compounds. Communication 6. Preparation of Secondary Dialkyl(or Aryl)Chlorosilanes and Dialkyl(or Aryl) Silanols and Some of Their Reactions. M. F. Shostakovsky, D. A. Kochkin and V. M. Rogov	1079	1062
7. Optical Investigation of Tetraethylsilane and Chloro(Ethyl)Silanes and the Behavior of these Compounds in Chlorination. M. I. Batuev, A. D. Petrov, V. A. Ponomarenko and A. D. Matveeva	1087	1070
8. Polyenic Compounds. Communication 1. Synthesis of 1,5-Diaryl-1,3,5-hexatrienes. B. M. Mikhailov and G. S. Ter-Sarkisyan	1095	1079
9. Reaction of Silacyclopentanes and Silacyclohexanes with Concentrated Sulfuric Acid. A. F. Plate, N. A. Belikova and Yu. P. Egorov	1101	1085
10. Stereochemistry of Cyclic Compounds. Communication 13. Synthesis and Stereochemistry of Isomeric Decahydro-1,2-Naphthalenedicarboxylic Acids. I. N. Nazarov, V. F. Kucherov and V. M. Andreev	1107	1091
11. Hydrogenation of Isopropenylcyclopropane in Presence of Platinum Black. B. A. Kazansky, M. Yu. Lukina, A. I. Malyshev, V. T. Aleksanyan and Kh. E. Sterin	1119	1102
12. Investigation of the Composition of the Naphthene Part of the Kerosene Fraction of Tuimazin (Devonian) Petroleum. A. V. Topchiev, L. M. Rozenberg, M.M. Kusakov and M. V. Shishkina	1127	1109
13. Copolymerization of Dienic Hydrocarbons with Vinyl Ethers. Communication 1. Peculiar Features of the Copolymerization of Chloroprene with Vinyl Ethers. S. P. Mitsengendler, V. N. Krasulina and L. B. Trukhmanova	1137	1120

TABLE OF CONTENTS (continued)

	Page	Russ. Page
14. Optical Method of Investigating Hydrocarbons. Communication 9. Raman Spectra of Some Naphthenes. P. A. Bazhulin, A. L. Sokolovskaya, N. A. Belikova, A. L. Liberman and A. F. Plate	1147	1130
15. Catalytic Polymerization of Propene Under Pressure. L. L. Antuz and A. D. Petrov	1153	1135
Brief Communications		
16. Physical Properties of cis-1,3,5-Trimethylcyclohexane. A. L. Liberman, M. A. Pryanishnikova and B. A. Kazansky	1161	1142
17. Organoboron Compounds. Communication 12. Synthesis of Aryldichloroborines. B. M. Mikhailov and T. V. Kostroma	1165	1144
18. Synthesis of Unsaturated Organogermanium Compounds. A. D. Petrov, V. F. Mironov and I. E. Golgy	1169	1146
19. Preparation of Cyclopentene from Cyclopentadiene. A. F. Plate and V. I. Stanko	1173	1148
20. Synthesis and Reactions of Vinyl Compounds of Silicon. Communication 2. Catalytic Vinylation of Halo- and Alkyldihalo-silanes Containing Silicon-attached Hydrogen. M. F. Shostakovsky and D. A. Kochkin	1175	1150
21. Role of Hydrogen Disulfide in the Vulcanization Process. E. I. Tinyakova, E. K. Khrennikova and B. A. Dolgoplosk	1179	1152
Current Events		
22. Second Joint Scientific Session of the Chemical Institutes of the Transcaucasian Academies of Sciences	1183	1155

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

	Page	Russ. Page
1. Salutation to Semen Isaakovich Volfkovich	1185	1157
General and Inorganic Chemistry		
2. "Complex" Reduction of Multimetal Iron and Nickel Ores as a Basis for New Methods for Their Chemical Treatment. G. G. Urazov and D. P. Bogatsky	1187	1159
3. Electron-Microscope Investigation of Polish Sandomir Silicas. E. A. Leontyev, V. M. Lukyanovich, and Z. Ya. Sokalsky	1195	1168
4. Stagewise Character of the Hydrogenation of the Double Bonds of Cyclopentadiene Over Raney Nickel. L. Kh. Freidlin and B. D. Polkovnikov	1199	1171
5. Catalytic Activity and Acidity of Silica Gel Treated with Solutions of Aluminum Salts. K. G. Miesserov	1207	1180
6. Investigation with the Aid of Labeled Atoms of the Conditions Required for the Separation of Zinc and Cobalt from Aluminum and Iron. Yu. V. Morachevsky and Z. S. Bashun	1213	1185
Organic and Biological Chemistry		
7. Condensation of 2-Chlorovinyl Ketones with Benzene and Its Homologs. A. N. Nesmeyanov, M. I. Rybinskaya, and N. K. Kochetkov	1225	1197
8. Action of Chlorine on Unsaturated Polychloro Compounds in an Acid Medium. R. Kh. Freidlina, V. N. Kost, and A. N. Nesmeyanov	1229	1202
9. Action of Water on 3,4-Bischloromethyl-2,5-Dimethylthiophene. Ya. L. Goldfarb and M. S. Kondakova	1235	1208
10. Stereochemistry of Cyclic Compounds. Communication 14. Condensation of 1-(1-Acetoxyvinyl)Cyclohexene with Methyl Acrylate. I. N. Nazarov, V. F. Kucherov, and G. M. Segal	1241	1215
11. Acetylene Derivatives. Communication 176. Synthesis of 2-Carboxyethyl Ethers of Acetylenic Alcohols and of Their Acid Chlorides and Amides. I. N. Nazarov and G. A. Shvekhgeimer	1247	1221
12. Free-Radical Polymerization and Copolymerization of 2-Butoxyethyl Vinyl Sulfide. M. F. Shostakovsky, E. N. Prilezhaeva, and A. M. Khomutov	1257	1230
13. Oligomerization. Communication 1. Reaction of Some Vinyl Ethers with Carbon Tetrachloride. M. F. Shostakovsky, A. V. Bogdanova, M. M. Zverov, and G. I. Plotnikova	1263	1236
14. Optical Investigation of the Si—H Bond and Peculiarties in Its Chemical Behavior in Various Compounds. M. I. Batuev, A. D. Petrov, V. A. Ponomarenko, and A. D. Matveeva	1269	1243

TABLE OF CONTENTS (continued)

	Page	Russ. Page
15. Thermal Transformations of Piperylene at Various Pressures. N. I. Shuikin and T. I. Naryshkina	1277	1249
16. Effect of the Method of Preparation and the Presence of a Carrier on the Catalytic Activity of Chromic Oxide in Dehydrogenation and Dehydration Reactions. A. A. Tolstopyatova, K. A. Dulitskaya, and A. A. Balandin	1285	1256
Brief Communications		
17. Main Direction of Reaction in the Thermal Decomposition of Cellulose in a Vacuum. V. I. Ivanov, O. P. Golova, and A. M. Pakhomov	1295	1266
18. Synthesis of 2-Cyclopentyloctane and 5,5-Dimethylundecane. G. A. Tarasova, G. S. Taits, and A. F. Plate	1297	1267
19. Synthesis and Reactions of Oxygen-Containing Organosilicon Compounds. Communication 6. Reaction of Alcohols with Alkyl- and Aryl-Dichlorosilanes Containing Silicon-Attached Hydrogen. M. F. Shostakovsky, D. A. Kochkin, V. L. Vinogradov, and V. A. Neterman	1301	1269
20. Synthesis and Reactions of Unsaturated Organosilicon Compounds. Communication 1. Synthesis and Reactions of Tertiary Organosilicon Acetylenic Alcohols. M. F. Shostakovsky, I. A. Shikhiev, and N. V. Komarov	1305	1271
21. Catalytic Hydrogenation of Isopropyl and Isopropenyl-Cyclobutane. B. A. Kazansky, M. Yu. Lukina, and L. A. Nakhapetyan	1309	1274
22. Synthesis of Aliphatic Amino Dicarboxylic Acids from Thiophene. Ya. L. Goldfarb, B. P. Fabrichny, and I. F. Shalavina	1311	1276
Current Events		
23. All-Union Conference on the Application of Isotopes in Catalysis	1315	1279

Bulletin of the Academy of Sciences of the U.S.S.R.

November, 1956

TABLE OF CONTENTS

	Page	Russ. page
1. Cathode Processes Occurring in the Electrodeposition of Thorium from Fused Electrolytes. M. V. Smirnov and L. D. Yushina	1321	1285
2. Application of the Dynamic Method of Measuring Adsorption of Vapors to the Determination of the Surface Area of Catalysts. A. M. Rubinshtein and V. A. Afanasyev	1329	1294
3. Heat of Adsorption of Benzene Vapor on Carbon Blacks. Thermodynamics of the Process and the Adsorption Forces. N. N. Avgul, G. I. Berezin, A. V. Kiselev, and I. A. Lygina	1339	1304
4. Hydrogenation of Cyclopentadiene in Binary Mixtures with other Unsaturated Hydrocarbons in Presence of Raney Nickel. L. Kh. Freidlin and B. D. Polkovnikov	1347	1312
5. Determination of Fluorine in Silicates. Yu. V. Morachevsky and E. N. Egorova	1355	1320
6. Physical Basis of the Reactivity of Carbonyl Compounds. M. I. Batuev	1363	1329
7. Attempt to Set up a Semiquantitative Theory of Mutual Effects of Atoms in Organic Compounds. Communication 1. Electronic Charges of Bonds, Electronegativities of Atoms, and the Heats of Formation of Saturated Hydrocarbons. G. V. Bykov	1375	1342
8. Reactions of Fluoro Olefins. Communication 6. Reactions of Perfluoroisobutene and Perfluoropropene with Nucleophilic Reagents. I. L. Knunyants, L. S. German, and B. L. Dyatkin	1387	1353
9. Structure of Compounds Formed from Thiophene and 2-Methylthiophene under the Conditions of Chloromethylation in Presence of Zinc Chloride. Ya. L. Goldfarb and Ya. L. Danyushevsky	1395	1361
10. Acetylene Derivatives. Communication 177. Condensation of Aromatic and Aliphatic-Aromatic Ketones with Acetylene under Pressure. Part III. I. N. Nazarov and V. F. Ryabchenko	1403	1370
11. Acetylene Derivatives. Communication 178. 2-Cyanoethyl Ethers of Acetylenic Alcohols Containing Aromatic Substituents. I. N. Nazarov and G. A. Shvekhgeimer	1410	1378
12. α-Keto Epoxides and Their Reactions. Communication 6. α-Keto Epoxides from Cyclic Ketones. I. N. Nazarov and A. A. Arkhem	1415	1383
13. Demethylation and Isomerization of o-Xylene Over Aluminosilicates. A. V. Topchiev, G. M. Mamedaliev and Yu. G. Mamedaliev	1421	1390

TABLE OF CONTENTS (continued)

	Page	Russ. page
14. Catalytic Vapor-Phase Hydrogenation of Isopropylcyclopropane and Isopropenylcyclopropane. B. A. Kazansky, M. Yu. Lukina, and A. I. Malyshev	1431	1399
15. Kinetics of the Dehydrogenation of Isopropyl and Ethyl Alcohols over Manganous Oxide. A. A. Tolstopyatova, A. A. Balandin, and E. M. Dmitriev	1437	1404
Brief Communications		
16. Coordination Numbers of Rb^+ and Cs^+ Ions in Aqueous Solutions. O. Ya. Samoilov	1449	1415
17. Heat of Atomization of Carbon. G. V. Bykov	1451	1416
18. Synthesis of Cancerolytic Peptides. I. L. Knunyants, O. V. Kildisheva, and N. E. Golubeva	1455	1418
19. Cis-Trans Isomerism of 1,2-Bistrichlorosilylethylene. M. I. Batuev, V. A. Ponomarenko, A. D. Matveeva, and A. D. Snegova	1457	1420
20. Isomerization of Isopropenylcyclobutane on Silica Gel Under the Conditions of Chromatographic Adsorptional Analysis. B. A. Kazansky, M. Yu. Lukina, L. A. Nakhapetyan, V. T. Aleksanyan, and Kh. E. Sterin	1459	1421
Current Events		
21. Second Conference on Methods of Investigating the Structure of Highly Dispersed and Porous Bodies. V. M. Lukyanovich	1461	1423
22. Congress of Austrian and German Chemists. M. A. Klochko	1464	1426
Erratum	1	

Bulletin of the Academy of Sciences of the U.S.S.R.

TABLE OF CONTENTS

	Page	Russ. Page
1. Interphase Partition in Systems Containing Anomalous Mixed Crystals. Communication 5. The Systems $NH_4Cl-CdCl_2-H_2O$ and $NH_4Cl-NiCl_2-H_2O$. E. M. Ioffe	1469	1429
2. Attempt to Set up a Semiquantitative Theory of Mutual Effects of Atoms in Organic Compounds. Communication 2. Electronic Charges of Bonds and Physical Properties of Molecules. G. V. Bykov	1475	1435
3. Synthesis of Organosilicon Compounds Containing Carbonyl and Carboxyl Groups. A. D. Petrov, E. A. Chernyshev and M. Bisku	1485	1445
4. Polyenic Compounds. Communication 2. Polyenic Compounds Containing Heterocyclic Substituents. B. M. Mikhailov and G. S. Ter-Sarkisyan	1489	1448
5. Synthesis of Steroid Compounds and Related Substances. Communication 38. Analogs of Doisynolic Acid Not Containing a B Ring. I. N. Nazarov and S. I. Zavyalov	1493	1452
6. α-Keto Epoxides and their Reactions. Communication 7. Geometric Isomerism in the α-Keto Diepoxide Series. I. N. Nazarov and A. A. Arkhem	1499	1457
7. Stereochemistry of Cyclic Compounds. Communication 15. Condensation of 2-Methoxy-1,3-Butadiene with Maleic and Citraconic Anhydrides and with the Methyl Esters of Fumaric and Mesaconic Acids. I. N. Nazarov and V. F. Kucherov	1505	1462
8. Mechanism of Hydration and Dehydration Reactions in Presence of Zinc Halides. A. B. Kuchkarev and N. I. Shuikin	1511	1469
9. Oxidation-Reduction Systems for the Initiation of Free-Radical Processes. Communication 1. Reversible Systems in which Organic Hydroperoxides, Dienols, and Salts of Metals of Variable Valence Take Part. G. P. Belonovskaya, B. A. Dolgoplosk, and E. I. Tinyakova	1521	1478
10. Chloromethylation of Toluene. I. N. Nazarov and A. V. Semenovsky	1529	1487
11. Synthesis and Reactions of Oxygen-Containing Organosilicon Compounds. Communication 3. Synthesis and Some Reactions of Vinyl Ethers of 3-(Trimethylsilyl)- and 3-(Diethylmethylsilyl)-1-Propanol. M. F. Shostakovsky, I. A. Shikhiev and N. V. Komarov	1535	1493
BRIEF COMMUNICATIONS		
12. Kinetics and Chemistry of the Polycondensation Esters of α-Amino Acids. Communication 4. Copolycondensation of Glycine Ethyl Ester and N-Carboxyglycine Anhydride. K. T. Poroshin, T. D. Kozarenko and Yu. I. Khurgin	1543	1500
13. Effect of Pyridine on the Rate and Selectivity of the Hydrogenation of Diphenylacetylene and Cyclopentadiene over Raney Nickel and Platinum Black. L. Kh. Freidlin and B. D. Polkovnikov	1547	1502

TABLE OF CONTENTS (continued)

	Page	Russ. Page
14. Determination of Specific Surfaces of the Components of Mixed $MgO-Cr_2O_3$ Catalysts. A. M. Rubinshtein, V. A. Afanasyev and N. A. Pribytkova.	1551	1505
15. Synthesis of C^{14}-Labeled Toluene. A. A. Korotkov and S. P. Mitsengendler.	1555	1507
16. Synthesis of C^{14}-Labeled Benzene. A. A. Korotkov and S. P. Mitsengendler.	1557	1509
17. Organoboron Compounds. Communication 14. Action of Organic Bases on Chlorodiphenylborine. B. M. Mikhailov and N. S. Fedotov.	1561	1511

Acetylene derivatives. Alcoholysis of 2-cyanoethyl ethers of acetylenic alcohols, to the corresponding methyl esters, 845;

—Condensation of aldehydes and ketones with acetylene under pressure, in presence of potassium hydroxide powder, to form secondary and tertiary acetylenic alcohols, 979;

—Condensation of aromatic and aliphatic-aromatic ketones with acetylene under pressure to form the corresponding tertiary acetylenic alcohols, 1403;

—Cyanoethylation of acetylenic alcohols, 191;

—2-Cyanoethyl ethers of acetylenic alcohols containing aromatic substituents, preparation, properties, reactions, 1410;

—Polyenic compounds containing heterocyclic substituents (quinoline, pyridine), preparation, reaction, 1489;

—Synthesis of 2-carboxyethyl ethers of acetylenic alcohols and their acid chlorides and amides, 1247;

—Synthesis of 1, 5-diaryl-1, 3, 5-hexatrienes, 1095;

—Tertiary organosilicon acetylenic alcohols, see silicon organic compounds.

Acetylene, diphenyl, hydrogenation over Raney nickel and platinum black, effect of pyridine on the rate and selectivity of, 1547.

Acid, peroxyacetic, as oxidizing agent for acetaldehyde, 375, 385, 391;

—Pyrophosphorous, o-phenylene esters of, see esters;

—Styrylphosphonic, derivatives of (diamides, diesters), preparation, properties, 17;

—3-ureidononanoic, derivatives, preparation, reactions, 319;

Acids, acetic, oleic, stearic, reaction with active nitrogen, 541;

—α-acylamino β-halo carboxylic (N-benzoyl-3-chloro-2-hydroxyvaline), decarboxylation (to N-isobutyrylbenzamide), 871;

—Aliphatic amino dicarboxylic, synthesis from thiophene, 1311;

—Aminoalkyl-phosphonic and -phosphonothionic; see phosphorus organic compounds;

—1-aminoalkylphosphonic, derivatives of 1-isocyanatoalkylphosphonic esters, preparation, reactions, 695;

—β-amino-1-naphthalenepropionic and β-methylamino-1-naphthalenepropionic, reactions of, 577;

—Diarylborinic, synthesis and properties of, 441;

—α, β-disubstituted α-acylamino carboxylic, preparation, properties, 853;

—Isomeric decahydro-1,2-naphthalenedicarboxylic, synthesis and stereochemistry of, 1107;

—1,2,3,5,6,7,8,8a-octahydro-1,2-naphthalenedicarboxylic, stereochemistry of, 835;

—1,2,3,5,6,7,8,8a-octahydro-1,2-naphthalenedicarboxylic acid, lactones of, see lactones;

—Organoboron, complex nature of salts of, 703;

—Phosphonic, derivatives of, 2-(alkylthio) vinylphosphonic dichlorides and their derivatives, preparation properties, 21;

—Phosphonic, unsaturated, derivatives of, Diesters of 2-indenylphosphonic acid, preparation, properties, 13.

Acrylonitrile, for cyanoethylation of acetylenic alcohols, 191.

Acylals, mercurated, preparation, properties, 173.

Acylation, of aminoalkyl-phosphonic and -phosphonothionic acids with chloroformic esters, 315.

Adsorption, heat of, of benzene vapor on carbon blacks. Thermodynamics of the process and adsorption forces, 1339;

—Of polar and non-polar substances, on quartz, isotherms for, 145;

—Of vapors, dynamic method of measurement of, application to the determination of the surface areas of catalysts, 1329;

—Of vapors on quartz. Method of investigating adsorption isotherms, 3
Adsorption properties, of active carbons. Effect of chemically adsorbed and chemisorbed oxygen on the adsorption properties, with respect to water vapor, 1055.
Agricultural chemistry. Alkylamides of organic derivatives of phosphorus acids, 953;
— Ion exchange on cellulose and its derivatives, 497;
—Preparation of bicyclo [2,2,1] hepta-2,5-diene by the condensation of cyclopentadiene with acetylene, 753.
Alcohol, isopropyl, catalytic decomposition over alkaline earth oxides, 679.
—Isopropyl, relative activities of nickel, zinc and chromium oxides, sulfides and selenides in the catalytic decomposition of, 587.
Alcohols, reaction with alkyl- and aryl- dichlorosilanes containing silicon-attached hydrogen, 1301;
—Acetylenic, see acetylene derivatives;
—Acetylenic, tertiary organosilicon, see silicon organic compounds;
—Aliphatic, synthesis from thiophene and its homologs, in presence of Raney nickel, 1013;
—Isopropyl, ethyl, kinetics of dehydrogenation over manganous oxide, 1437;
—Polyhaloallyl, substituted, allyl rearrangement in, 303;
—Of 2-cyanoethyl ethers of acetylenic alcohols, to the corresponding methyl esters, 845.
Aldehydes, aliphatic, condensation with ferrocene (dicyclopentadienyliron), 243;
—Condensation with acetylene under pressure, in presence of potassium hydroxide powder, to form acetylenic alcohols, 979;
—Reaction with acetaldehyde dibutyl acetal (transacetalation), 365.
Alkanes, (C_6—C_{10}), chlorination in presence of nitrogen dioxide in the vapor and liquid phases, 583;
—Vapor phase nitration with nitrogen dioxide, possibility of primary radical formation in, 883.
Alkenes, reaction with deuterium atoms. Dependence of the extent of deuteration of methane on the concentration of deuterium atoms in the system, 511.
Alkylation. Effect of enolization on the ability of β-dicarbonyl compounds to undergo C-alkylation reactions, 197;
—low-temperature, of α and β-olefins with *tertiary* alkyl halides in presence of zinc chloride, 65;
—Of benzene, see benzene;
—Of 2-dialkylaminovinyl ketones, new synthesis of hydroxymethylene ketones, 687.
Alkyl halides, tertiary, for low-temperature alkylation of α- and β-olefins, in presence of zinc chloride, 65.
Alloys, aluminum — zinc, efficiency of protector blocks of, data on stationary electrode potentials, protective currents, anodic polarizabilities and stability in use, of alloys and pure metal, 1067;
—Nickel-chromium-tungsten-titanium-aluminium, of high strength properties, system in the region of nickel solid solutions, 907.
Allyl rearrangement, in some substituted polyhaloallyl alcohols, 303.
Alumina, effect of steam and compression treatments on the macrostructure and catalytic activity of, 803;
—Platinized, use in high-temperature reactions of decane in presence of hydrogen at high pressure, 337.
Aluminum, system with nickel-chromium-tungsten-titanium, in the region of nickel solid solutions and the preparation of alloys of high strength properties, 907;
—System with titanium, phase diagram for, study by thermal analysis, microstructure analysis, hardness and heat-stability determination, 787;
—And iron, investigation with the aid of labeled atoms, of the conditions required for their separation from zinc and cobalt, 1213;
—And iodine, reaction with hexaalkyldisiloxanes to form trialkyliodosilanes, 725;
—Organic compounds. Polyorganoaluminosiloxanes, preparation, cleavage, 79;
—Zinc alloys, see alloys.
Amides, 3-(acylamino)-4-ethyloctan, diastereoisomeric, action of hypobromite on, 483;
—Alkyl, of organic derivatives of phosphorus acids, preparation, properties, 953.
Amino acids. Decarboxylation of α-acylamino β-halo carboxylic acids, 871;
—Separation from ammonium chloride with aid of cation-exchange resins, 169;
— Some reactions of β-amino-1-naphthalenepropionic acid and β-methylamino-1-naphthalenepropionic acid, 577;
—α-Carboxy, anhydrides of, polymerization, to 2,5-piperazinediones, 755;

– Mercapto, reacions of. Preparation, properties, of α,β-disubstituted α-acylamino carboxylic acids, 853.
α-Amino acids, esters of, see esters.
β-Amino acids, reduction with lithium aluminum hydride, to corresponding amino alcohols, 573.
Ammonium chloride, systems with $CdCl_2$–H_2O, $NiCl_2$–H_2O, interphase partition in, 1469.
Analytical chemistry. Application of the iodoform reaction to the analysis of some vinyl compounds, 615;
– Determination of fluorine in silicates, 1355;
– Differential titration of tripeptides and piperazinediones in the polycondensation products from glycine ethyl ester, 631;
– Investigation with the aid of labeled atoms of the conditions required for the separation of zinc and cobalt from aluminum and iron, 1213;
– Isomerization of isopropenylcyclobutane on silica gel under conditions of chromatographic adsorptional analysis, 1459.
Anhydride, N-carboxyglycine, copolycondensation with glycine ethyl ester, 1543.
Anhydrides, maleic, citraconic, condensation with 2-methoxy-1,3-butadiene and with the methyl esters of fumaric and mesaconic acids, 1505.
Area, surface, of catalysts, application of the dynamic method of measuring adsorption of vapors to, the determination of, 1329.
Arylation, trans, of bibenzyl at various temperatures, 223;
– Trans, of bibenzyl, effect of catalyst concentration on, 229.
Atomization, heat of, of carbon, 1451.
Atoms, in organic compounds, attempt to set up a semiquantitative theory of mutual effects of, electronic charges of bonds and physical properties of molecules, 1475;
– Properties at superhigh pressures, thermodynamics, quantum-chemical and seismological data, 417;
– Semiquantitative theory of mutual effects of, in organic compounds. Electronic charges of bonds, electronegativities of atoms, and the heats of formation of saturated hydrocarbons, 1375.
Barium oxide, ternary system with CaO–SiO_2, phase diagram of, 651.
Benzene, alkylation with propene, efficiencies of various catalysts in, 1027;
– C^{14}-labeled, synthesis of, 1557;
– Condensation with 2-chlorovinyl ketones to form styryl ketones, 1225;
– Reactions with trichlorosilane and dichloromethylsilane, 637;
– System with stannic bromide, thermal analysis of, 911;
– System with mercury halides-SnI_4, electrical conductivities of, 507;
– Systems with SnI_4, – mercury halides, kinetics of evaporation of solvents from, 507;
– Vapors, heat of adsorption on carbon blacks, thermodynamics of the process and adsorption forces, 1339;
– And homologs, alkylation and dealkylation in presence of aluminosilactes, to form toluene, 1007.
– Isopropyl, homogeneous destructive hydrogenation of, under high pressures of hydrogen, 55;
– Propyl– and isopropyl, high-temperature reactions of, over a nickel-alumina catalyst in presence of hydrogen at high pressure, 43;
– 1,3,5-trinitro,derivatives dipole moments of, (2,4,6-trinitrotoluene, 2,4,6-trinitro-m-xylene,styphnic acid), 119.
Biochemistry. Kinetic method of applying labeled atoms in the investigation of complex chemical and biochemical processes. Rates of formation and transformation of acetaldehyde, carbon monoxide and carbon dioxide in the oxidation of propene, 397.
Bond,carbon – carbon, in compounds containing the triphenylmethyl group, scission of, absorption spectra, 299;
– Si-H, optical investigation of, and peculiarities of its chemical behavior in various compounds, 1269.
Boric acid, esterification in the presence of, synthesis of boric esters, 743.
Borines, aryldichloro, see boron organic compounds.
Boron organic compounds. Action of organic bases on chlorodiphenylborine, 1561;
– Action of phosphorus pentachloride on areneboronic esters. Synthesis of arenechloroboronic esters, 361;
– Actions of phosphorus pentachloride on dialkylborinic and alkaneboronic esters. Synthesis of dialkylchloroborines and alkanechloroboronic esters, 501;
– Action of phosphorus pentachloride on diarylborinic ester. Synthesis of diarylchloroborines, 359;
– Complex nature of salts of organoboron acids, 703;

– Preparation of isobutyl esters of benzeneboronic and diphenylborinic acids with the aid of phenyllithium, 311;
– Reaction between the ether complex of boron trifluoride and lithium hydride, preparation of pure diborane, 925;
– Synthesis and properties of diarylborinic acids, 441;
– Synthesis of aryldichloroborines, 1165.
1,3-Butadiene, 2-methoxy, condensation with maleic and citraconic anhydrides and with the methyl esters of fumaric and mesaconic acids, 1505.
1-Butene, hydrocondensation with carbon monoxide, 733.
2-Butene, catalytic hydrocondensation with carbon monoxide, 465; 889.
Butenes, 1–, 2–, interconversion of, under conditions of catalytic hydrocondensation of carbon monoxide with olefins, 457.
Cs^+ ions, see ions.
Cadmium chloride, system with $NH_4Cl–H_2O$, interphase partition in, 1469.
Calcium oxide, ternary system with $BaO–SiO_2$, phase diagram of, 651.
Carbazole, 9-vinyl, copolymerization with vinyl acetate and the properties of the copolymers, 217;
– 9-vinyl, copolymerization with vinyl esters, 79.
Carbon, heat of atomization of, 1451;
– Active, surface and sorption properties of. Effect of chemically adsorbed and chemisorbed oxygen on the absorption properties, with respect to water vapor, 1055.
Carbon dioxide, rate of formation and transformation in the oxidation of propene, 397.
Carbon monoxide, catalytic hydrocondensation with olefins (2-butene), 465;
– Catalytic hydrocondensation with olefins, interconversion of 1– and 2– butenes, 457;
– Hydrocondensation with olefins (1–butene), 733;
– Participation of 2-butene in the hydrocondensation reaction with, 889;
– Rate of formation and transformation in oxidation of propene, 397.
Carbon tetrachloride, reaction with vinyl ethers to form addition and polymeric products, 1263.
Carbonyl compounds, physical basis of the reactivity of, 1383.
Catalysis, All-Union conference on the application of isotopes in catalysis, 1315;
– Catalytic activity of silica gel treated with solutions of aluminum salts, 1207;
– Effect of steam and compression treatment on the macrostructure and catalytic activity of alumina, 803;
– Effect of the method of preparation and the presence of a carrier on the catalytic activity of chromic oxide in dehydrogenation and dehydration reactions, 1285;
– Electron-microscope investigations of Polish Sandomir silicas, 1195;
– Relation between the catalytic activity of binary compounds of group II metals with nonmetals and the positions of the elements in Mendeleev's periodic system. Catalytic decomposition of isopropyl alcohol over alkaline-earth oxides, 879.
Catalyst, nickel as, in the Kizhner decomposition of hydrazones, 623.
Catalysts, efficiencies of, in alkylation of benzene with propene, 1027;
– Measurement of surface areas of, by the dynamic method of adsorption of vapors, 1329;
– Aluminosilicate, cracking, coke formation on, composition, unsaturation of coke, 521;
– Mixed $MgO–Cr_2O_3$, determination of specific surfaces of the components of, 1551;
– Nickel, mechanism of deactivation by steam under pressure, 935;
– Nickel, zinc and chromium oxides, sulfides, selenides, as, for the decomposition of isopropyl alcohol, 587;
– Nickel, zinc and chromium oxides, sulfides and selenides as, in the reduction of nitrobenzene, activities of, and the selective hydrogenation of a diolefin into an olefin, 595;
– Nickelous oxide treated with steam under pressure, selective action of, 121.
Cathode processes, occurring in the electrodeposition of thorium from fused electrolytes, 1321.
Cellulose. Chemical changes produced in the cellulose macromolecule by oxidizing agents. Causes of the chemical instability of celluloses oxidized with nitrogen dioxide, 603;
– Oxidation by nitrogen dioxide, mechanism of, 343;
– Thermal decomposition in vacuum, influence of various factors, formation of levoglucosan, 1295;
– Cotton, oxidized, ion exchange on (Ni^{2+}, Fe^{3+}), 497.
Chain reactions, criteria for, identification of, using labeled atoms, 405.

Charges, electronic, of bonds and physical properties of molecules, attempt to set up a semi-quantiative theory of mutual effects of atoms in organic compounds, 1475.
Chemistry, in furtherance of continuing progress in the science of, 257.
Chlorination, of alkanes, in presence of nitrogen dioxide, 583;
– Of tetraethylsilane and chloro(ethyl)silanes, 1087.
Chlorine, action on unsaturated polychloro compounds in an acid medium, to form saturated polychloro hydrocarbons, 1229.
Chlorinolysis, of hexachloropropene and octachloro-1,3-pentadiene, 893.
Chloromethylation, of 2,5-dimethylthiophene, 487.
Chloroprene, copolymerization with vinyl ethers (isopropyl vinyl ether), mechanism of, 1137.
Chromic oxide, catalytic activity in dehydrogenation and dehydration reactions, effects of the method of preparation and presence of a carrier on, 1285.
Chromium, system with nickel-tungsten-titanium-aluminum, in the region of nickel solid solutions and alloys of high strength properties, 907.
Citraconic anhydride, see anhydrides.
Cobalt, and zinc, investigation with the aid of labeled atoms, of the conditions required for their separation from aluminum and iron, 1213.
Coke, formation on aluminosilicate cracking catalysts, composition, saturation, 521.
Colloids. Colloidal properties of polonium, comparison of results obtained by various methods of investigation, 771.
Condensation, of aliphatic nitro carboxylic esters (ethyl 3-hydroxy-2-nitrobutyrate, methyl 3-nitropropionate, methyl 4-nitrobutyrate), 875;
– Diene, of 1-vinyl-1-cyclohexene with maleic anhydride, stereochemistry of, 727;
– Poly, of 1,2-dichloroethane with tetralin, 107.
Conference, All-Union, on the application of isotopes in catalysis, held March 31st to April 5th, 1956, in Moscow, 1315;
– Chemical, in the German Federal Republic. Annual meeting of the German Society for the investigation of fats, 369;
– Hungarian chemical; held in Budapest, November, 1955, 643;
– Of Austrian and German chemists, held at Salzburg, April, 1956, 1464;
– On electrochemistry at the Polish Academy of Sciences, 253;
– Second joint scientific session of the Chemical Institutes of the Transcaucasian Academies of Sciences, 1183;
– Second, on methods of investigating the structure of highly dispersed and porous bodies, 1461;
– Third All-Union, on Physicochemical analysis, 127.
Coordination numbers, of Rb^+ and Cs^+ ions in aqueous solutions, 1449.
Corrosion, of metals, Effect of temperature on the limiting diffusion current and the thickness of the diffusion layer at copper, iron and amalgamated copper electrodes in stirred and unstirred solutions of sodium chloride and ferric chloride, 797;
– Of metals, effect of the temperature factor, 9.
Current, diffusion, and thickness of the diffusion layer, effect of temperature on, at copper, iron and amalgamated copper electrodes in stirred and unstirred solutions of sodium chloride and ferric chloride, 797.
Cyanoethylation, of acetylenic alcohols, with acrylonitrile, 191;
– Of trichlorosilane, 247.
Cyclic compounds, stereochemistry of, condensation of 2-methoxy-1,3-butadiene with maleic and citraconic anhydrides and with the methyl esters of fumaric and mesaconic acids, 1505;
– Stereochemistry of. Condensation of 1-vinyl-1-cyclohexene with methyl acrylate, 557;
– Stereochemistry of. Synthesis and stereochemistry of isomeric decahydro-1,2-naphthalenedicarboxylic acids, 1107.
Cyclobutane, isopropenyl, isomerization on silica gel under conditions of chromatographic adsorptional analysis, 1459;
– Isopropyl, isopropenyl, catalytic hydrogenation of, 1309;
– Cis-1,3,5-trimethyl,preparation, physical properties, 1161;
Cyclohexanes, sila, see silicon organic compounds.
Cyclohexene, 1- (1-acetoxyvinyl), condensation with methyl acrylate, isolation of isomeric products, 1241.
1-Cyclohexene, 1-vinyl, condensation with methyl acrylate, stereochemistry of the products, 557;
– 1-Vinyl, diene condensation with maleic anhydride, stereochemistry of, 727.
Cyclopentadiene, condensation with acetylene to form bicyclo [2,2,1] hepta-2,5-diene, 753;

– Conversion to cyclopentene, 1173;
–Hydrogenation of, in binary mixtures with other unsaturated hydrocarbons in presence of Raney nickel, 1347;
– Cyclopentadiene, hydrogenation over Raney nickel and platinum black, effect of pyridine on the rate and selectivity of, 1547;
– Possibility of formation from heterocyclic compounds containing five carbon atoms, (tetrahydro-2-methylfuran, tetrahydro-2-methylthiophene, 2-methylpyrrolidine, piperidine, in presence of titania-alumina catalyst), 205;
– Stepwise character of the hydrogenation of the double bonds, over Raney nickel, 1199.
Cyclopentanes, silicyl, see silicon organic compounds.
Cyclopentene, preparation from cyclopentadiene, properties, 1173.
Cyclopropane, isopropenyl, hydrogenation in presence of platinum black to form a mixture of isopropylcyclopropane and 2-methylpentane, 1119;
– Isopropenyl, hydrogenation in presence of palladium black, to 2-methylpentane, 35;
– Isopropyl, isopropenyl, catalytic vapor-phase hydrogenation, 1431.
Dealkylation, of benzene, see bezene.
Decane, high-temperature reactions over platinized alumina in presence of hydrogen at high pressure, 337.
Decarboxylation of α-acylamino β-halo-carboxylic acids (N-benzoyl-3-chloro-2-hydroxyvaline), 871.
Dehydration (isopropyl alcohol, formic acid), catalytic activity of chromic oxide on, effect of, method of preparation and presence of a carrier on, 1285.
Dehydration reaction, (of alcohols) in presence of zinc halides, mechanism of, 1511.
Dehydrogenation (methylcyclohexane, isopropyl alcohol, formic acid), catalytic activity of chromic oxide on, effect of method of preparation and presence of a carrier, 1285;
– Of isopropyl and ethyl alcohols over manganous oxide, kinetics of, 1437.
Demethylation, of o-xylene over aluminosilicates optimum conditions for, 1421.
Densities, of aqueous uranyl nitrate solutions and the apparent molar volumes of uranyl nitrate, 661.
Deuterium atoms, reaction with alkenes. Dependence of the extent of deuteration of methane on the concentration of deuterium atoms in the system, 511.
Diazo compounds, mechanism of reactions with metals to form organometallic compounds (Nesmeyanov reaction, Waters reaction), 983.
Diazo ketones, see ketones.
Dibenzyl, effect of catalyst concentration on the transarylation of, 229;
– Transarylation at various temperatures, in presence of aluminum chloride, 223.
Dichlorides, of 2-(alkylthio) vinylphosphonic acid preparation, properties, 21.
2,5-Diene, bicyclo [2,2,1] hepta-, preparation by condensation of cyclopentadiene with acetylene, 753.
Dienols, irreversible systems with organic hydroperoxides and salts of metals of variable valence, mechanism of action of, 1521.
Diffusion current, see current.
Dipole moments, of alkyl 2-dialkylaminovinyl ketones, 245;
– Of derivatives of 1,3,5-trinitrobenzene, (2,4,6-trinitrotoluene, 2,4,6-trinitro-m-xylene, styphnic acid), 119.
Distances, interatomic, and π-electron density determination of, confirmation of hypothesis, 527.
Doisynolic acid, analogs of, not containing a B ring, preparation, properties, 1493.
Dyestuffs chemistry. Scission of the carbon-carbon bond in compounds containing the triphenylmethyl group, 299.
Electrochemistry. Cathode processes occurring in the electrodeposition of thorium from fused electrolytes, 1321;
– Effect of temperature on the diffusion current and the thickness of the diffusion layer, 797;
– Effect of the temperature factor on the rate of corrosion of metals in electrolytes, 9;
– Efficiency of protector blocks of aluminum-zinc alloys, 1065.
π-Electron density, and interatomic distances, determination of, confirmation of hypothesis, 527.
Electronic charges, see charges.
Enolization, effect on the ability of β-dicarbonyl compounds to undergo Michael and C-alkylation reactions, 197.
Epoxides, α-keto, and their reactions, geometric isomerism of the α-keto diepoxide series, 1499;
– From cyclic ketones, preparation, properties, reactions, 1415.
Erratum, i. (no. 10);
– Table omitted from article, (pages 1305-1307), i (No. 11).
Ester, glycine ethyl, copolycondensation with N-carboxyglycine anhydride, 1543;

– Glycine ethyl, kinetics and chemistry of the polycondensation of, 993;
– Glycine ethyl, polycondensation products from, differential titration of tripeptides and piperazinediones in, 631.
Esters, aliphatic, nitro carboxylic, (ethyl 3-hydroxy-2-nitrobutyrate, methyl 3-nitropropionate, methyl 4-nitrobutyrate, triethyl-1,2-ethanetricarboxylate), condensation reactions of, 875;
– Alkanechloroboronic synthesis, properties, 501;
– α-Amino acid, copolycondensation of glycine ethyl ester and N-carboxyglycine anhydride, 1543;
– Arenecboronic, action of phosphorus pentachloride, synthesis of arenechloroboronic esters, 361;
– Boric acid, preparation, properties, 743;
– Butyl oleate, dibutylphthalate, reaction with active nitrogen, 541;
– Chloroformic, use in acylation of aminoalkylphosphonic and -phosphonothionic acids, 315;
– Di-, of 2-indenylphosphonic acid, preparation, properties, 13;
– Dialkylborinic, alkaneboronic, action of phosphorouspentachloride, 501;
– Diarylborinic, action of phosphorus pentachloride, synthesis of diarylchloroborines, 359;
– 1-Hydroxyalkylphosphonic, acylderivatives of, preparation, properties, 959;
– Isobutyl, of benzeneboronic and diphenylborinic acids, preparation with the aid of phenyllithium, 311;
– 1-Isocyanatoalkylphosphonic, preparation, properties, 695;
– Methyl, of fumaric and mesaconic acids, condensation with 2-methoxy-1,3-butadiene, 1505;
– o-Phenylene, of pyrophosphorus acid, preparation, properties, 691;
– Phosphonic acid, see phosphonic acids;
– Vinyl, copolymerization with 9-vinylcarbazole, 79.
Ethane, kinetics of oxidation of, to acetic acid, in presence of hydrogen bromide, 669;
– 1,2-Dichloro, polycondensation with tetralin, 107.
Ether, isopropyl vinyl, copolymerization with chloroprene, mechanism of, 1137.
Ethers, 2-carboxyethyl, of acetylenic alcohols, see acetylene derivatives;
– 2-Cyanoethyl, of acetylenic alcohols, alcoholysis of, to the corresponding methyl esters, 845;
– 2-Cyanoethyl, of acetylenic alcohols containing aromatic substituents, preparation, properties, reactions, 1410;
– Vinyl, addition of mercury salts. Preparation, properties, of mercurated acylals, 173;
– Vinyl, copolymerization with chloroprene, mechanism of, 1137.
– Vinyl, formation of low-molecular weight polymers from, in presence of benzoyl peroxide, 351;
– Vinyl, of 3-(trimethylsilyl)- and 3-(diethylmethylsilyl)-1-propanol, synthesis, properties, reactions, 1535;
– Vinyl, reaction with carbon tetrachloride, in presence of benzoyl peroxide, with formation of addition and polymeric products, 1263.
Ethyl alcohol, see alcohols.
Ethylene, catalytic oxidation over silver, mechanism of, 271;
– 1,2-bistrichlorosilyl, cis-trans isomerism of, 1457;
– Tetrachloro, thermal reactions at superhigh pressures, 739.
Ethylenes, chloro-, chlorotrifluoro-, tetrafluoro-, addition of CH_3SiHCl_2 and $C_2H_5SiHCl_2$, 633.
Ethylenimine, reaction with dialkyl phosphorochloridates, 535.
Ferrocene(dicyclopentadienyliron), condensation with aldehydes, 243.
Ferrocene compounds, Breakdown of the ferrocene nucleus by hydrogenation and the action of halogens, 749.
Fibers, artificial (Capron). Hydrogen bonding in ε-caprolactam and polycaprolactam, 87;
– Artificial (Capron); mixed polyamides containing certain amino-acid residues, 93;
– Artificial (Capron). Polyamides containing ether linkages in their macromolecular chains, preparation, properties, 97;
– Artificial (Capron); three-component mixed polyamides having amino-acid components, preparation, properties, 101.
Flame, propagation in mixtures of hydrogen and oxides of nitrogen, concentration limits for, 779.
Fluorides, di, alkylene, use in organomagnesium synthesis, 503;
– Tertiary alkyl, use in organomagnesium synthesis, 503.
Fluorine, review of methods of determination in silicates, 1355.
Fluoroolefins, see olefins.
Fluosilicate, benzenediazonium, heterolytic decomposition of, 425.
Fumaric, acid, methyl ester, see esters.
Furan compounds, Opening of the tetrahydrofuran ring under the action of aluminum halides, 761.

Furan, tetrahydro, see furan compounds.
Gas mixture, possibility of detonation in conical tubes, 409.
Germanium organic compounds, unsaturated, preparation, properties, 1169.
Glass chemistry. Structure of sodium borosilicate glasses in its relation to the phenomenon of opalescence. Dependence of the structure on the duration of heating at constant temperature, 277.
Glucoside, methyl, oxidation with nitrogen dioxide, 473.
Glycine ethyl ester, see ester.
Haloalkylsilanes, see silicon organic compounds.
Halogens, conjugated addition to perfluoroolefins, 863.
Heat of adsorption, see adsorption.
Heat of atomization, see atomization.
Heat of formation, of saturated hydrocarbons, 1375.
1,3,5-Hexatrienes, 1,5-diaryl, see polyenic compounds.
High polymer chemistry. Chemical changes produced in the cellulose macromolecule by oxidizing agents. Oxidation of cellulose by nitrogen dioxide, 343;
– Differential titration of tripeptides and piperazinediones in the polycondensation products from glycine ethyl ester, 631;
– Formation of low-molecular-weight polymers of vinyl ethers in presence of benzoyl peroxide, 351;

– Mechanism of the catalytic polymerization of propene under pressure, 1153;
– Oligomerization. Reaction of some vinyl ethers with carbon tetrachloride, 1263;
– Oxidation-reduction systems for the initiation of free-radical processes reversible systems in which organic hydroperoxides, dienols and salts of metals of variable valence take part, 1521;
– Peculiar features of the copolymerization of chloroprene with vinyl ethers, 1137;
– Polymerization and copolymerization of alkenylsilanes under high pressure, 999;
– Polymerization and copolymerization of N-vinyl compounds. Copolymerization of 9-vinylcarbazole with vinyl esters, 79;
– Polymerization and copolymerization of N-vinyl compounds. Some characteristics of the copolymerization of vinyl acetate with 9-vinylcarbazole and the properties of the copolymers, 217;
– Polyorganostanno- and polyorganotitanosiloxanes, 817;
– Stereochemistry of cyclic compounds. Condensation of 1- (1-acetoxyvinyl) cyclohexene with methyl acrylate, 1241.
Hofmann reaction, new data on. Action of hypobromite on diastereoisomeric 3- (acylamino)-4-ethyloctanamides, 483.
Hydration reaction, in presence of zinc halides, (olefins), mechanism of, 1511.
Hydrazones, use of a nickel catalyst, in the Kizhner decomposition of, 623.
Hydrocarbons (benzene, naphthalene), action of active nitrogen, 707;
– Saturated, heats of formation of electronic charges of bonds, electronegativities of, 1375;
– Saturated, unsaturated reaction with active nitrogen, 541;
– Unsaturated, specificity of the catalytic oxidation of, 271.
Hydrogen, mixtures with oxides of nitrogen, concentration limits for flame progagation in, 779;
– Possible mechanism of catalytic oxidation of, on metals, 139.
Hydrogenation, catalytic, of isopropyl and isopropenyl-cyclobutane, 1309;
– Catalytic, vapor-phase, of isopropylcyclopropane and isopropenylcyclopropane, 1431;
– Destructive, of 2-methylthiophene with hydrogen at high pressure, 249;
– Homogeneous destructive, of isopropylbenzene under high pressures of hydrogen, 55;
– Of cyclopentadiene in binary mixtures with other unsaturated hydrocarbons in presence of Raney nickel, 1347;

– Of diphenylacetylene and cyclopentadiene over Raney nickel and platinum black, effect of pyridine on the rate and selectivity of, 1547;
– Of isopropenylcyclopropane, in presence of platinum black, 1119;
– Of isopropenylcyclopropane, in presence of palladium black, to 2-methylpentane, 35;
– Stepwise, of the double bonds of cyclopentadiene over Raney nickel, 1199.
Hydrogen disulfide, role in the vulcanization process, 1179.
Hydrogen fluoride, reaction with diazo ketones, 363.
Hydrogen iodide, reaction with trialkylsilanes, to form trialkyliodosilanes, properties of the products, 827.
Hydrogen peroxide, system with LiOH-H_2O, characterization of the solid phases by thermal analysis, 283.
Hydroperoxides, organic, reversible systems with dienols and salts of metals of variable valence, mechanism of action of, 1521.
Hydroxy compounds, of low molecular weight (isopropyl alcohol, ethylene glycol, 1,2-propanediol, methyl glucoside), oxidation with nitrogen dioxide, 473.
Hypobromite, action on diasteroisomeric 3-(acylamino)-4-ethyloctanamides, 483.
Indene derivatives. Diesters of 2-indenylphosphonic acid, preparation, properties, 13.
Insecticides, alkylamides of organic derivatives of phosphorus acids, as, 953.
Iodine, reaction with trialkylsilanes, to form trialkyliodosilanes, properties of the products, 823;
– And aluminum, reaction with hexaalkyldisiloxanes, to form trialkyliodosilanes, 725.
Ion exchange (Ni^{2+}, Fe^{3+}), on cotton and oxidized celluloses, 497.
Ion exchange resins. Separation of amino carboxylic acids from ammonium chloride with the aid of cation– exchange resins, 169.
Ions, Rb^+, Cs^+, in aqueous solutions, coordination numbers of, 1449.
Iron, and aluminum, investigation with the aid of labeled atoms, of the conditions required for their separation from zinc and cobalt, 1213;
– Dicyclopentadienyl, see ferrocene;
– Ores, see ores.
Isobutene, perfluoro, reactions with nucleophilic reagents (alcohols, thiols, amines), 1387.
Isodurene homologs (ethyl-, propyl-, allylmesitylene), preparation, properties, 1021.
Isomerism, cis-trans, of 1,2-bistrichlorosilylethylene, spectrographic detection of, 1457;
– Geometric, in the α-keto diepoxide series, 1499.
Isomerization of isopropenylcyclobutane on silica gel under the conditons of chromatographic adsorptional analysis, 1459;
– Of o-xylene, optimum conditions for, 1421.
Isopropyl alcohol, see alcohols.
Isotope chemistry. Criteria for chain reactions, 405;
– Kinetic method of applying labeled atoms in the investigation of complex chemical and biochemical processes. Rates of formation and transformation of acetaldehyde, carbon monoxide and carbon dioxide in the oxidation of propene, 397;
– Reaction of deuterium atoms with alkenes. Dependence of the extent of deuteration of methane on the concentration of deuterium atoms in the system, 511.
Kerosene fraction, of Tuimazin (Devonian) petroleum, compositon of naphthene part of, 1127.
Ketones, alicyclic, α, β-unsaturated, conversion to the corresponding α-keto epoxides, properties and reactions of the latter, 1415;
– Alkenyl 2-chlorovinyl, synthesis, properties, reaction with 2-naphthol in presence of ferric chloride to form chloroferrates, 1069;
– Alkyl 2-dialkylaminovinyl, dipole moments of, 245;
– 2-aminovinyl, Synthesis of ketones of the pyridine series, 165;
– Aromatic, aliphatic-aromatic, condensation with acetylene under pressure to form the corresponding tertiary acetylenic alcohols, 1403;
– 2-Chlorovinyl, condensation with benzene and its homologs, to form styryl ketones, 1225;
– Condensation with acetylene under pressure, in presence of potassium hydroxide powder, to form acetylenic alcohols, 979;
– Cyclic saturated, condensation with α, β- unsaturated cyclic ketones, 31;
– 2-Dialkylaminovinyl, alkylation of, new synthesis of hydroxymethylene ketones, 687;
– Diazo, reactions with hydrogen fluorides, 363;
– Hydroxymethylene, new synthesis of, from 2-dialkylaminovinyl ketones, 687;
– Reaction with acetaldehyde dibutyl acetal (transacetalation), 365;
– Unsaturated, reaction with organolithium compounds to form 1,3,5-hexatrienes, 1095;
– α, β-unsaturated, condensation with cyclic saturated ketones, 31.

Kizhner decomposition, of hydrazones, use of nickel as catalyst, 623.
Knunyants, Ivan Lyudvigovich, fifteith birthday greetings to, 769.
Lactones, of 1,2,3,5,6,7,8,8a-octahydro-1,2,-naphthalenedicarboxylic acids, stereochemistry of, 971.
Lignin, isolated, nitration with dilute nitric acid at the boil, 239.
Lithium aluminum hydride, as reducing agent for β-amino acids, 573.
Lithium hydride, reaction with ether complex of boron trifluoride, preparation of pure diborane, 925.
Lithium hydroxide, system with H_2O_2-H_2O, characterization of the solid phases by thermal analysis, 283.
Lithium organic compounds. Preparation of isobutyl esters of benzeneboronic and diphenylborinic acids with the aid of, 311.
Maleic anhydride, diene condensation with 1-vinyl-1-cyclohexene, stereochemistry of, 727;
– See also anhydrides.
Medicinal chemistry. Acetylene derivatives. Synthesis of 2-carboxyethyl ethers of acetylene alcohols and of their acid chlorides and amides, 1247;
– Acylation of aminoalkyl-phosphonic and -phosphonothionic acids with chloroformic esters, 315;
– Decarboxylation of α-acylamino β-halo carboxylic acids, 871;
– Differential titration of tripeptides and piperazinediones in the polycondensation products from glycine ethyl ester, 631;
– Investigation of hydrogen bonding in α-aminonicotine by the method of comparing infrared absorption spectra, 323;
– Kinetics and chemistry of the polycondensation esters of α-amino acids. Copolycondensation of glycine ethyl ester and N-carboxyglycine anhydride, 1543;
– Organophosphorus ethylenimine derivatives. Reaction of ethylenimine with phosphorochloridates, 535;
– Preparation and reactions of some derivatives of 3-ureidononanoic acid, 319;
– Reactions of mercapto amino acids. Communication 11. α, β- Disubstituted α-acylamino carboxylic acids, 853;
– Reduction of β-amino acids with lithium aluminum hydride, 573;
– Some peculiar features of the polymerization of anhydrides of α-carboxyamino acids, 755;
– Some reactions of β-amino-1-naphthalenepropionic acid and β-methylamino-1-naphthalenepropionic acid, 577;
– Synthesis of cancerolytic peptides, 1455;
– Synthesis of polycyclic compounds related to steroids. Condensation of cyclic saturated ketones with α, β- unsaturated cyclic ketones, 31;
– Synthesis of steroid compounds and related substances. Analogs of doisynolic acid not containing a B ring, 1493;
– Synthesis of steroid compounds and related substances. Synthesis of steroid analogs not containing a B ring, 567.
Meeting annual, of the Division of Chemical Sciences of the Academy of Sciences of the USSR, held on 31.1. and 1.2.56, 763;
– General, of the Division of Chemical Sciences of the Academy of Sciences of the USSR, on April 25 and 26, 1956, 899.
Mercapto amino acids, see amino acids, mercapto.
Mercury halides, systems with benzene, kinetics of evaporation of solvent from, 507;
– Systems with SnI_4-benzene, -nitrobenzene, electrical conductivities of, 507.
Mercury organic compounds. Exchange reactions of stereoisomeric derivatives of stilbene, 157;
– Reaction of bases with unsaturated compounds, (hydrocarbons, vinyl ethers, ketene diethyl acetal), 25.
Mercury salts, addition to vinyl ethers. Preparation, properties, of mercurated acylals, 173.
Mesaconic acid, methyl ester, see esters.
Mesitylene, ethyl-, propyl-, allyl-, preparation, properties, 1021.
Metallurgical chemistry. "Complex" reduction of multimetal iron and nickel ores as a basis for new methods for their chemical treatment, 1187;
– Effect of temperature on the diffusion current and the thickness of the diffusion layer, 797;
– Part of the five-component system nickel-chromium-tungsten-titanium-aluminum, 907;
– Phase diagram of the binary system titanium-aluminum, 787;
– Principles underlying new methods for the chemical treatment of complex iron and nickel ores, 1047.
Metals, corrosion in electrolytes, effect of the temperature factor, 9;
– Reactions with diazo compounds to form organometallic compounds (Nesmeyanov reaction, Waters reaction), 963;

– Unusual valencies of, 131.
Methane, dependence of extent of deuteration of, on the concentration of deuterium atoms in the system, 511.
Methanol, di-2-thienyl, see thiophene compounds.
Methyl acrylate, condensation with 1-(1-acetoxyvinyl) cyclohexene, isolation of isomeric products, 1241;
– Condensation with 1-vinyl-1-cyclohexene, stereochemistry of the products, 557.
Methylation, chloro, of toluene, to give a mixture of α-chloro-o-xylene and α-chloro-p-xylene, influence of conditions, 1529.
Methyl methacrylate, copolymerization with alkenylsilanes under high pressure, 999.
Michael reaction, effect of enolization on the ability of β-dicarbonyl compounds to undergo Michael reaction, 197.
Mineralogical chemistry. Liquation in the system ZrO_2-SiO_2, 153.
Naphthalene compounds. Some reactions of β-amino-1-naphthalenepropionic acid and β-methylamino-1-naphthalenepropionic acid, 577;
– Stereochemistry of 1,2,3,5,6,7,8,8a-octahydro-1,2-naphthalenedicarboxylic acids, 835;
– Synthesis and reactions of aliphatic-aromatic silanediols, 985;
– Synthesis and stereochemistry of isomeric decahydro-1,2-naphthalenedicarboxylic acids, 1107.
Naphthene, from kerosene fraction of Tuimazin (Devonian) petroleum, composition of, 1127.
Naphthenes, Raman spectra of, 1147.
Nazarov, Ivan Nikolaevich, fiftieth birthday greetings to, 770.
Nickel, system with chromium-tungsten-titanium-aluminum, in the region of nickel solid solutions, and the preparation of high strength alloys, 907;
– Catalysts, see catalysts;
– Chloride, system with NH_4Cl-H_2O, interphase partition in, 1469;
– Ores, see ores.
Nickelous oxide catalyst, see catalysts.
Nicotine, α-amino, investigation of hydrogen bonding in, by the method of comparing infrared absorption spectra, 323.
Nitration, vapor-phase, of alkanes with nitrogen dioxide, possibility of primary radical formation in, 883.
Nitrobenzene, nickel, zinc and chromium oxides, sulfides and selenides, as catalysts for the reduction of, 595;
– Systems with mercury halides- SnI_4, electrical conductivities of, 507.
Nitro carboxylic esters, see esters.
Nitrogen, active, action on organic substances, 541; 707.
Nitrogen dioxide, as oxidizing agent for cellulose, 343;
– As oxidizing agent for hydroxy compounds of low molecular weight (isopropyl alcohol, ethylene glycol, 1,2-propanediol and methyl glucoside), 473;
– Causes of the chemical instability of celluloses after oxidation with, 603;
– Chlorination of alkanes in presence of, 583.
Nomenclature. Report of the Chemical Nomenclature Commission of the Division of Chemical Sciences of the Academy of Sciences of the USSR, 903.
Octane, 2-cyclopentyl, synthesis, properties, 1297.
Olefin, di-, selective hydrogenation of, to an olefin, nickel, zinc and chromium oxides, sulfides and selenides as catalysts for, 595.
Olefins, catalytic hydrocondensation of carbon monoxide with, interconversion of 1- and 2-butenes, 457;
– α- and β, low-temperature alkylation with tertiary alkyl halides in presence of zinc chloride, 65;
– (1-butene), hydrocondensation with carbon monoxide, 733;
– (2-butene), catalytic hydrocondensation with carbon monoxide, 465;
– (2-butene), catalytic hydrocondensation with carbon monoxide, 889;
– Fluoro, reactions of perfluoroisobutene and perfluoropropene with nucleophilic reagents, (alcohols, thiols, amines), 1387;
– Perfluoro, addition reactions of. Conjugated additon of halogens, (bromine). in glacial acetic acid, to form acetic esters of β-bromo-α, α-difluoro alcohols, and in water, to form bromohydrin, 863.
Opalescence, and its relationship to the structure of sodium borosilicate glasses, dependence of structure on the duration of heating at constant temperature, 277.
Ores, complex iron and nickel, principles underlying new methods for the chemical treatment of, 1047;
– Iron, nickel, "complex" reduction of, as basis for new methods of chemical treatment, 1187.
Organic compounds. Attempt to set up a semi-quantitative theory of mutual effects of atoms in electronic charges of bonds, electronega-

tivities of atoms, and heat of formation of saturated hydrocarbons, 1375;
– Attempt to set up a semiquantitative theory of mutual effects of atoms in, electronic charges of bonds and physical properties of molecules, 1475.
Organometallic compounds, mechanism of formation from diazo compounds and metals, (Nesmeyanov reaction, Waters reaction), 963.
Oxidation, catalytic, of hydrogen on metals possible mechanism of, 139;
– Catalytic, of unsaturated hydrocarbons, specificity of, 271;
– Of acetaldehyde by peroxyacetic acid, effect of solvents on the rate of, from the point of view of intermolecular hydrogen bonding, 391;
– Oxidation, of acetaldehyde by peroxyacetic acid, spectroscopic study of the intermediate product and intermediate stage of reaction, 385;
– of acetaldehyde with peroxyacetic acid, kinetics of, 375;
– Of cellulose by nitrogen dioxide, mechanism of, 343;
– Of celluloses with nitrogen dioxide, causes of chemical instability of products, 603;
– Of ethane to acetic acid, kinetics of, in presence of hydrogen bromide, 669;
– Of hydroxy compounds of low molecular weight, (isopropyl alcohol, ethylene glycol, 1,2-propanediol and methyl glucoside) with nitrogen dioxide, 473.
Oxidation potentials, of organic sulfur compounds (thiols, sulfides, disulfides, thiophenes), 125.
Oxides, alkaline, earth, as catalysts for the decomposition of isopropyl alcohol, 679;
– Nickel, zinc, chromium, relative activities of, in the catalytic decomposition of isopropyl alcohol, 587;
– Nitrogen, mixtures with hydrogen, concentration limits for flame propagation in, 779;
– Of nickel, zinc, chromium, as catalysts for the reduction of nitrobenzene and the selective hydrogenation of a diolefin into an olefin, 595.
1,3-Pentadiene, octachloro, mechanism of the thermal decomposition and chlorinolysis of, 893.
Peptides, cancerolytic, containing a bis-2-chloroethylamino group, preparation, 1455;
– Tri, determination in polycondensation products of glycine ethyl ester, 631.
Perfluoroolefins, see olefins.
Petroleum chemistry. Alkylation and dealkylation of benzene and its homologs in presence of aluminosilicates, 1007;
– Catalytic activity and acidity of silica gel treated with aluminum salts, 1207;
– Composition of the thiophene-group component of the gaseous products of the thermal decomposition of Kashpir shales, 327;
– Contact-catalysis refining of Tuimazin gasoline, 211;
– Demethylation and isomerization of o-xylene over aluminosilicates, 1421;
– Efficiencies of various catalysts in the alkylation of benzene with propene, 1027;
– Investigation of the composition of the naphthene part of the kerosene fraction of Tuimazin (Devonian) petroleum, 1127;
– Primary radical formation in the vapor-phase nitration of alkanes with nitrogen dioxide, 883;
– Synthesis of 2-cyclopentyloctane and 5,5-dimethylundecane, 1297;
– Thermal transformations of piperylene at various pressures, 1277.
Phosphites, alkyl and aryl propylene, synthesis, addition reactions with sulfur, selenium and cuprous halides, 179.
Phosphonic acids, unsaturated, derivatives of. 2-chloro-3-butenyl- and 1,3-butadienyl-phosphonic esters, preparation, properties, 943;
– Unsaturated, derivatives of. 2-Chloro-3-methyl-3-butenyl- and 3-methyl-1,3-butadienyl-phosphonic esters, preparation, properties, 947.
Phosphorimidates, phenyl, trialkyl, see phosphorus organic compounds.
Phosphorus organic compounds. Acylation of aminoalkyl-phosphonic and -phosphonothionic acids with chloroformic esters, 315;
– Acyl derivatives of 1-hydroxyalkylphosphonic esters, 959;
– Alkylamides of organic derivatives of phosphorus acids, preparation, properties, 953;
– Derivatives of 1-aminoalkylphosphonic acids. 1-Isocyanatoalkylphosphonic esters and their reactions, 695;
– Derivatives of unsaturated phosphonic acids. 2-(alkylthio)- vinylphosphonic dichlorides and their derivatives, 21;
– Diesters of 2-inenylphosphonic acid, preparation, properties, 13;
– Ethylenimine derivatives. Reaction of ethylenimine with dialkyl phosphorochloridates, 535;
– O,O- and O,S-dialkyl alkylphosphonothioates, preparation, properties, 185;

– o-Phenylene esters of pyrophosphorus acid, 691;
– Properties and reactions of alkyl and aryl propylene phosphites. Addition reactions, 179;
– Reaction of O,O-dialkyl hydrogen phosphorodithioates with vinyl sulfides, 433;
– Structure of, 429;
– Trialkyl phenylphosphorimidates, synthesis by reaction of trialkyl phosphites with phenyl azide, properties, reactions, 809.
Piperazinediones, determination in polycondensation products from glycine ethyl ester, 631.
Piperylene, thermal transformations at 450-550° at elevated pressure, 1277.
Polonium, colloidal properties of, comparison of results obtained by various methods of investigation, 771.
Polyenic compounds containing heterocyclic substituents (quinoline, pyridine), preparation, reactions, 1489;
– Synthesis of 1,5-diaryl-1,3,5-hexatrienes, 1095.
Polymerization, catalytic, of propene, under pressure, 1153;
– co- of vinyl esters with 9-vinylcarbazole, 79;
– Free-radical and copolymerization of 2-butoxyethyl vinyl sulfide, 1257;
– Of anhydrides of α-carboxyamino acids, to 2,5-piperazinediones, mechanism of, 755.
1-Propanol, 3-(trimethylsilyl)-, 3-(diethylmethylsilyl)-, vinyl ethers of, synthesis properties, reactions, 1535.
Propene, for alkylation of benzene, efficiencies of various catalysts, 1027
– Mechanism of catalytic polymerization under pressure, 1153;
– Rates of formation and transformation of acetaldehyde, carbon monoxide and carbon dioxide in the oxidation of, 397;
– Hexachloro, mechanism of the thermal decompositon and chlorinolysis of, 893;
– Perfluoro, reactions with nucleophilic reagents (alcohols, thiols, amines), 1387.
Propylene oxide, reaction with alkyl- and arylchlorosilanes, 639.
Pyridine, effect on the rate and selectivity of hydrogenation of diphenylacetylene and cyclopentadiene over Raney nickel and platinum black, 1547.
Pyridine compounds. Infrared absorption spectra of α-aminopyridine and α-pyridonimine, 113;
– Polyenic compounds containing heterocyclic substituents, preparation, reactions, 1489;
– Synthesis, properties, of ketones of the pyridine series, 165.
Quartz, adsorption of vapors on, 3.
Quinoline compounds. Polyenic compounds containing heterocyclic substituents, preparation, reactions, 1489.
Radical formation, primary, possibility of in the vapor-phase nitration of alkanes with nitrogen dioxide, 883.
Radiochemistry. All-Union conference on the application of isotopes on catalysis, 1315;
– Colloidal properties of polonium, 771;
– Investigation with the aid of labeled atoms of the conditions required for the separation of zinc and cobalt from aluminum and iron, 1213.
Reactions, rapid, nonionic, metathetic, in a nonaqueous medium, 507.
Resins, cation-exchange, use in the separation of amino carboxylic acids from ammonium chloride, 169.
Rubber chemistry. Role of hydrogen disulfide in the vulcanization process, 1179.
Rb^+ ions, see ions.
Salts, aluminum, as activators for silica gel, 1207;
– Of metals with variable valence irreversible systems with organic hydroperoxides and dienols, mechanism of, action of, 1521.
Selenides, nickel, zinc, chromium, as catalysts for the reduction of nitrobenzene and the selective hydrogenation of a diolefin into an olefin, 595;
– Nickel, zinc, chromium, relative activities of, in the catalytic decomposition of isopropyl alcohol, 587.
Semenov, Nikolai Nikolaevich, 60th birthday of 373.
Shales, Kashpir, composition of the thiophene-group component of the gaseous products of the thermal decomposition of, 327.
Silanes, see silicon organic compounds;

INVESTIGATION OF THE ADSORPTION OF VAPORS ON QUARTZ

COMMUNICATION 1. METHOD OF INVESTIGATING ADSORPTION ISOTHERMS

A. I. Sarakhov

In the development of the theory of adsorption, the investigation of adsorption on nonporous adsorbents occupies a particularly important place, since it enables us to reach certain conclusions regarding the interactions of adsorbed molecules among themselves and with the adsorbent surface. In this connection great interest is presented by the study of adsorption on nonporous crystalline adsorbents having a comparatively homogeneous surface of known extent and similar to the surface of industrial adsorbents in chemical composition. However, very few such investigations have been described, a fact that is to be explained by the great difficulties met in the measurement of adsorption on such adsorbents. The specific surfaces of nonporous adsorbents are hundreds of times less than those of the usual adsorbents, so that the sensitivity of the methods used for the investigation of nonporous adsorbents must be hundreds of times as high as that of the usual methods.

In the main, three methods are used at present for the measurement of the adsorption of gases and vapors on solid adsorbents: the volumetric method, the gravimetric method, and the method, recently introduced, of independent weighing [1]. In the general case it is difficult to decide which of these methods is the best, for their accuracy is appreciably dependent on the character of the systems investigated and none of them is altogether universal. However, for the study of the adsorption of vapors of substances of low vapor pressure on nonporous adsorbents the best method would be the gravimetric method if its accuracy could be increased to that of the independent-weighing method or to the highest accuracy that can be obtained in volumetric methods. This could be done by increasing the sensitivity of the balance.

The low accuracy of the gravimetric method is not explicable in general by the low sensitivity of the balance used for the adsorption measurements, but must be attributed to the fact that in the gravimetric method it is necessary to weigh the adsorbed substance together with the adsorbent itself, which is very much heavier than adsorbed substance and forms an undesirable ballast in the weighing. For adsorption on nonporous adsorbents the ratio of the weights of adsorbent and adsorbed substance may be 1000 : 1 or higher for medium values of adsorption. If it is required that the accuracy of the method shall not be lower than that of other modern methods, the relative sensitivity of the balance—i.e. the ratio of absolute sensitivity to maximum load—must be about $1 \cdot 10^{-7}$. It should be noted that the relative sensitivity of the sorption balance generally used is about $1 \cdot 10^{-4}$ [1].

In general, balances having a relative sensitivity of $1 \cdot 10^{-7}$ are not rare, for as early as 1895 Mendeleev [2] worked with a balance of sensitivity $1 \cdot 10^{-9}$, and balances of sensitivity $1 \cdot 10^{-9}$ or thereabouts are now to be found in many laboratories. Unfortunately, the specificity of adsorption measurements completely excludes the possibility of using standard commercial balances for this purpose. Consequently, every investigator that selects the gravimetric method of measuring adsorption must himself construct, and often design, a balance that will meet his requirements.

Dozens of microbalances of different designs have been described in the literature (see, for example, the review articles [3-5]). These were designed for a great variety of purposes, including adsorption measurements. A critical examination of more than fifty papers describing balances of different designes showed that the most suitable balance for the investigation of adsorption on nonporous adsorbents is that of Gulbransen [6, 7], as improved by Rhodin [8]. Even this balance, however, has a somewhat low relative sensitivity, and it has some defects in design. It must be pointed out that almost all of the balances described were constructed without making the appropriate theoretical analysis and calculations.

The above considerations led us to set ourselves the following problem: to design and construct an adsorption balance having a relative sensitivity of about $1 \cdot 10^{-7}$ at a load of 1 g, the maximum change in the weight of the adsorbent due to adsorption being about 2 mg. The design was based on that of the torsion-beam microbalance.

Fig. 1. Diagram showing principle of the balance.

When the precise design had been decided, detailed calculations were made for the balance: a general equation was obtained for the sensitivity of a balance of this type, and all factors affecting the sensitivity were evaluated. The scheme of the balance is shown in Fig. 1. The short beam 1 (shoulder length 1 cm), made from fused quartz rods, is supported by two quartz threads 4 (each length 10 cm and diameter about 25 μ), which are almost horizontal and ensure that the beam will oscillate about its horizontal axis (they are analogous to the central prism in the analytical balance). At the ends of the beam the quartz threads 2 (diameter about 8 μ) are fused; they act as suspensions for cups containing adsorbent (8) and its counterpoise (3). When one of the supporting threads 4 is fused to the beam, a second thread 5 is fused on at the same time, and this serves as a torsion thread, its other end being fused to the axle of the graduated dial 6. The torsion thread is 15 cm in length and about 15 μ in diameter. An iron plate is rigidly attached to the graduated dial 6 so that the dial can be rotated with the magnet 7, which is placed outside the glass balance case.

We shall examine the working of the balance. Let us assume that the beam is first approximately balanced in the horizontal position by the selection of a counterpoise that is correct within 0.1 mg. With the aid of the magnet 7 the beam is then brought exactly into the "zero position", determined optically by means of a mirror attached to the beam; the optical arrangement will be described in detail below. The torsion angle of the torsion thread corresponding to the initial weight of the adsorbent is read on the dial 6, which is graduated in 1° intervals. Any subsequent change in the weight of the adsorbent – resulting from adsorption or desorption – causes the beam to be deflected from its zero position. This deflection is nullified by twisting the torsion thread, the torsion angle being proportional to the extent of adsorption or desorption. The torsion thread used permits twisting for 15 turns in each direction. The number of complete turns of the thread are read from a revolution counter attached to the magnet 7 (not shown in the figure).

The separation of the functions of the supporting and torsion threads enabled us to increase the robustness of the balance appreciably and to increase the permissible change in weight of the sample during the experiment. Otherwise, the total tension in the thread may attain 60-80 kg / sq.mm, which, although permissible for quartz threads of this diameter, is already close to the limiting value; accidental jolts during loading or weighing can easily break the balance.

Calculation showed that, in order to obtain the required sensitivity in a balance of this design, the zero position must be established accurate within $1 \cdot 10^{-8}$ radian. It is well known how difficult it is to obtain such a sensitivity by the measurement of small angles by the usual optical methods, for example, the mirror and scale method. In the present case the use of such methods is excluded since the nonuniform thickness of the evacuated glass balance case makes it impossible to observe the scale, and the incorporation of an optically plane glass window into the case would make the construction of the case extremely difficult. These difficulties were overcome by the use of an optical system that included photocells; the principle of the system is shown in Fig. 1.

A slightly divergent beam of light from a source and slit 11 falls on the balance mirror and is reflected through a lens (not shown on Fig. 1), which focuses an image of the slit, reduced in size, on the edge of a prism. The prism divides the beam of light into two parts, which fall on two photocells contained in the bridge circuit 9. When the beam is deflected, the light falling on the photocells is redistributed and the bridge is thrown out of balance, which is indicated by the reading of the galvanometer 10 in the diagonal of the bridge. It should be noted

that this arrangement, which enables small angles of the order of $1 \cdot 10^{-5}$ radian to be read directly with comparative ease, has a further very valuable property, namely: it enables small angles to be measured with the same accuracy even when the mirror is oscillating slightly. It is therefore unnecessary to provide special suspensions or foundations for apparatus that is liable to receive jolts from neighboring apparatus and machines, etc.

The balance was calibrated and its sensitivity was determined with the aid of observations on the variations in the buoyancies of two loads of known volume hung on the balance, the measurements being made in dry air. One load, a hollow glass sphere, had a volume of 4.5941 ± 0.0002 cc, the other, a platinum rod, had a volume of 0.0479 ± 0.0002 cc. The volumes of the loads were determined by the method of hydrostatic weighing on an analytical balance. Each load weighed about 1 g. When the pressure in the balance case was changed by 0.01 mm of mercury, the difference in the buoyancies of the two loads changed by about $8 \cdot 10^{-9}$ g; a range of pressures from 0 to 300 mm covered the whole of the working range of the balance. The calibration results showed that there was an excellent linear relationship between the torsion angle of the thread and the weight over the whole of the range investigated. The balance constructed on this principle had a sensitivity of $5.7 \cdot 10^{-8}$ g at a load of 1 g, and the permissible change of weight in the course of the experiment was 2.5 mg. It must be pointed out that the calculated sensitivity of the balance was in close accord with the value obtained experimentally in the calibration.

The calculations required for the design of the balance amounted essentially to the determination of the diameters and lengths of the threads (the supporting, torsion, and suspending threads), and they did not go outside the usual problems on elasticity in their scope. We will mention only that the diameter and length of the torsion thread are determined by the specified maximum change in weight and sensitivity. The absolute sensitivity of the balance can be calculated from the following formula, which we obtained from the conditions for balance of the beam:

$$\Delta P = \left[\frac{G\pi}{32}\left(\frac{d_1^4}{l_1} + \frac{2d_2^4}{l_2}\right) + \sqrt{PE\frac{\pi d_3^4}{64}} + (mb_2 + 2Pb_1)\right]\frac{\varphi}{a}, \qquad (1)$$

in which ΔP is absolute sensitivity; E and G are elasticity moduli of the first and second kinds for quartz; P is the load on the balance; d_1 and l_1 are the diameter and length of the torsion thread; d_2 and l_2 are the diameter and length of the supporting threads; d_3 is the diameter of the threads that suspend the loads; m is the weight of the beam itself; a is the length of the shoulder of the beam; b_1 is the distance between the axis of rotation of the beam and a line drawn between the points at which the tensions in the suspensions are applied to the beam; b_2 is the distance between the axis of rotation of the beam and the center of gravity of the beam itself; φ is the smallest measurable angle of rotation of the beam. In this equation the quantities b_1 and b_2 are very difficult to determine. In the calculation, therefore, it is necessary to assume a value of $(mb_2 + 2Pb_1)\frac{\varphi}{a}$ (which depends on the balancing of the beam) that is several times less than ΔP. The assembled balance must then be loaded with nominal weights, and the final balancing of the beam must be carried out in this condition until the calculated sensitivity is obtained. The value of $(mb_2 + 2Pb_1)\frac{\varphi}{a}$ will then be adjusted to the assumed value.

The general scheme of the apparatus is given in Fig. 2. The balance itself is assembled on a metal framework and is sealed in the balance case A, which is in the form of a sealed glass T-piece. The balance case is contained in an air thermostat T. The ampoule B containing the substance to be absorbed, which is first purified and degassed, is contained in the cryostat C, and before the adsorption measurements are started it is isolated from the balance by the glass membrane P. Before the experiment the whole system is subjected to prolonged evacuation, the balance then being heated to about 70° and the adsorbent to 180° – 400°, depending on its nature. When a vacuum of the order of 10^{-6} mm is attained, the apparatus is sealed off from the vacuum pumps and manometers by fusion of the constriction at D. The diaphragm P is then broken, and the adsorption measurements are begun.

The pressure in the balance case of the vapor to be adsorbed is varied with the aid of a cryostat. For

• The term $\sqrt{PE\frac{\pi d_3^4}{64}}$, which determines the value of the bending moment of the suspending thread (which is rigidly attached to the beam), was obtained by Popov's method [9].

substances for which the relationship between saturated vapor pressure and temperature is known, the pressure of the vapor can be calculated from the temperature of the cryostat. It can also be measured directly, and for this purpose a second ampoule E is placed in the cryostat; this contains the substance under investigation, and it is attached to a McLeod gage M_1 and a U-shaped mercury manometer M_2.

Fig 2 General scheme of adsorption apparatus

Fig. 3. Construction of cryostat and controlling thermometer.

Such an arrangement was dictated by the necessity for the exclusion of the vapors of mercury and vacuum grease from the space containg the adsorbent, for it was found that the trap containing gold turnings generally used for the absorption of mercury vapor does not give satisfactory protection, and that the adsorption of vapors from vacuum grease is quite appreciable at the given balance sensitivity. Moreover, the presence of vacuum grease limits the choice of substances for adsorption in this apparatus.

We have designed and constructed a special cryostat for use with this apparatus; its construction is shown in Fig. 3. A massive copper block is cooled by a copper rod B, the lower end of which is immersed in liquid nitrogen. We examined the possibility of controlling the temperature of the cryostat roughly and cooling the cryostat rapidly by varying the amount of heat conducted from the block to the liquid nitrogen. With this in view, the upper end D of the rod B was made of synthetic resin of poor thermal conductivity. When the rod is displaced in the vertical direction, there is a change in the area of thermal contact between the copper of the rod B and the conical copper tube E, which is in good thermal contact with the block; the rate at which the block cools changes correspondingly.

The high thermal conductivity of copper enables a fairly uniform temperature to be maintained throughout the block. However, to reduce possible temperature gradients, the block is cooled in its central region and the electric heater is on its outer surface. With the same object in view, the ampoules containing the substance under investigation and the controlling and measuring thermometers are in holes arranged symmetrically in the block with respect to heater and cooler. A 5-cm layer of the porous synthetic resin PS-4 was used as thermal insulation for the block.

The precise control of the temperature of the cryostat is effected automatically, and the temperature can be maintained constant at any value in the range from −150° to + 50°. The automatic thermostating is effected with the aid of a controlling platinum resistance thermometer (Fig. 3c), an electron-tube circuit, and a heater. The platinum thermometer is designed so as to ensure extremely good thermal contact between it and the cryostat block, which appreciably reduces the thermal inertia of the thermometer. The thermometer was made from a platinum wire 50 μ in diameter, which was laid in a thread cut on the copper tube A. The wire was insulated from the copper tube with a layer of polymerized Bakelite. The tube has belts C that are ground to fit the hole in the cryostat block. The thermometer leads are fixed in the tube B, which is made of synthetic resin. The resistance of the thermometer is about 73 ohms at room temperature.

Fig. 4. Adsorption isotherm for methanol vapor on barium sulfate at 25°.

Fig. 5. Adsorption isotherm for heptane vapor on homogeneous finely porous silica gel at 20°

The controlling thermometer forms part of a Wheatstone bridge supplied with 400-cycles 2-v a.c. current from a low-power single-tube generator. The bridge is connected through a transformer to a first-stage amplifier, which is a triple-cascade aperiodic arrangement of 6Zh8 electron tubes with a limited range of emitted frequencies (100 to 800 cycles). The first-stage amplifier is connected through a copper oxide rectifier to a final-stage constant-current amplifier; the anode current of the last electron tube feeds the cryostat heater. The cryostat heater is made of 0.1-mm nichrome wire laid in a thread cut on the outer surface of the block. The wire is insulated from the block by means of Bakelite, as in the case of the controlling thermometer. The resistance of the heater is 2100 ohms.

This arrangement is not inferior in sensitivity to the usual arrangements employed for this purpose, i.e. arrangements incorporating a mirror, a galvanometer, a photocell, and a thyratron relay, and it is superior to them in reliability and convenience. A change in the resistance of the controlling thermometer by 0.01 ohm, i.e. 0.013%, brings about a change in the current in the cryostat heater of 2 ma when the average working current is 10-20 ma. The temperature of the cryostat can be maintained within ± 0.005° for several hours. By way of example, in our work with methanol at pressures in the region of 1 mm, the pressure in the balance case was maintained constant within ± 0.04%.

In order to verify the method, some special experiments were carried out: 1) The working of the cryostat was checked, for which purpose we investigated the dependence of the saturated vapor pressure of heptane on temperature. The experimental results were in close accord with data from the literature. 2) Two series of measurements on well-studied systems were carried out.

1. The adsorption isotherm for methanol vapor was determined at 25° on barium sulfate having a specific surface of 7 sq.m/g (Fig. 4). All of the curves represent the same isotherm, but the scale is subjected to successive

multiplications by 10 with respect to the relative pressure axis. The circles represent our experimental values, and continuous curves are drawn through them. The black spots represent the experimental values obtained by Bering and Serpinsky [1] by the method of independent weighing.

2. The adsorption isotherm for heptane vapor was determined at 20° on homogeneous finely porous silica gel having a specific surface of about 420 sq.m/g (Fig. 5). The signs used are the same as in the preceding graph. The black spots represent the experimental values of Kiselev and coworkers [10], who used an apparatus based on the usual spring sorption balance. It will be seen from these two graphs that the isotherms that we obtained agree quite satisfactorily with those obtained for the same substances by other workers using other methods. It should be noted that in the investigation of adsorption on silica gel, the amount taken was only 12 mg, since with larger amounts the extent of adsorption would have been outside the working range of the balance.

Thus, these verifying experiments showed that the method is suitable for the investigation of the adsorption of vapors on nonporous crystalline adsorbents. Our first systematic measurements of adsorption with this apparatus will form the subject of our second communication.

SUMMARY

1. A precision adsorption apparatus was constructed for the investigation of the adsorption of vapors on nonporous solid adsorbents. It consists of a balance having a sensitivity of $5.7 \cdot 10^{-8}$ g at a load of 1 g and a cryostat for temperatures from −150° to + 50° in which the temperature can be maintained constant within ± 0.005. In this apparatus the effect of mercury vapors and vacuum grease on the adsorbent is excluded, and this increases the reliability of the results and, at the same time, increases the choice of vapors for investigation.

2. Experiments designed to verify the method were carried out, and these showed that it is suitable for accurate adsorption measurements on model adsorbents having specific surfaces of the order of 1 sq.m/g.

EFFECT OF THE TEMPERATURE FACTOR ON THE RATE OF CORROSION OF METALS IN ELECTROLYTES

V. V. Gerasimov, G. V. Akimov *, and I. L. Rozenfeld.

In the theory of corrosion of metals, the hypothesis of the limiting (controlling) factor has received wide application [1, 2]. However, the effect of the limiting factor on the rate of corrosion at high temperatures has not been adequately studied. With the object of determining the effect of temperature on the rate of the corrosion process, we studied the dependence of the current of an iron-zinc couple with varying external resistance on the temperatures of the electrolytes in the cathode and anode spaces. This enabled us to study the part played by the temperature factor for various kinds of control.

EXPERIMENTAL

The results of the experiments showed that the corrosion current increases appreciably with temperature only when the rise in temperature occurs in the space surrounding the electrode associated with the reaction that determines the overall rate. This is illustrated by Fig. 1, from which it follows that, for an iron-zinc couple ($F_a : F_k = 500 : 1$) working with cathodic-ohmic limitation, elevation of the temperature of the electrolyte in the anode space does not result in increased current (see Curve 1).

Fig. 1. Dependence of the current of an iron-zinc couple ($F_a : F_k = 1 : 500$) on resistance in 1.0 N NaCl + 0,1N HCl; o- cathode temperature 20°, anode temperature 20°; Δ cathode temperature 20°, anode temperature 80° · x - cathode temperature 80°, anode temperature 20°.

Fig. 2. Dependence of the relative increase of the corrosion current of an iron-zinc couple with rise in temperature on the percentage cathodic limitation.

By changing the external resistance we succeeded in varying the degree of cathodic control from 0 to 60% and were thus able to study the relative change in the corrosion current with increase in degree of cathodic control (Fig. 2). It follows from Fig. 2 that there is a linear relationship between the relative increase in corrosion current and the percentage cathodic limitation. Hence, the more the system is cathodically polarized, the greater will be the effect of change of temperature on the increase in corrosion current. This conclusion is confirmed by a study of the working of a copper-magnesium couple in various electrolytes (Fig. 3). The greatest increase of corrosion with temperature is observed in a 1.5% solution of sodium chloride, i.e. in an electrolyte for which the extent of cathodic control is great for the given couple.

* Deceased

Analysis of the working of the corrosion couples iron - zinc ($F_k : F_a = 1 : 100$) and magnesium - copper ($F_a : F_k = 1 : 100$) having electrodes arranged in one plane, and also of a real microcouple (alloy of zinc with 0.92% of iron), confirmed the laws considered above (Table 1). - The corrosion process of an iron-zinc couple proceeds with cathodic control, and in this system the rate of corrosion increases mainly as a result of increase in the rate of the cathode process. In the corrosion of the magnesium-copper couple anodic and cathodic control are comparable in extent, and with rise in temperature corrosion increases as a result of rise in the rates of both cathodic and anodic processes. The rate of the corrosion process in a real microcouple is determined by the kinetics of the cathode reaction, and with rise of temperature, therefore, corrosion increases as a result of the facilitation of this reaction.

Fig. 3. Dependence of the relative increase in the corrosion current of a magnesium-copper temperature: 1) in 1.5% NaCl; 2) in distilled water.

In the corrosion of metals as the result of the working of a microcouple [2,3,4] the relative amount of ohmic control is negligible and the increase in the conductance of the solution with rise in temperature has no effect on the rate of corrosion; analysis of the working of the microcouple $Zn/FeZn_7$ leads to the same conclusion. In the general case, the variation of the rate of corrosion with rise of temperature is influenced mostly by the variation with temperature of the factor controlling the corrosion process. In macrosystems it is essential to keep to the following rule: so that corrosion in systems in which macrocouples are formed should increase with rise in temperature as little as possible, it is essential that the controlling factor in the macrocouple should be the factor whose resistance would fall with temperature to the least extent.

TABLE 1

Analysis of the Working of Corrosion Couples in 1.0 N NaCl + 0.1 N HCl at Various Temperatures

System investigated	Corrosion current I (ma)		$I_{80°} : I_{20°}$	Extent of limitation (%)			Factor increasing corrosion		
	20°	80°		Anodic	Cathodic	Ohmic	Facilitation of anode process (%)	Facilitation of cathode process (%)	Increase in conductance of solution (%)
Model couple Fe—Zn ($F_a : F_k = 100 : 1$)	0.52	1.7	3.3	3.2	91.3	5.5	7.3	9.2	0.7
Model couple Mg—Cu ($F_k : F_a = 100 : 1$)	12.0	29.0	2.4	47.7	46.0	6.3	55.5	34.0	10.5
Microcouple $Zn/FeZn_7$	3.0	12.0	4	10.7	88.3	1.0	2.55	97.45	0

In actual cases of corrosion the rate of the cathode process may be limited by the rate of ionization of oxygen or the rate of discharge of hydrogen ions. In unstirred electrolytes processes of oxygen depolrization may be controlled also by the rate of the diffusion of oxygen. It was therefore considered to be of interest to study how the rate of corrosion changes with temperature for various forms of cathode process. With this in view we studied the working of the corrosion couples copper-iron, copper-zinc, and copper-magnesium in 1.0 N NaCl + 0.123 N H_2O_2. The electrode areas were 0.2 sq. cm, and the temperature was varied from 0° to 20°. From the corrosion diagrams (Fig. 4) it follows, in the first place, that in all of the couples studied the limiting factor is the rate of the cathode process and, in the second place, that the current of the copper-magnesium couple is determined by the rate of discharge of hydrogen ions, the current of the copper-zinc couple by the rate of diffusion of hydrogen peroxide, and the current of the copper-iron couple by the rate of ionization of oxygen. The temperature coefficients for the rates of corrosion of the couples investigated are given in Table 2.

Analysis of the working of the corrosion couples iron + zinc ($F_k : F_a = 1 : 100$) and magnesium - copper ($F_a : F_k = 1 : 100$) having electrodes arranged in one plane, and also of a real microcouple (alloy of zinc with 0.92% of iron), confirmed the laws considered above (Table 1). The corrosion process of an iron-zinc couple proceeds with cathodic control, and in this system the rate of corrosion increases mainly as a result of increase in the rate of the cathode process. In the corrosion of the magnesium-copper couple anodic and cathodic control are comparable in extent, and with rise in temperature corrosion increases as a result of rise in the rates of both cathodic and anodic processes. The rate of the corrosion process in a real microcouple is determined by the kinetics of the cathode reaction, and with rise of temperature, therefore, corrosion increases as a result of the facilitation of this reaction.

Fig. 3. Dependence of the relative increase in the corrosion current of a magnesium-copper temperature: 1) in 1.5% NaCl; 2) in distilled water.

In the corrosion of metals as the result of the working of a microcouple [2,3,4] the relative amount of ohmic control is negligible and the increase in the conductance of the solution with rise in temperature has no effect on the rate of corrosion. analysis of the working of the microcouple Zn/ $FeZn_7$ leads to the same conclusion. In the general case, the variation of the rate of corrosion with rise of temperature is influenced mostly by the variation with temperature of the factor controlling the corrosion process. In macrosystems it is essential to keep to the following rule: so that corrosion in systems in which macrocouples are formed should increase with rise in temperature as little as possible, it is essential that the controlling factor in the macrocouple should be the factor whose resistance would fall with temperature to the least extent.

TABLE 1

Analysis of the Working of Corrosion Couples in 1.0 N NaCl + 0.1 N HCl at Various Temperatures

System investigated	Corrosion current I (ma)		$I_{80°} : I_{20°}$	Extent of limitation (%)			Factor increasing corrosion		
	20°	80°		Anodic	Cathodic	Ohmic	Facilitation of anode process (%)	Facilitation of cathode process (%)	Increase in conductance of solution (%)
Model couple Fe–Zn ($F_a : F_k = 100 : 1$)	0.52	1.7	3.3	3.2	91.3	5.5	7.3	9.2	0.7
Model couple Mg–Cu ($F_k : F_a = 100 : 1$)	12.0	29.0	2.4	47.7	46.0	6.3	55.5	34.0	10.5
Microcouple Zn/ $FeZn_7$	3.0	12.0	4	10.7	88.3	1.0	2.55	97.45	0

In actual cases of corrosion the rate of the cathode process may be limited by the rate of ionization of oxygen or the rate of discharge of hydrogen ions. In unstirred electrolytes processes of oxygen depolrization may be controlled also by the rate of the diffusion of oxygen. It was therefore considered to be of interest to study how the rate of corrosion changes with temperature for various forms of cathode process. With this in view we studied the working of the corrosion couples copper-iron, copper-zinc, and copper-magnesium in 1.0 N NaCl + 0.125 N H_2O_2. The electrode areas were 0.2 sq. cm, and the temperature was varied from 0° to 20°. From the corrosion diagrams (Fig. 4) it follows, in the first place, that in all of the couples studied the limiting factor is the rate of the cathode process and, in the second place, that the current of the copper-magnesium couple is determined by the rate of discharge of hydrogen ions, the current of the copper-zinc couple by the rate of diffusion of hydrogen peroxide, and the current of the copper-iron couple by the rate of ionization of oxygen. The temperature coefficients for the rates of corrosion of the couples investigated are given in Table 2.

TABLE 2

Temperature Coefficients for the Corrosion Rates of the Couples Copper-Iron, Copper-Zinc, and Copper-Magnesium in 1.0 N NaCl + 0.123 N H_2O_2

Corrosion couple	Limiting Factor	Temperature coefficient $\gamma_k = \frac{K_{30} - K_{10}}{20 \cdot K_{10}} \cdot 100$
Copper-iron	Rate of ionization oxygen	10.6
Copper-zinc	Rate of transport of hydrogen peroxide	3.5
Copper-magnesium	Rate of discharge of hydrogen ions	7.8

Fig. 4. Polarization curves in 1.0 N NaCl + 0.123 N H_2O_2. 1) cathodic polarization of copper; 2) anodic polarization of iron; 3) anodic polarization of zinc; 4) anodic polarization of magnesium.

It follows from the data in Table 2 that the rate of a corrosion process limited by the rate of transport of the oxidizing agent does not rise with rise in temperature so rapidly as the rates of corrosion processes limited by the rate of the reduction of the oxidizing agent and the rate of discharge of hydrogen ions. The higest temperature coefficient is found when the cathode process is determined by the rate of ionization of oxygen.

SUMMARY

1. The effect of temperature on the rate of corrosion processes having different kinds of limitation was studied for model corrosion couples and for a real microcouple—an alloy of zinc with 0.92% of iron.

2. It was shown that the variation of the rate of the corrosion process with change of temperature is determined primarily by the variation of the factor controlling the corrosion process.

3. The effect of temperature on the rate of corrosion was studied for different kinds of cathodic control: the rate of discharge of hydrogen ions, the rate of diffusion of oxidizing agent (hydrogen peroxide), and the rate of ionization of oxygen. It was shown that the rate of a corrosion process that is limited by the rate of ionization of oxygen shows the greatest increase with rise in temperature, and the rate of the process limited by the rate of transport of the oxidizing agent shows the least increase.

DERIVATIVES OF UNSATURATED PHOSPHONIC ACIDS

COMMUNICATION 13. DIESTER OF 2-INDENYLPHOSPHONIC ACID

K. N. Anisimov and A. N. Nesmeyanov

Diesters of 2-indenylphosphonic acid were prepared by the method used for the synthesis of 2-aryl and 2-alkoxy-vinylphosphonic esters, namely, by the action of 2-indenylphosphonic dichloride on alcohols in presence of pyridine in a benzene or petroleum ether medium [1-3]:

2-Indenylphosphonic esters are clear liquids of high boiling point. They are all soluble in organic solvents. Below, we give a table of constants for the esters obtained.

TABLE

Formula of compound	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
	146 (2)	1.5603	1.2109
	150 (1)	1.5398	1.1410
	162 (1)	1.5298	1.1392
	169 (1)	1.5514	.1354
	206 (2)	1.5100	1.0220

EXPERIMENTAL

Dimethyl 2-Indenylphosphonate 
A solution of 11.65 g of 2-indenylphosphonic dichloride in 20 ml of benzene was added to a stirred mixture of 150 g of dry benzene, 7.9 g of pyridine, and 3.2 g (4 ml was taken) of absolute methanol. When reaction was complete, pyridine hydrochloride was separated and the filtrate was washed with 3% sodium carbonate solution and dried over sodium sulfate. Excess of alcohol and benzene was distilled off, and vacuum fractionation of the residue yielded 8.5 g (50.3%) of a substance having b.p. 146° (2 mm); n_D^{20} 1.5603, d_4^{20} 1.2109.

Found %: P 13.70; 13.78

$C_{11}H_{17}O_3P$. Calculated %: P 13.83

All of the other esters of 2-indenylphosphonic acid were prepared by this method.

Diethyl 2-Indenylphosphonate 
2-Indenylphosphonic dichloride (12 g) was added to 8.2 g of pyridine and 5 g of absolute ethanol. Vacuum fractionation gave 7.8 g (60%) of a substance having b.p. 150° (1mm); n_D^{20} 1.5298; d_4^{20} 1.1410.

Found %: P 11.89; 11.99

$C_{13}H_{17}O_3P$ Calculated %: P 12.31

Dipropyl 2-Indenylphosphonate 
2-Indenylphosphonic dichloride (10g) was gradually added to 15.1 g of absolute propyl alcohol and 6.8 g of pyridine. The product, amounting to 7 g (60%), had b. p. 162° (1mm); n_D^{20} 1.5298; d_4^{20} 1.1392.

Found %: P 10.49; 10.40

$C_{15}H_{21}O_3P$. Calculated %: P 10.71

Diallyl 2-Indenylphosphonate 
Pyridine (7.9 g) and absolute allyl alcohol (5.8 g) were added to 11.65 g of 2-indenylphosphonic dichloride. The reaction was carried out in a benzene medium. The product, amounting to 8.2 g (61 %), had b.p.169° (1mm); n_D^{20} 1.5514; d_4^{20} 1.1354.

Found %: P 11.05; 11.17

$C_{15}H_{17}O_3P$. Calculated %: P 11.23

Dihexyl 2-Indenylphosphonate 
2-Indenylphosphonic dichloride (13 g) was added to a stirred solution of 8.8 g of pyridine and 11.3 g of hexyl alcohol in 170 ml of dry benzene. The product, amounting to 12.8 g (63%), had b.p. 206° (2mm); n_D^{20} 1.5100; d_4^{20} 1.0220

Found %: P 8.55; 8.47

$C_{21}H_{33}O_3P$. Calculated %: P 8.51

SUMMARY

Five esters of 2-indenylphosphonic acid were prepared and characterized.

DERIVATIVES OF UNSATURATED PHOSPHONIC ACIDS

COMMUNICATION 17. DERIVATIVES OF STYRYLPHOSPHONIC ACID

K. N. Anisimov and A. N. Nesmeyanov

N,N,N,N-Tetraalkyl-P-styrylphosphonic Diamides. N,N,N,N-Tetraalkyl derivatives of P-styrylphosphonic diamide were prepared in the same way as the tetraalkyl derivatives of P-2-alkoxyvinylphosphonic diamide, i.e. by reaction of one molecular equivalent of styrylphosphonic dichloride with four molecular equivalents of a dialkylamine in a petroleum ether or benzene medium [1]:

$$C_6H_5-CH=CHPOCl_2 + 4R_2NH = C_6H_5-CH=CHPO[N(R_2)]_2 + 2R_2NH\cdot HCl.$$

In this way we synthesized tetramethyl, tetraethyl, tetrapropyl, tetrabutyl, and bispentamethylene derivatives of P-styrylphosphonic diamide. The tetramethyl and tetrapropyl derivatives are viscous liquids having high boiling points and refractive indices; the other compounds are crystalline substances, soluble in the usual organic solvents, but not in water.

The N,N,N,N,- tetraalkyl - P - styrylphosphonic diamides obtained are listed in Table 1.

TABLE 1

Formula of compound	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
$C_6H_5-CH=CHPO[N(CH_3)_2]_2$	180 (2)	1.5665	1.0818
$C_6H_5-CH=CHPO[N(C_2H_5)_2]_2$	103.5*		
$C_6H_5-CH=CHPO[N(C_3H_7\text{-}n)_2]_2$	192 (2)	1.5290	1.0060
$C_6H_5-CH=CHPO[N(C_4H_9\text{-}n)_2]_2$	39 - 40*		
$C_6H_5-CH=CHPO[NC_5H_{10}]_2$	135 - 136*		

* Melting point

O,O-Dialkyl Styrylphosphonothioates. We prepared O,O-dimethyl and O,O-diethyl styrylphosphonothioates by reaction of styrylphosphonothioic dichloride with sodium alkoxides in methanol and ethanol, respectively:

$$C_6H_5-CH=CHPSCl_2 + 2NaOR = C_6H_5CH=CHPS(OR)_2 + 2NaCl.$$

The O,O-dialkyl styrylphosphonothioates obtained are clear liquids, insoluble in water, but soluble in many organic solvents. The constants of these compounds are given in Table 2.

TABLE 2

Formula of compound	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
$C_6H_5-CH=CHPS(OCH_3)_2$	124 (1)	1.5890	1.1794
$C_6H_5-CH=CHPS(OC_2H_5)_2$	130 (1)	1.5658	1.1067

S,S-Dialkyl and Diaryl Styrylphosphonodithioates. We obtained two compounds of this series — S,S-diethyl and S, S-diphenyl styrylphosphonodithioates. The first of these was synthesized by the action of styrylphosphonic dichloride on sodium ethyl mercaptide in an ether medium. The diethyl ester is a viscous liquid of unpleasant odor,

soluble in the usual organic solvents. The second ester was prepared by the action of styrylphosphonic dichloride on benzenethiol in presence of pyridine in a benzene medium. It is a crystalline substance, insoluble in water, but soluble in organic solvents. Data relating to these compounds are given in Table 3.

TABLE 3

Formula of compound	B.p. in °C(p in mm)	n_D^{20}	d_4^{20}
$C_6H_5-CH=CHPO(SC_6H_5)_2$	168(1)	1.6248	1.1469

EXPERIMENTAL

N,N,N,N-Tetramethyl-P-styrylphosphonic Diamide $C_6H_5CH=CHPO[N(CH_3)_2]_2$. Styrylphosphonic dichloride (11.05 g) was added dropwise to a stirred solution of 9 g of dimethylamine in a cooled mixture of 70 ml of petroleum ether and 30 ml of benzene. When the whole of the acid chloride had been added, stirring was continued for two hours. On the next day the reaction mixture was heated in a water bath for two hours at 30-35°. The precipitate was filtered off and washed twice with petroleum ether. The filtrate was treated with small portions of saturated caustic soda solution to remove traces of dimethylamine hydrochloride, dried over calcined potassium carbonate, and fractionated. The product isolated, amounting to 6 g(50.8%), had b.p. 180° (2 mm); n_D^{15} 1.5665, d_4^{20} 1.0818.

Found %: N 11.39; 11.56

$C_{10}H_{15}OPN_2$. Calculated %: N 11.78

N,N,N,N-Tetraethyl-P-styrylphosphonic Diamide $C_6H_5CH=CHPO[N(C_2H_5)_2]_2$ Styrylphosphonic dichloride (11.05 g) was added gradually to a solution of 14.5 g of diethylamine in 150 ml of a mixture of petroleum ether and benzene. The product, amounting to 8 g(78.4%), melted at 103.5°.

Found %: N 9.10; 9.10

$C_{18}H_{27}OPN_2$. Calculated %: N 9.52

N,N,N,N-Tetrapropyl-P-styrylphosphonic Diamide $C_6H_5CH=CHPO[N(C_3H_7-n)_2]_2$. Reaction of 20.2 g of dipropylamine and 11.05 g of styrylphosphonic dichloride gave 13 g of tetrapropyl-P-styrylphosphonic diamide, b.p. 192° (2 mm); n_D^{20} 1.5290; d_4^{20} 1.0050.

Found %: P 8.76; 8.97

$C_{22}H_{39}PON_2$ Calculated %: P 8.83

N,N,N,N-Tetrabutyl-P-styrylphosphonic Diamide $C_6H_5CH=CHPO[N(C_4H_9-n)_2]_2$. Styrylphosphonic diamide (11 g) was added to a solution of 27 g of dibutylamine in 150 ml of petroleum ether. The usual treatment yielded 8 g of tetrabutyl-P-styrylphosphonic diamide, m.p. 39-40°.

Found %: P 7.59; 7.77

$C_{26}H_{47}PON_2$. Calculated %: P 7.63

N,N-Dispentamethylene-P-styrylphosphonic Diamide (Styrylphosphonic Dipiperidide) $C_6H_5CH=CHPO\cdot[N-C_5H_{10}]_2$. Styrylphosphonic dichloride (11 g) was added to a cooled(ice water) stirred solution of 16 g of piperidine in 125 ml of petroleum ether. The product was a crystalline substance which melted at 135-136° after being recrystallized from ether.

Found %: N 8.74; 8.65

$C_{18}H_{27}PON_2$ Calculated %: N 8.80

O,O-Dimethyl Styrylphosphonothioate $C_6H_5CH=CHPS(OCH_3)_2$. Styrylphosphonothioic dichloride (11.85 g) was added with cooling and stirring to sodium methoxide prepared from 2.3 g of sodium and 60 ml of absolute methanol. When reaction was complete the mixture was diluted with 120 ml of absolute ether. The product isolated, amounting to 8.3 g (65.3%), had b. p. 124° (1 mm); n_D^{20} 1.5890; d_4^{20} 1.1704.

Found %: P 13.47; 13.36

$C_{10}H_{13}O_2PS$. Calculated %: P 13.59

O,O-Diethyl Styrylphosphonothioate $C_6H_5CH=CPS(OC_2H_5)_2$. Styrylphosphonothioic dichloride (11.85 g) was added to a stirred solution of sodium ethoxide, prepared from 2.3 g of sodium and 70 ml of absolute ethanol. The product isolated, amounting to 7.6 g (55.4%), had b. p. 130° (1 mm); n_D^{20} 1.5658; d_4^{20} 1.1067.

Found %: P 12.00; 12.17

$C_{12}H_{17}O_2PS$. Calculated %: P 12.10

S,S-Diethyl Styrylphosphonodithioate $C_6H_5CH=CHPO(SC_2H_5)_2$. Styrylphosphonic dichloride (11.05 g) was added to a cooled stirred solution of sodium ethyl mercaptide, prepared in absolute ether from 2.3 g of sodium and 9 g of ethanethiol. The product isolated, amounting to 8 g (58.8%), had b. p. 168° (1 mm); n_D^{20} 1.6248; d_4^{20} 1.1469.

Found %: P 11.31; 11.39

$C_{12}H_{17}OPS_2$. Calculated %: P 11.39

S,S-Diphenyl Styrylphosphonodithioate $C_6H_5CH=CHPO(SC_6H_5)_2$. Styrylphosphonic dichloride (11.05 g) was added to a cooled stirred solution of 11 g of benzenethiol and 7.9 g of pyridine in 150 ml of dry benzene. The product isolated (9.8 g) was S,S-diphenyl styrylphosphonodithioate, m.p. 117°.

Found %: C 65.68; 65.67; H 4.93; 4.74; S 17.23; 17.59

$C_{20}H_{17}OPS_2$. Calculated %: C 65.48; H 4.61; S 17.39

SUMMARY

Five N-substituted P-styrylphosphonic diamides, two O,O-diesters of styrylphosphonothioic acid, and two S,S-diesters of styrylphosphonodithioic acid were synthesized and characterized.

DERIVATIVES OF UNSATURATED PHOSPHONIC ACIDS

COMMUNICATION 18. 2-(ALKYLTHIO)VINYLPHOSPHONIC DICHLORIDES AND THEIR DERIVATIVES

K. N. Anisimov, N. E. Kolobova, and A. N. Nesmeyanov

Derivatives of unsaturated phosphonic acids, a class of compounds that has received very little study, are of great interest. Continuing our study of the addition of PCl_5 to vinyl ethers, we decided to investigate examples in which vinyl thioethers were used. These thioethers have become accessible as a result of a simple and convenient method of synthesis developed by Shostakovsky and his students [1].

We consider that PCl_5 adds to vinyl thioethers in the same way as it adds to vinyl ethers, i.e. in accord with Markovnikov's rule:

$$RS-CH=CH_2 + 2PCl_5 = RSCHCl-CH_2PCl_4 \cdot PCl_5$$
$$RSCHCl-CH_2PCl_4 \cdot PCl_5 + 2SO_2 = RSCH=CHPOCl_2 + 2SOCl_2 + POCl_3 + HCl.$$

By this reaction we prepared 2-(ethylthio)- and 2-(butylthio)-vinylphosphonic dichlorides in 68-80% yield. Constants of these compounds are given in Table 1.

TABLE 1

Formula of compound	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
$C_2H_5-S-CH=CHPOCl_2$	117(2)	1.5720	1.3938
$n-C_4H_9-S-CH=CHPOCl_2$	120-122(1)	1.5505	1.2845

2-(Alkylthio)vinylphosphonic dichlorides are liquids of unpleasant odor which rapidly decolorize bromine water and which react with alcohols and dialkylamines. They are soluble in many organic solvents.

2-(Alkylthio)vinylphosphonic Esters. In order to make a more detailed study of the properties of 2-(alkylthio)vinylphosphonic dichlorides, we undertook the synthesis of diesters by the method of Milobendzki and Sachnowski [2].

$$RS-CH=CHPOCl_2 + 2ROH + 2C_5H_5N = RS-CH=CHPO(OR)_2 + 2C_5H_5N \cdot HCl.$$

By this method we obtained the dipropyl, dibutyl, diallyl, and dihexyl esters of 2-(ethylthio) and 2-(butylthio)-vinylphosphonic acids in 75-83% yield. Constants of these compounds are given in Table 2.

Diesters of 2-alkylthio)vinylphosphonic acids are clear liquids, which are readily distilled under reduced pressure, rapidly decolorize bromine water, and are of good solubility in organic solvents, but insoluble in water.

N,N,N,N-Tetraalkyl-P-2-(alkylthio)vinylphosphonic Diamides. We prepared tetraalkyl-P-2(alkylthio) vinylphosphonic diamides by the method of Michaelis [3].

$$RS-CH=CHPOCl_2 + 4R_2NH = RS-CH=CHPO[N(R)_2]_2 + 2R_2NH \cdot HCl.$$

By this reaction we obtained 2-(ethylthio)vinylphosphonic dipiperidide in 80-82% yield ($C_2H_5-S-CH=CHPO[NC_5H_{10}]_2$, m. p. 62.5°.

EXPERIMENTAL

2-(Ethylthio)vinylphosphonic Dichloride $C_2H_5SCH=CHPOCl_2$. To a stirred cooled (ice water) benzene suspension of 83 g of PCl_5, 17.6 g of ethyl vinyl sulfide (b.p. 91.9-92.5°, n_D^{20} 1.4756) was added dropwise. When addition of ethyl vinyl sulfide was complete, the reaction mixture became very hot, and there was a copious evolution of hydrogen chloride. The resulting crystalline complex was left overnight. On the next day the reaction mixture was subjected to the action of sulfur dioxide, which was passed until the crystalline mass dissolved completely. After removal of solvent phosphoryl chloride, and thionyl chloride by distillation, the residue was vacuum-fractionated and yielded 28 g (68 %) of a substance having b.p. 117° (2 mm); n_D^{20} 1.5720; d_4^{20} 1.3936

Found %: P 14.87; 14.91
$C_4H_7PSOCl_2$. Calculated %: P 15.12

2-(Butylthio)vinylphosphonic Dichloride $n-C_4H_9SCH=CHPOCl_2$. 2-(Butylthio)vinylphosphonic dichloride was prepared under the conditions described above, 27 g of butyl vinyl sulfide being added gradually to 85 g of PCl_5. The product, amounting to 37 g (82 %), had b.p. 120-122° (1 mm); n_D^{20} 1.5505; d_4^{20} 1.2845

Found %: P 13.46; 13.53
$C_6H_{11}PSOCl_2$. Calculated %: P 13.30

Dipropyl 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OC_3H_7-n)_2$. 2-(Ethylthio)vinylphosphonic dichloride (10.3 g) was added to a stirred mixture of 100 ml of benzene, 6.2 g of propyl alcohol, and 8.5 g of pyridine. The product, amounting to 8 g, had b.p. 147° (2 mm); n_D^{20} 1.4930; d_4^{20} 1.0807

Found %: C 47.28; 47.20; H 8.39; 8.33
$C_{10}H_{21}PSO_3$. Calculated %: C 47.61; H 8.33

Dibutyl 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OC_4H_9-n)_2$. 2-(Ethylthio)vinylphosphonic dichloride (10 g) was added to a stirred mixture of 7.6 g of butyl alcohol, 8.3 g of pyridine, and 150 ml of dry benzene. The product (9.5 g), obtained by vacuum fractionation, had b.p. 168° (3mm); n_D^{20} 1.4890; d_4^{20} 1.0317

Found %: C 50.98; 51.11; H 9.01; 8.96
$C_{12}H_{25}PSO_3$. Calculated %: C 51.42; H 8.92

Diallyl 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OC_3H_5)_2$. 2-(Ethylthio)vinylphosphonic dichloride (10.2 g) was caused to react with 5.8 g of allyl alcohol in presence of 8g of pyridine. Vacuum fractionation yielded 8.3 g of a substance having b.p. 134° (1 mm); n_D^{20} 1.5120; d_4^{20} 1.1119

Found %: P 11.98; 12.11
$C_{10}H_{17}PSO_3$. Calculated %: P 12.50

Dihexyl 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OC_6H_{13}-n)_2$. This substance (14.5 g) was obtained by reaction of 10.2 g of 2 (ethylthio)vinylphosphonic dichloride with 10.5 g of hexyl alcohol in presence of 8.2 g of pyridine. It had b.p. 165° (1 mm); n_D^{20} 1.4808; d_4^{20} 1.0059

Found %: P 9.39; 9.22
$C_{18}H_{39}PSO_3$. Calculated %: P 9.50

Bis(2-methoxyethyl) 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OCH_2CH_2OCH_3)_2$. When treated with 7.6 g of 2-methoxyethanol and 8 g of pyridine, 10.5 g of 2-(ethylthio)vinylphosphonic dichloride gave 9.2 g of a substance having b.p. 160-161° (1 mm); n_D^{20} 1.4925; d_4^{20} 1.1512

Found %: P 10.66; 10.79
$C_{10}H_{21}PO_5S$. Calculated %: P 10.91

Bis(2-ethoxyethyl) 2-(Ethylthio)vinylphosphonate $C_2H_5SCH=CHPO(OCH_2CH_2OC_2H_5)_2$. Reaction between 10.2 g of 2-(ethylthio)vinylphosphonic dichloride, 9 g of 2-ethoxyethanol, and 8 g of pyridine gave 12.5 g of a substance having b.p.168° (1 mm); n_D^{20} 1.4865; d_4^{20} 1.1056

Found %: P 9.91; 9.87
$C_{12}H_{25}PO_5S$. Calculated %: P 9.33

2-(Ethylthio)vinylphosphonic Dipiperidide $C_2H_5SCH=CHPO$ 
Reaction of 15 g of 2-(ethylthio)vinylphosphonic dichloride with 25 g of piperdine in a mixture of petroleum ether and diethyl ether gave 16 g of the dipiperidide, m. p. 62.5°.

Found %: P 10.72; 10.66

$C_{14}H_{27}PON_2S$. Calculated %: P 10.26

Dibutyl 2-(Butylthio)vinylphosphonate n-$C_4H_9SCH=CHPO(OC_4H_9\text{-}n)_2$. Reaction between 11.65 g of 2-(butylthio)vinylphosphonic dichloride, 6.5 g of butyl alcohol, and 8 g of pyridine gave 11 g of ester, b.p.153-154° (2 mm); n_D^{20} 1.4848; d_4^{20} 1.0235.

Found %: C 54.06; 54.15; H 9.27; 9.30

$C_{14}H_{29}PSO_3$. Calculated %: C 54.54; H 9.41

Diallyl 2-(Butylthio)vinylphosphonate n-$C_4H_9SCH=CHPO(OC_3H_5)_2$. This ester (9 g) was obtained by reaction between 6 g of allyl alcohol and 11.7 g of 2-(butylthio)vinylphosphonic dichloride in presence of 8.3 g of pyridine in a benzene medium. It had b.p.146° (1 mm); n_D^{20} 1.5049; d_4^{20} 1.0800.

Found %: P 11.23; 11.13

$C_{12}H_{21}PO_3S$. Calculated %: P 11.29

Dihexyl 2-(Butylthio)vinylphosphonate n-$C_4H_9SCH=CHPO(OC_6H_{13}\text{-}n)_2$. 2-(Buthylthio)vinylphosphonic dichloride (11.65 g) was added to a stirred mixture of 10.2 g of hexyl alcohol and 8 g of pyridine. The resulting ester (12.5 g) had b.p.201° (2 mm); n_D^{20} 1.4790; d_4^{20} 1.0009.

Found %: P 8.48; 8.53

$C_{18}H_{37}PO_3S$. Calculated %: P 8.51

SUMMARY

The following compounds were prepared and characterized: 2-(ethylthio)vinylphosphonic and 2-(butylthio)vinylphosphonic dichlorides; dipropyl, dibutyl, diallyl, dihexyl, bis(2-methoxyethyl), and bis(2-ethoxyethyl) 2-(ethylthio)vinylphosphonates; dibutyl, diallyl, and dihexyl 2-(butylthio)vinylphosphonates; and 2-(ethylthio)vinylphosphonic dipiperidide.

REACTIONS OF ORGANOMERCURY BASES WITH UNSATURATED COMPOUNDS •

I. F. Lutsenko and E. I. Yurkova

Organomercury bases and their reactions have received relatively little study. It is known that organomercury hydroxides are readily arylated by aromatic compounds of tin, antimony, and boron with formation of unsymmetrical mercury compounds of the type RHgR' [1] and that they have found application as mercurating agents, being among the most powerful known [2]. In recent years, Razuvaev and coworkers have made extensive investigations into the mechanism of the photochemical decomposition of arylmercury hydroxides and the behavior of the resulting radicals in solvents having various dielectric constants [3]. Arylmercury hydroxides, however, can react not only by the radical mechanism, but also by an ionic mechanism, which is associated with the dissociation:

$$RHgOH \rightleftharpoons RHg^{+} + OH^{-}.$$

It is probable that organomercury bases react in this form also in the recently discovered reaction between moist mercuric oxide and a vinyl ether [4], which gives compounds in which a mercury atom is substituted into two molecules of a carbonyl compound:

$$HgO + H_2O + CH_2 = CHOR \longrightarrow \left[HOHgCH_2CH\begin{matrix}OR\\OH\end{matrix}\right] \xrightarrow{CH_2 = CHOR} Hg(CH_2CHO)_2.$$

The intermediately formed (hydroxymercury) acetaldehyde adds to a further molecule of the vinyl ether and yields the full organomercury compound. If the scheme proposed for the course of the reaction is correct then it may be expected that other organomercury bases will add at carbon-carbon double bonds.

We therefore investigated the behavior of phenyl- and p-tolyl-mercury hydroxides toward some unsaturated hydrocarbons (1-hexene, 1-heptene, cyclohexene, styrene, and 1,1-diphenylethylene), vinyl ethers (ethyl vinyl, isopropyl vinyl, butyl vinyl, and ethyl isopropenyl ethers), and ketene diethyl acetal.

Attempts to bring about the addition of arylmercury hydroxides to α-olefins in accordance with the scheme

$$ArHgOH + RCH = CH_2 \xrightarrow{CH_3OH} \begin{matrix}RCH - CH_2HgAr\\|\\OCH_3\end{matrix}$$

were not successful; treatments were carried out both in the cold, and also at the boil (45 minutes in a water bath), in all of the experiments, the arylmercury hydroxide was recovered in yields of more than 90%.

Hence, in these α-olefins of various structure the double bond was found to be inert toward arylmercury hydroxides. On the other hand, vinyl ethers, in which the double bond is more active, react readily even in the cold with a methanol solution of an arylmercury hydroxide. On the basis of the considerations given in the previous paper [4], it may be expected that this reaction will result in the formation of a full unsymmetrical organomercury compound in accordance with the following equation:

$$ArHgOH + CH_2 = CHOR \xrightarrow{CH_3OH} ArHgCH_2CH\begin{matrix}OR\\OCH_3\end{matrix}$$

In all of the experiments on the various vinyl ethers we were unable to isolate the mixed acetal of the (arylmercuri)acetaldehyde, a result that is probably to be associated with the extreme lability of compounds of this type.

• Communication from A. N. Nesmeyanov's laboratory

It is well known that full organomercury compounds of the type RHgR' are unstable, undergoing decomposition even at ordinary temperature into a mixture of the two symmetrical compounds R_2Hg and R'_2Hg. For the mixed acetal of an (arylmercuri) acetaldehyde this process must occur particularly readily as the result of the presence of a labile C—Hg bond, which is ruptured already by 0.25 N HCl. As a result of the disproportionation, the mixed acetal of the (arylmercuri) acetaldehyde should yield two compounds — a diarylmercury and a mixed acetal of mercuridiacetaldehyde:

$$2ArHgCH_2CH\begin{matrix}OR\\OCH_3\end{matrix} \longrightarrow Ar_2Hg + Hg\left(CH_2CH\begin{matrix}OR\\OCH_3\end{matrix}\right)_2.$$

It was in fact found that in all of the investigated reactions between arylmercury hydroxides and vinyl ethers the diarylmercury was obtained in almost quantitative yield. Considerable difficulties were encountered in the isolation of the second reaction product — the mixed acetal of mercuridiacetaldehyde — since it is a heavy oil, readily decomposed by heat so that it cannot be purified by distillation. It must be pointed out that diarylmercury is appreciably soluble in this oil, which made it still more difficult to isolate the second reaction product and prove its structure. As all attempts to isolate the mixed acetal of mercuridiacetaldehyde in an analytically pure form failed, the formation of this compound was proved by the following two reactions. The oil remaining after separation of the bulk of the diarylmercury was dissolved in alcohol and the solution was mixed with an alcoholic solution of mercuric chloride. The (chloromercuri) acetaldehyde that separated was characterized by analysis and by a mixture melting test with an authentic sample. The separation of (chloromercuri)acetaldehyde instead of its mixed acetal is to be attributed to the hydrolysis of the latter by hydrogen chloride formed in the alcoholysis of the mercuric chloride. The reaction can be represented as follows:

$$Hg\left(CH_2CH\begin{matrix}OR\\OCH_3\end{matrix}\right)_2 + HgCl_2 \xrightarrow{CH_3OH-H_2O} 2ClHgCH_2CHO + ROH + CH_3OH.$$

The formation of a mixed acetal of mercuridiacetaldehyde by reaction of an arylmercury hydroxide with a vinyl ether can be proved also by hydrolysis of the acetal and isolation of mercuridiacetaldehyde. It is in fact found that, when an alcoholic solution of the unpurified mixed acetal of mercuridiacetaldehyde (remaining after separation of the diarylmercury) is boiled with traces of hydrochloric acid, the acetal is hydrolyzed and mercuridiacetaldehyde — characterized by analysis and by a mixture melting test with an authentic sample — is obtained in high yield. In an analogous way, reaction between phenylmercury hydroxide and ethyl isopropenyl ether yielded diphenylmercury and mercuridiacetone.

The addition reaction between an arylmercury hydroxide and a vinyl ether can be used preparatively for the symmetrization of organomercury salts under very mild conditions. In this reaction there is no need to isolate the arylmercury hydroxide obtained by boiling an organomercury salt with methanolic caustic potash; this fact is shown by the reactions of phenyl- and p-tolyl-mercury chlorides with vinyl ethers in an alkaline medium. It would appear that this method can be used for the symmetrization of products formed by the addition of mercury salts at a double bond, a process that cannot be effected by the use of the usual symmetrizing agents (both reducing agents and complex-forming agents).

Ketene diethyl acetal, which contains an extremely active double bond, reacts with phenylmercury hydroxide with evolution of an appreciable amount of heat. From the reaction mixture we isolated diphenylmercury in high yield. Hence, by analogy with the reaction of an arylmercury hydroxide with a vinyl ether, considered above, it must be supposed that the intermediately formed ethyl (phenylmercuri) acetate is unstable and decomposes into diphenylmercury and diethyl mercuridiacetate. The whole process can be represented as follows:

$$CH_2=C(OC_2H_5)_2 + C_6H_5HgOH \longrightarrow \left[C_6H_5HgCH_2C\begin{matrix}OC_2H_5\\OC_2H_5\\OH\end{matrix}\right] \longrightarrow$$

$$\xrightarrow{-C_2H_5OH} \left[C_6H_5HgCH_2C\begin{matrix}O\\OC_2H_5\end{matrix}\right] \longrightarrow (C_6H_5)_2Hg + Hg\left(CH_2C\begin{matrix}O\\OC_2H_5\end{matrix}\right)_2.$$

It was not found possible to isolate the diethyl mercuridiacetate from the oily readily decomposed residue remaining after separation of diphenylmercury. However, when an alcohol solution of mercuric chloride was added

to this oily residue, a low yield was obtained of a crystalline compound corresponding in analysis to the expected ethyl (chloromercuri) acetate. It was thus shown that organomercury bases are able to add at the double carbon-carbon bond of a vinyl ether or of ketene diethyl acetal.

EXPERIMENTAL

Reaction of Phenylmercury Hydroxide with Ethyl Vinyl Ether. Ethyl vinyl ether (2 g) was added to a filtered solution of 3 g (0.01 mole) of phenylmercury hydroxide in 140 ml of methanol. On the next day the solution was evaporated down to two-thirds bulk under reduced pressure. The diphenylmercury that separated was filtered off at the pump. The yield was 1.7 g (94%). The substance had m.p. 118-120°, undepressed by admixture of authentic diphenylmercury.

Found%: Hg 56.55; 56.41
$(C_6H_5)_2Hg$. Calculated%: Hg 56.50

Methanol was driven from the filtrate under reduced pressure, and the oil that remained was dissolved in an equal volume of alcohol and added to an alcoholic solution of 1.8 g of mercuric chloride. The mixture was heated for a short time and cooled; the precipitate of phenylmercury chloride was filtered off. It had m.p. 252-253°, undepressed by admixture of an authentic sample.

The remaining solution was completely freed from alcohol under reduced pressure. The crystalline precipitate that formed was found to be (chloromercuri)acetaldehyde, amounting to 0.9 g (75%).. After crystallization from dichloroethane it had m.p. 128-129°, undepressed by admixture of an authentic sample.

Found%: Hg 71.50; 71.75
$ClHgCH_2CHO$. Calculated%: Hg 71.88

Reaction of Phenylmercury Hydroxide with Ethyl Vinyl Ether. Isolation of Mercuridiacetaldehyde. Under similar conditions a solution of 6 g of phenylmercury hydroxide was brought into reaction with 4 g of ethyl vinyl ether. The yield of diphenylmercury was quantitative; it had m.p. 120-122°. The oil remaining after separation of diphenylmercury was dissolved in an equal volume of alcohol, and the solution was acidified with a drop of concentrated hydrochloric acid (as little as possible of the acid must be taken), heated to the boil, filtered, and set aside to crystallize. Crystals of mercuridiacetaldehyde formed, and were separated and washed with absolute ether. The yield was 0.8 g (66%). The substance melted at 92-93° and there was no depression in admixture with mercuridiacetaldehyde prepared from mercuric oxide and ethyl vinyl ether.

Found%: Hg 69.75; 69.91
$Hg(CH_2CHO)_2$. Calculated%: Hg 69.97

Reactions of Phenylmercury Hydroxide with Butyl Vinyl Ether and with Isopropyl Vinyl Ether. Reaction, under the conditions described above, between 3 g (0.01 mole) of phenylmercury hydroxide and 2 g of butyl vinyl ether yielded 1.7 g (94%) of diphenylmercury, m.p. 120°, and 0.9 g (75%) of mercuridiacetaldehyde, m.p. 92-93°.

Found%: Hg 69.73; 69.82
$Hg(CH_2CHO)_2$. Calculated%: Hg 69.97

The same results were obtained when butyl vinyl ether was replaced by isopropyl vinyl ether.

Reactions of p-Tolylmercury Hydroxide with Ethyl Vinyl and Butyl Vinyl Ethers. Ethyl vinyl ether (2 g) was added to a filtered solution of 3.1 g (0.01 mole) of p-tolylmercury hydroxide in 120 ml of methanol. On the next day one-third of the solvent was removed under reduced pressure, and the di-p-tolylmercury that separated was filtered off. The yield was 1.7 g (90%). The substance melted at 237-238°.

Found%: C 43.23; H 3.75; Hg 51.60
$(C_7H_7)_2Hg$. Calculated%: C 43.90; H 3.66; Hg 52.35

Mercuridiacetaldehyde, m.p. 92-93°, was isolated from the filtrate in the way described above. There was no depression in a mixture melting test.

Found%: Hg 69.90
$Hg(CH_2CHO)_2$. Calculated%: Hg 69.97

Similar results were obtained also in the reaction of p-tolylmercury hydroxide with butyl vinyl ether.

Symmetrization of Phenylmercury Chloride. Caustic potash, as a 40% methanolic solution (26.5 ml), was added to a solution of 5 g of phenylmercury chloride in 100 ml of methanol, and the mixture was boiled for 30 minutes. The mixture was cooled and filtered, and 1.5-2 g of ethyl vinyl ether was added to the filtrate. On the next day one-third of the solvent was distilled off, and the diphenylmercury that separated was filtered off. The yield was 2.6 g (92%). It had m.p. 119-120°, undepressed by admixture of authentic diphenylmercury.

Found%: Hg 56.46; 56.41
$(C_6H_5)_2Hg$. Calculated%: Hg 56.50

Symmetrization of p-Tolylmercury Chloride. Reaction, under similar conditions, between 5 g of p-tolylmercury chloride and 2 g of ethyl vinyl ether yielded 2.7 g (95%) of di-p-tolylmercury, m.p. 237-238°.

Found%: Hg 52.23; 52.32
$(C_7H_7)_2Hg$. Calculated%: Hg 52.35

Reaction of Phenylmercury Hydroxide with Ethyl Isopropenyl Ether. Ethyl isopropenyl ether (1 g) was added to a solution of 1 g of phenylmercury hydroxide in 50 ml of methanol. The further treatment was as described above, and a quantitative yield of diphenylmercury, m.p. 118-120°, was obtained.

Found%: Hg 56.44; 56.54
$(C_6H_5)_2Hg$. Calculated%: Hg 56.50

The oil remaining after the separation of diphenylmercury was acidified with a drop of hydrochloric acid, and mercuridiacetone, amounting to 0.25 g (45%), was isolated. It had m.p. 67-68°, undepressed by admixture of an authentic sample.

Found%: Hg 63.70
$Hg(CH_2COCH_3)_2$. Calculated%: Hg 63.74

Reaction of Phenylmercury Hydroxide with Ketene Diethyl Acetal. Phenylmercury hydroxide, amounting to 3 g (0.01 mole), was added gradually to 3 g of ketene diethyl acetal. Reaction set in immediately with evolution of some heat, and the whole of the phenylmercury hydroxide dissolved. On the next day a ten-fold amount of absolute ether was added to bring about the separation of the polymer of ketene diethyl acetal. The polymer was filtered off, and two-thirds of the ether was evaporated off. The diphenylmercury that separated was filtered off and washed with ether. The yield was 1.6 g (88%). It had m.p. 118-120°, undepressed by admixture of an authentic sample.

Found%: Hg 56.54; 56.50
$(C_6H_5)_2Hg$. Calculated%: Hg 56.50

Ether was completely removed from the mother liquor under reduced pressure, and the oil so obtained was dissolved in an equal volume of methanol and added to a solution of 1.6 g of mercuric chloride in 20 ml of alcohol. Crystals of phenylmercury chloride separated and were filtered off; m.p. 252-253°. Methanol was completely removed from the filtrate under reduced pressure. From the oily residue chloroform precipitated a mixture of ethyl (chloromercuri)acetate and mercurous salts. This material was extracted with acetone, and evaporation of the extract yielded ethyl (chloromercuri)acetate, m.p. 64-66°.

Found%: Hg 61.79
$ClHgCH_2COOC_2H_5$. Calculated%: Hg 62.08

SUMMARY

1. It was shown that arylmercury hydroxides do not react with unsaturated hydrocarbons.

2. Arylmercury hydroxides react with vinyl ethers with formation of the diarylmercury together with mercuridiacetaldehyde or a mercuridialkanone. The reaction can be applied as a new method for the symmetrization of organomercury salts under mild conditions; it gives almost quantitative yields of diarylmercury.

3. Arylmercury hydroxides readily react with ketene diethyl acetal with formation of the diarylmercury and mercurated ethyl acetate.

SYNTHESIS OF POLYCYCLIC COMPOUNDS RELATED TO STEROIDS

COMMUNICATION 36. CONDENSATION OF CYCLIC SATURATED KETONES WITH α,β-UNSATURATED CYCLIC KETONES

I. N. Nazarov, S. I. Zavyalov, and M. S. Burmistrova

In our laboratory we have recently [1] developed convenient methods for the preparation of α,β-unsaturated cyclic ketones, which we have used in numerous diene condensations and so have synthesized a variety of polycyclic compounds related to steroids. It was considered to be of interest to study also the Michael condensation of α,β-unsaturated cyclic ketones with saturated ketones with the object of preparing polycyclic ketones of the bicyclohexyl and cyclopentylcyclohexane series according to the schemes indicated:

As is well known, these classes of compounds include some synthetic estrogens, for example the tricyclic ketones (I) [3] and (II) [4].

It was found that these condensations occur in quite satisfactory yields at room temperature in presence of one-third of an equivalent of potassium in a medium of tert-butyl alcohol and dioxane.

Reaction of 2-methyl-2-cyclohexen-1-one (IV) with 3,4-dihydro-6-methoxy-1(2H)-naphthalenone (III) gave about a 50% yield of a crystalline ketone which corresponded in elementary analysis and chemical properties to the normal condensation product (V).

At 340-350° the diketone (V) decomposed into its original components, and when heated in the cold with excess of acetone cyanohydrin in presence of piperidine a 70% yield of the monocyanohydrin (VII) was formed (see scheme on top of following page); which is in accord with the known inertness of the carbonyl group of 3,4-dihydro-1(2H)-naphthalenone toward acetone cyanohydrin [5]. It is interesting to note that with excess of semicarbazide the diketone (V) again gives only a mono-derivative (VIII), the structure of which must be analogous to that of the monocyanohydrin (VII).

Demethylation of the diketone (V) with aluminum chloride in boiling xylene gave a 40% yield of the corresponding phenol (VI), which could be reconverted into the diketone (V) by the action of diazomethane.

Although the phenol (VI) is very similar structurally to the physiologically active compounds (I) and (II), it showed no estrogenic activity when tested on rats.

It was found that 2-methyl-2-cyclopenten-1-one (IX) also combined with 3,4-dihydro-6-methoxy-1(2H)-naphthalenone, the product being the diketone (X), which was characterized as the monosemicarbazone:

When the diketone (X) was demethylated with the aid of aluminum chloride in xylene or hydrogen bromide in acetic acid, the product was a phenolic oil which we could not crystallize.

Condensation of cyclohexanone with 2-methyl-2-cyclohexen-1-one resulted in the formation of 2'-methyl-[bicyclohexyl]-2,3'-dione (XI), which, unlike the above-described condensation products (V) and (X), readily gave a disemicarbazone:

EXPERIMENTAL

Condensation of 3,4-Dihydro-6-methoxy-1(2H)-naphthalenone with 2-Methyl-2-cyclohexen-1-one. A solution of 6.8 g of 3,4-dihydro-6-methoxy-1(2H)-naphthalenone (III) (b.p. 135-138°/12 mm, m.p. 78-79°) [6] in 20 ml of dioxane was added to a stirred solution of potassium tert-butoxide prepared by dissolving 0.4 of potassium in 10 ml of tert-butyl alcohol, and then dropwise addition was made of 4.4 g of 2-methyl-2-cyclohexen-1-one (IV) (b.p. 56-57°/9 mm, n_D^{20} 1.4865. [1]. The mixture was set aside for three hours at room temperature and was then neutralized to Congo red with concentrated hydrochloric acid and evaporated to dryness under reduced pressure. The residue was treated with water and extracted with ether. Vacuum fractionation of the reaction product yielded 1 g of unchanged 3,4-dihydro-6-methoxy-1(2H)-naphthalenone and 7 g of an oil boiling at 200-215° (1 mm). Addition of ether to this oil precipitated the diketone (V), m.p. 115-116° (from aqueous methanol). The yield was 5 g (53% on the amount of the 3,4-dihydro-6-methoxy-1(2H)-naphthalenone that reacted).

	Found %:	C 75.12; 75.10; H 7.80; 7.94
$C_{18}H_{22}O_3$.	Calculated %:	C 75.4; H 7.7

After being washed with methanol, the monosemicarbazide melted with decomposition at 237-238°.

Found%: N 11.81; 11.89
$C_{19}H_{25}O_3N_3$. Calculated%: N 12.2

Thermal Decomposition of the Diketone (V). The above-described diketone (V) (0.5 g) was heated at 340-350° until distillation ceased (10-15 minutes). The distillate solidified almost completely. The product isolated was 0.1 g (33%) of 3,4-dihydro-6methoxy-1(2H)-naphthalenone (III).

Demethylation of the Diketone (V). A stirred mixture of 0.5 g of the diketone (V), 1 g of aluminum chloride, and 10 g of dry xylene was boiled for seven minutes. The reaction mixture was cooled and decomposed by addition of ice and dilute (1:1) hydrochloric acid. The precipitate that formed was dissolved in dilute caustic soda (2-5%), and after filtration of the solution the substance was reprecipitated with dilute hydrochloric acid. The product was 0.2 g (40%) of the monohydrate of the phenol (VI), m.p. 196-198° (from aqueous methanol).

Found%: C 70.43; 70.45; H 7.60; 7.63
$C_{17}H_{22}O_3H_2O$. Calculated%: C 70.4; H 7.6

After being washed with methanol, the monosemicarbazide melted with decomposition at 247-248°.

Found%: N 13.14; 13.25
$C_{18}H_{25}O_3N_3$. Calculated%: N 12.8

Treatment of the phenol (VI) with diazomethane in ether converted it into the original diketone (V).

Preparation of the Cyanohydrin of the Diketone (V). A mixture of 0.3 g of the diketone (V), 0.5 g of acetone cyanohydrin, one drop of piperidine, and 10 ml of ether was allowed to stand for one day at room temperature. The product isolated was 0.2 g of the cyanohydrin (VII), m.p. 165-168°. The mother liquor was evaporated to dryness under reduced pressure, and 0.5 g of acetone cyanohydrin and 10 ml of ether were added to the residue. After a time a further 0.05 g of the cyanohydrin (VII) was precipitated, the total yield being 0.25 g (70%).

Found%: C 73.00; 73.04; H 7.43; 7.60; N 4.61; 4.65
$C_{15}H_{23}O_3N$. Calculated%: C 72.8 H 7.4; N 4.5

Condensation of 3,4-Dihydro-6-methoxy-1(2H)-naphthalenone with 2-Methyl-2-cyclopenten-1-one. The procedure was the same as for the condensation with 2-methyl-2-cyclohexen-1-one. Reaction of 7 g of 3,4-dihydro-6-methoxy-1(2H)-naphthalenone with 4.2 g of 2-methyl 2-cyclopenten-1-one (IX) (b.p. 52-53°/15 mm, n_D^{20} 1.4470) [1] yielded 4 g of the diketone (X), b.p. 195-201° (1.5 mm), n_D^{20} 1.5660. When the amount (1.9 g) of unchanged 3,4-dihydro-6-methoxy-1(2H)-naphthalenone was taken into account, it was found that the yield of the diketone (X) was 51%.

Found%: C 74.74; 74.6; H 7.44; 7.49
$C_{17}H_{20}O_3N_3$. Calculated%: C 75.0 H 7.3

After being washed with methanol, the monosemicarbazide melted at 217-218°.

Found%: N 12.56; 12.36
$C_{21}H_{23}O_3N_3$. Calculated%: N 12.8

Demethylation of the Diketone (X). A mixture of 0.5 g of the diketone (X) and 10 ml of a solution, saturated at 70°, of hydrogen bromide in glacial acetic acid was heated at 65-70° for five hours. The solution was evaporated to dryness under reduced pressure. The residue was dissolved in dilute alkali, the solution was filtered, and the reaction product was precipitated with dilute hydrochloric acid. The product was 0.3 g of a viscous noncrystallizing oil of phenolic character.

When the demethylation of the diketone (X) was effected with the aid of aluminum chloride in xylene, we were again unable to isolate a crystalline phenol.

Condensation of Cyclohexanone with 2-Methyl-2-cyclohexen-1-one. The condensation was carried out in the manner described above. Reaction between 2 g of cyclohexanone and 2.2 g of 2-methyl-2-cyclohexen-1-one yielded 2.5 g (59%) of 2'-methyl-[bicyclohexyl]-2,3'-dione (XI), b.p. 142-145° (1.5 mm), n_D^{20} 1.5115

Found%: C 74.62; 74.56; H 9.48; 9.66
$C_{13}H_{20}O_2$. Calculated%: C 74.9 H 9.6

After being washed with methanol, the disemicarbazide melted at 237-238° (with decomposition).

Found%: N 25.72; 25.50

$C_{18}H_{26}O_2N_6$. Calculated%: N 26.1

In conclusion we express our thanks to Prof. M. D. Mashkovsky for estrogenic-activity tests on the diketone (VI).

SUMMARY

[1] Diketones of the bicyclohexyl and cyclopentylcyclohexane series were synthesized by the Michael condensation of cyclic ketones with α,β-unsaturated cyclic ketones.

[2] When 3,4-dihydro-6-methoxy-1-(2H)-naphthalenone (III) was condensed with 2-methyl-2-cyclohexen-1-one (IV) and with 2-methyl-2-cyclopenten-1-one (IX) in presence of potassium tert-butoxide in tert-butyl alcohol and dioxane, the respective products, obtained in about 50% yield, were the diketones (V) and (X). Condensation cyclohexanone with 2-methyl-2-cyclohexen-1-one gave the diketone (XI) in 59% yield.

HYDROGENATION OF ISOPROPENYLCYCLOPROPANE IN PRESENCE OF PALLADIUM BLACK

B. A. Kazansky, M. Yu. Lukina, A. I. Malyshev, V. T. Aleksanyan, and Kh. E. Sterin

As we wished to study the physical properties and chemical behavior of alkylcyclopropanes having a branched side chain, we decided to synthesize such compounds from the corresponding tertiary alcohols of the cyclopropane series. Such alcohols are readily prepared from alkyl cyclopropyl ketones, and they readily give the corresponding alkenylcyclopropanes by dehydration, for example:

We hoped that we should be able to obtain the required alkylcyclopropanes by hydrogenating the double bond of unsaturated hydrocarbons obtained in this way, but our attempts to hydrogenate one of these compounds— isopropenylcyclopropane — in presence of palladium black at ordinary temperature and pressure did not give the desired result: addition of two molecules of hydrogen occurred with formation of 2-methylpentane. The formation of this paraffin — product of the hydrogenolysis of the three-membered ring at the bond adjacent to the substituent — stands in conflict with several reported experimental facts relating to the hydrogenolysis of alkylcyclopropanes. Thus, Kizhner [1], and later Rozanov [2], found that in the hydrogenolysis of alkylcyclopropanes over nickel at 150° in a flow system, hydrogen adds at the bond lying opposite to the carbon carrying the substituent, or, in more general terms, hydrogen adds to the most hydrogenated carbon atoms.

In our investigations [3, 4] on the catalytic hydrogenation of alkylcyclopropanes in the vapor phase at atmospheric pressure in presence of platinized charcoal, this law was fully confirmed. It was confirmed also in the investigations of Boord and coworkers [5], who carried out the hydrogenolysis of alkylcyclopropanes over a nickel catalyst under different conditions, the hydrogen being under pressure. It should be noted these authors hold the view — which is contrary to our observations [4] — that the three-membered cycle has considerable stability, fairly severe conditions being required for the rupture of C—C linkages of the ring. For example, they carried out the hydrogenolysis of isopropylcyclopropane (with formation of 2,3-dimethylbutane) at 150-200° and 87 atm. However, in an attempt to hydrogenate the double bond of isopropenylcyclopropane selectively under milder conditions (37°, 56 atm), these authors obtained isopropylcyclopropane together with an appreciable amount of 2-methylpentane. In explanation of this fact they suggested that the formation of the second substance was due to the conjugation of the double bond of isopropenylcyclopropane with the three-membered ring; this suggestion was not checked experimentally. Later, Slabey [6] showed that by the use of baryta-promoted copper chromite catalyst at 100-130° and 105-140 atm it is possible to hydrogenate the double bond of isopropenylcyclopropane without touching the C—C bonds of the ring.

Having obtained 2-methylpentane by the hydrogenation of isopropenylcyclopropane in presence of palladium, we considered it essential to determine the cause of the anomalous course of the reaction. We decided, therefore, to isolate the intermediate hydrogenation products, carrying out the reaction under the same conditions but interrupting it as soon as the absorption of one molecular proportion of hydrogen was complete. The results of the fractionation of the catalyzate led us to suppose that the mixture contained not only isopropane and 2-methylpentane, but also 2-methylpentenes. However, the components of the mixture were so similar in boiling point that we were unable to isolate them in pure state. We therefore determined the composition of the catalyzate from Raman spectra.

The spectrum of isopropenylcyclopropane was not known, and the data in the literature on the spectra of 2-methyl-1-pentene and 2-methyl-2-pentene [7, 8] did not appear to be sufficiently reliable. It was therefore necessary to synthesize the last two hydrocarbons and to determine the spectra of all three compounds, expressing the intensities of the lines in the accepted cyclohexane scale. It was indeed found that, for example, in 2-methyl-1-pentene the frequency of the double bond is 1650 cm^{-1}, and not 1663 cm^{-1} [8]. Investigation of the spectra of the catalyzate showed that the mixture of hydrocarbons obtained as a result of incomplete hydrogenation consisted

of unchanged isopropenylcyclopropane, 2-methyl-2-pentene, and, in smaller amount, 2-methyl-1-pentene. In addition, a small amount of 2-methylpentane was found. No isopropylcyclopropane could be detected in the catalyzate by spectrum analysis. This indicates that the double bond of isopropenylcyclopropane does not undergo selective hydrogenation, the final reaction product – 2-methylpentane – being formed by the hydrogenation of 2-methylpentenes formed as intermediate products. The formation of 2-methylpentenes can readily be explained when we regard isopropenylcyclopropane as a conjugated system in which the three-membered ring is conjugated with the double bond.

The formation of 2-methyl-2-pentene could then be either the result of the hydrogenolysis of the three-membered ring at a bond adjacent to the substituent, i.e. 3,4-addition of hydrogen with subsequent partial isomerization of the resulting 2-methyl-1-pentene into 2-methyl-2-pentene:

or the result of 1,4-addition of hydrogen:

In order to determine the mechanism with greater precision it was necessary to check whether or not the isomerization of 2-methylpentenes with displacement of the double bond from position 1 to 2 and vice versa actually occurs under the hydrogenation conditions. We therefore took our synthetic 2-methyl-1-pentene and 2-methyl-2-pentene and shook them with palladium black, shaking being stopped when only 0.2 of a molecular proportion of hydrogen had been absorbed so that olefins formed by double-bond displacement should, in the main, be preserved in the catalyzate. These experiments showed that, under such conditions, these methylpentenes do in fact isomerize into one another, giving mixtures of 2-methyl-2-pentene and 2-methyl-1-pentene identical in composition, the first compound predominating.

As a special experiment showed, isopropenylcyclopropane itself is not isomerized when its alcoholic solution is shaken with reduced palladium black.

The above facts enable us to conclude that, in hydrogenation under the conditions described above, conjugation does indeed occur between the double bond and the three-membered cycle in isopropenylcyclopropane with consequent weakening of the C–C bond of the ring which is adjacent to the substituent. The fact that isopropylcyclopropane is not formed, or is formed only in insignificant amount, in the hydrogenation of isopropenylcyclopropane indicates that hydrogen adds more readily to a three-membered ring conjugated with a double bond than to the double bond itself.

EXPERIMENTAL

Isopropenylcyclopropane was prepared by the dehydration of 1-cyclopropyl-1-methylethanol with the aid of a few drops of concentrated sulfuric acid. After distillation through a column the hydrocarbon had b.p. 70.5° (760 mm); n_D^{20} 1.4255; d_4^{20} 0.7517 •.

$\Delta\nu$ (cm^{-1}): 234 (2 b), 268 (36 b), 294 (0), 315 (1), 343 (0), 359 (0), 394 (16), 415 (27), 474 (55, sh), 587 (18 diff. background) 531 (12), 695 (12), 714 (41, sh), 729 (19), 797 (6), 818 (25, b), 890 (60), 900 (30, b) 933 (0), 932 (37), 995 (9, sh) 1020 (17) 1035 (3), 1049 (3, dif), 1089 (15, dif), 1100 (14, dif), 1169 (3, dif), 1192 (110, b, doublet), 1225 (5, dif), 1238 (6 dif) 1293 (16 sh), 1318 (2), 1340 (4, dif), 1369 (4, dif), 1391 (50, b, doublet), 1403 (10, background), 1428 (64, background), 1459 (43 background), 1503 (2), 1635 (114, sh), 1649 (90, sh), 2854 (10, background) 2870 (10, background), 2898 (20 dif), 2917 (45, sh), 2938 (10, background), 2973 (20 dif), 2988 (60, sh), 3013 (140, b, doublet), 3083 (60, b, doublet).

2-Methyl-1-pentene was prepared in admixture with 2-methyl-2-pentene by the dehydration of 2-

• Data from the literature was given in Table 1 for all of the hydrocarbons synthesized.

methyl-2-pentanol with the aid of iodine. The hydrocarbons were separated by distillation through a 100-plate laboratory column.

2-Methyl-1-pentene: b.p. 61.4° (760 mm); n_D^{20} 1.3918; d_4^{20} 0.6802.

The Catalyst was palladium black, prepared from palladium chloride by Zelinsky's method [9].

Hydrogenation was carried out at 18-20° in a 100-ml hydrogenation flask of the usual type. Distilled ethanol (40 ml for each experiment) and electrolytic hydrogen were used, and a fresh portion of catalyst (0.4 g) was taken for each experiment. The hydrogenation product was distilled off as an azeotropic mixture with alcohol through a column having a glass packing; it was then washed, dried, and fractionated through a 40-plate column having a copper packing. In all fractionations 7 ml of heptane (n_D^{20} 1.3877), was added as a displacing agent.

Isomerization was carried out under the same conditions as hydrogenation. In the case of isopropenylcyclopropane it was carried out in absence of hydrogen, and in the case of the methylpentenes it was carried out in presence of hydrogen, 20% of the amount necessary for hydrogenation being allowed to add. The catalyzate was separated as in the case of hydrogenation.

TABLE 1

Hydrocarbon	B.p. (°C,760 mm)	n_D^{20}	d_4^{20}
Isopropenylcyclopropane [6]	70.33	1.42550	0.75153
Isopropylcyclopropane [6]	58.37	1.38639	0.69829
2-Methylpentane [10]	60.271	1.37145	0.65315
2-Methyl-2-pentene [10]	67.29	1.4004	0.6863
2-Methyl-1-pentene [10]	60.7	1.3915	0.6817

Data from the literature on isopropenylcyclopropane and hydrocarbons that can be obtained when it is hydrogenated are given in Table 1.

Hydrogenation

Experiment 1. The isopropenylcyclopropane (11.5 g, i.e. 15.4 ml) absorbed 6230 ml of hydrogen *. The theoretical amount of hydrogen, corresponding to the addition of two molecular proportions, is 6270 ml. The catalyzate amounted to 11.2 g (17.1 ml). The fractionation results are given in Table 2.

On the basis of the constants given in Table 2, the product of the addition of two molecular proportions of hydrogen to isopropenylcyclopropane is 2-methylpentane.

Experiment 2. The amount of isopropenylcyclopropane taken was 18.2 g (24.4 ml), the theoretical two molecular proportions of hydrogen being 9930 ml. The amount of hydrogen that added was 5500 ml, i.e. somewhat more than one molecular proportion, and 16.3 g (23.8 ml) of catalyzate was obtained. The results of the

* In all experiments the volume of hydrogen is adjusted to normal conditions.

fractionation are given in Table 3.

Losses	—	1.1			

On the basis of the data in Table 3, the catalyzate may contain all of the hydrocarbons listed in Table 1. Fractions V-VII consist essentially of 2-methyl-2-pentene.

Experiment 3. The amount of isopropenylcyclopropane taken was 22.3 g (30.0 ml), which theoretically requires 12.160 ml of hydrogen for complete hydrogenation. The amount that actually added was 6070 ml, and 20.8 g (31.0 ml) of catalyzate was obtained. The fractionation results are given in Table 4 and Fig. 1.

TABLE 4

Fraction	Amount (ml)	Amount (g)	B.p. (°C, 760 mm)	n_D^{20}	d_4^{20}
I	2.5	1.6	58.0–60.0	1.3855	0.6668
II	6.0	4.0	60.0–62.1	1.3882	0.6735

VI	4.0	3.0	67.4–69.8	1.4108	0.7181
Losses		0.8			

As in Experiment 2, mixtures of hydrocarbons were obtained with a predominance of 2-methyl-2-pentene in Fractions IV and V. In order to isolate 2-methyl-2-pentene in a purer state, Fractions V-VII from Experiment 2 and Fractions IV and V from Experiment 3 were combined and refractionated through a column. Altogether, 15.0 g (21.6 ml) of hydrocarbon mixture was taken for fractionation. The results of the fractionation are given in Table 5.

Fractions II and III, according to their constants, are 2-methyl-2-pentene. For analysis with the aid of Raman spectra the following samples are used:

Sample I (6.0 g) - a mixture of Fractions I-IV from Experiment 2 (see Table 3).

Sample II (12.3 g) - a mixture of Fractions I-III from Experiment 3 (see Table 4) and Fraction I from the refractionation (see Table 5).

Sample III (5.9 g) - a mixture of Fractions II and III from the refractionation (see Table 5).

Sample IV (8.1 g)– a mixture of Fraction IX from Experiment 2 (see Table 3), Fraction VI from Experiment 3 (see Table 4), and the residue from the refractionation (see Table 5).

Fig. 1. Fractionation curve of the catalyzate from Experiment 3.

The Raman spectra of Samples II, III and IV are given in Fig. 2; the spectrum of Sample I differed little from that of Sample II and is therefore not given. On the basis of the spectrographic investigation of Samples I-IV, the following tentative values were calculated for the contents of hydrocarbons in the catalysis products:

2-Methyl-1-pentene	~ 30%
2-Methyl-2-pentene	~ 50%
Isopropenylcyclopropane	~ 8%
2-Methylpentane	~ 12%

We hope to obtain more precise values in a further investigation.

Isomerization

Experiment 1. Shaking of 15.0 g (20.0 ml) of isopropenylcyclopropane with reduced catalyst was continued for 16 hours. The product isolated was 13.7 g (18.4 ml) of a hydrocarbon having n_D^{20} 1.4253; d_4^{20} 0.7513. Judging from these constants, the isopropenylcyclopropane remained unchanged.

Experiment 2. 2-Methyl-2-pentene, amounting to 19.8 g (28 ml), was taken, and 1030 ml of hydrogen was allowed to add, the theoretical amount for complete hydrogenation being 5270 ml. The catalyzate (17.5 g; 25.6 ml) had b.p. 60.0 – 65.5° (749.2 mm).

Experiment 3. 2-Methyl-1-pentene, amounting to 10.5 g (15.4 ml), was taken, and 660 ml of hydrogen was allowed to add, the theoretical amount for complete hydrogenation being 2790 ml. The catalyzate (8.2 g; 12.0 ml) had b.p. 60.0-65.0° (749.2 mm).

The catalyzates from Experiments 2 and 3 were analyzed with the aid of Raman spectra. The spectra of the isomerization products obtained in these experiments are quite identical; they are shown in Fig. 3.

SUMMARY

1. It was found that in the hydrogenation of isopropenylcyclopropane in alcohol solution in presence of palladium black at room temperature and atmospheric pressure two molecular proportions of hydrogen add with

Fig. 2. Raman spectra: 1) 2-methyl-1-pentene; 2) Sample II; 3) 2-methyl-2-pentene; 4) Sample III; 5) Sample IV; 6) isopropenylcyclopropane.

Fig. 3. Spectra of isomerization products: 1) 2-methyl-1-pentene; 2) 2-methyl-2-pentene.

formation of 2-methylpentane.

2. It was shown that the hydrogenation of isopropenylcyclopropane proceeds through the intermediate formation of 2-methyl-1-pentene and 2-methyl-2-pentene.

3. It was found that, under the hydrogenation conditions used, reversible isomerization of 2-methyl-2-pentene into 2-methyl-1-pentene occurs.

4. It was shown that isopropenylcyclopropane remains unchanged when shaken for a long time with reduced palladium black.

HIGH-TEMPERATURE REACTIONS OF PROPYL- AND ISOPROPYL-BENZENES OVER A NICKEL-ALUMINA CATALYST IN PRESENCE OF HYDROGEN AT HIGH PRESSURE

N. I. Shuikin, N. G. Berdnikova*, and Yu. P. Egorov

Various investigations have been devoted to the contact-catalysis reactions of aromatic hydrocarbons [1-3], and these have been mainly concerned with the study of reactions occurring at atmospheric pressure in presence of oxide catalysts. At the present time, however, there is much interest in the behavior of benzene homologs under the influence of oxide-metal catalysts in presence of hydrogen at high pressure [4].

We have already [5-7] published the results of investigations on the contact-catalysis reactions of some individual cycloalkanes, alkanes, and simple aromatic hydrocarbons at high temperature in presence of hydrogen at high pressure. On the basis of the experimental results then obtained we advanced a hypothesis concerning the character and direction of the reactions occurring over platinized alumina in presence of hydrogen at high pressure.

As early as 1934, one of us in collaboration with Zelinsky [8] showed that at 350° a nickel-alumina catalyst not only has a marked dehydrogenating action, but also has the ability to bring about a synthetic process: catalytic methylation of cyclic hydrocarbons by methylene radicals formed under the reaction conditions.

When planning the present investigation, we started from the assumption that the use of a high pressure of hydrogen in the catalysis of aromatic hydrocarbons would increase the stability of the catalyst and enable us to obtain a clearer picture of the synthetic processes of the type noted in earlier work.

EXPERIMENTAL

We investigated the behavior of the two isomers - propyl - and isopropyl-benzenes - in contact with finely dispersed nickel carried on activated alumina. In the catalysts used in the investigation the contents of active metal were 10, 20, and 30%. Their hydrogenating and dehydrogenating properties were first determined refractometrically for the transformations of benzene at 180° and of cyclohexane at 300°. It was found that in presence of the 20% or 30% nickel-alumina catalyst benzene was almost completely hydrogenated to cyclohexane under these conditions and cyclohexane was dehydrogenated to benzene to the extent of 98%.

After fractionation through a 42-plate column, the propylbenzene had the following properties: b.p. 159-159.7° (759 mm); n_D^{20} 1.4920; d_4^{20} 0.8621. The isopropylbenzene had b.p. 153.9-152.0° (758 mm); n_D^{20} 1.4915; d_4^{20} 0.8623.

These hydrocarbons were brought into contact with catalyst in a flow-type apparatus at a space velocity of 0.8 hr^{-1}, the molar ratio of hydrogen to hydrocarbon being about 5:1 [9]. The liquid catalysis products were investigated by means of precision rectification, chromatographic adsorption, and Raman spectra. The gaseous products were analyzed in an Orsat-Lunge apparatus. For each experiment 100 g of substance was taken.

Catalysis of Propylbenzene

Propylbenzene was brought into contact with nickel catalysts at 460-465° at hydrogen pressures of 25 and 50 atm. The catalysis results are given in Table 1.

As will be seen from Table 1, a change in the content of finely dispersed nickel in the catalyst from 30 to 10% results in a lowering of the extent of conversion of the propylbenzene by 10%. A detailed investigation was made on the catalyzate obtained by treating propylbenzene with nickel-alumina containing 20% Ni at 465° and 25 atm hydrogen pressure. For fractionation through the 42-plate column, 100 ml (86.6 g) of this catalyzate (n_D^{20} 1.4975; d_4^{20} 0.8661.) was taken. The fractionation results are given in Table 2.

* Deceased.

VII	133.7–136.5	7.9	1.4957	0.8673	9.2
VIII	136.5–149.0	2.8	1.4965	0.8669	3.2
IX	149.0–155.6	1.5	1.4915	0.8621	1.6
X	155.6–159.8	3.0	1.4918	0.8620	3.5
Residue		5.4	1.5015	—	6.2

It will be seen from the results given in Table 2 that Fraction I, judging from its properties, contains – apart from traces of benzene, which were detected by the formolite reaction – some alkanes and cycloalkanes. Removal of benzene from this fraction by chromatographic adsorption resulted in the separation of 4.8 ml of dearomatized fraction having n_D^{20} 1.4085 and d_4^{20} 0.7128. Optical analysis of this showed the presence of methylcyclopentane (about 60%), cyclohexane (about 15%), and hexane isomers (qualitatively). There was not enough of Fraction II for investigation.

The properties of Fraction III (78.9-80.1°) gave us reason to suppose that it contained benzene and some cyclohexane. In order to verify this supposition, part of the fraction was subjected to Zelinsky dehydrogenational catalysis. Platinized charcoal (4.5% Pt) was taken as catalyst, and the fraction was passed over this at 300-305° until there was no further change in refractive index (three successive passages). The catalyzate so obtained had n_D^{20} 1.5005 and d_4^{20} 0.8765. It follows that, in addition to benzene, Fraction III contained about 2% of cyclohexane [10]. Owing to the small amounts of material available, the intermediate fractions IV and VI were not investigated. Fraction V (109.5-110.9°) corresponded in its properties to almost pure toluene. Fraction VII (133.7-136.5°) was ethylbenzene. In the product obtained by permanganate oxidation of a small portion of this fraction [11] only benzoic acid, m.p. 120.8°, was found.

In order to determine the structures of the xylenes present in Fraction VIII (136.5-149.0°), it was subjected to Ullmann oxidation [11]. The resulting acids were separated by the method described by Moldavsky and coworkers [12]. From the mixture of acids (3.6 g), 0.4 g of benzoic acid (m.p. 120.8°), 1.3 g of isophthalic acid, 1.5 g of terephthalic acid, and 0.4 g of phthalic acid (m.p. 190°) were isolated. The isophthalic and terephthalic acids were converted into their methyl esters, which melted at 65° and 140°, respectively.

Fraction IX (149.0-155.6°) corresponded in properties to isopropylbenzene. The permanganate oxidation product of this fraction was found to be benzoic acid (m.p. 121°). Fraction X (155.6-159.8°) was mainly unchanged propylbenzene.

BLANK
PAGE

The residue (5.4 g) from the fractionation of the catalyzate was separated into the following fractions by distillation at 759 mm from a small flask attached to a fractionating column:

Fraction I	b.p. 159.8–169.8°;	3 g;	n_D^{20} 1.4920;	d_4^{20} 0.8619
Fraction II	b.p. 169.8–176.0°;	1.2 g;	n_D^{20} 1.4997;	d_4^{20} 0.8720
Fraction III	b.p. 176.0–184.0°;	0.7 g;	n_D^{20} 1.5447;	

Judging from its properties, Fraction I of this residue consisted essentially of unchanged propylbenzene. Oxidation of Fraction II yielded a mixture of phthalic acids (1.7 g) in which only isophthalic (0.8 g) and terephthalic (0.7 g) were identified, indicating the presence in the fraction of isomeric m- and p-dialkylbenzenes (probably ethyltoluenes).

On the basis of this investigation of the chemical composition of catalyzate fractions, we may present the following scheme of the transformations of propylbenzene under the conditions of our experiments:

Catalysis of Isopropylbenzene

The transformations of isopropylbenzene were investigated at 350°, 400°, and 465°, other conditions being the same. The results are given in Table 3.

It follows from the data given in Table 3 that rise of temperature from 350° to 465° results in a considerable increase in the yield of the products of complete and partial dealkylation of isopropylbenzene.

Reduction of the nickel content of the catalyst from 30% to 10% causes a comparatively small lowering of the degree of dealkylation of the isopropylbenzene. Increase of pressure from 25 to 50 atm at 465° has substantially no effect on the extent of conversion. A detailed investigation was made on the catalyzate obtained in the experiment carried out at 465° and 25 atm with a space velocity of 0.8 hr^{-1} over a nickel-alumina catalyst containing 20% Ni. The results of an analytical fractionation of 150 ml of the catalyzate through the 42-plate column are given in Table 4.

The properties of Fraction I (48–78.5°) gave us reason to suppose that, apart from benzene, it contained alkanes and cycloalkanes. After chromatographic removal of benzene, the dearomatized fraction (5.3 ml; n_D^{20} 1.4121 and d_4^{20} 0.7584) was analyzed optically. It was thus shown that this part of the fraction contained 65% of methylcyclopentane ($\Delta\nu$, cm^{-1}: 534, 845, 890, 1085, and others) and 30% of cyclohexane ($\Delta\nu$, cm^{-1}: 800, 1027, 1267, and others); hexane isomers were also detected qualitatively.

TABLE 3

XI	164.0–178.3	5.5	1.4945	0.8719	4.2
Residue		6.5	—	—	5.0

The properties of Fraction II (78.5-81.2°) gave us reason to suppose that it contained not only benzene, but also cyclohexane. In order to verify this supposition, part of the fraction was subjected to dehydrogenational catalysis in presence of platinized charcoal (4% Pt). After dehydrogenation the catalyzate consisted almost entirely of benzene. According to Zelinsky and Pavlov's curve [10], there must have been about 2.5% of cyclohexane in this fraction. Confirmation of the presence of cyclohexane in this fraction was obtained also from Raman spectra.

Aromatic hydrocarbons were removed from the intermediate Fraction III (81.2-109.0°), and it was then analyzed by the Raman spectrum method. Methylcyclohexane (about 70%) and heptane isomers (qualitatively) were detected in the dearomatized fraction.

Fraction IV (109-111.0°) corresponded in properties to almost pure toluene.

The intermediate Fraction V (111.0-133.5°) was not investigated owing to the smallness of the amount, but Fraction VI, judging from its properties, consisted essentially of ethylbenzene together with some m- and p-xylenes. Fraction VII (137-148.0°) was subjected to optical analysis. The results showed that in this xylene fraction there was about 10% of ethylbenzene ($\Delta\nu$ cm^{-1} : 159, 622, 771, 969, 1005, 1050, and others), 60% of m-xylene (230, 295, 540, 725, 1000, 1250, 1379, 1613), 15% of p-xylene (313, 460, 645, 829, 1183, 1205, 1379, 3054, and others), and 10% of o-xylene (179, 580, 735, 1054, 1223, 1384, 1609); in addition, it was established qualitatively

that a C_5 cyclopentane derivative was present in this fraction. Fraction VII (148-156°) was close to the original isopropylbenzene in properties. Fraction IX contained mainly propylbenzene, probably formed by the isomerization of isopropylbenzene; only benzoic acid (m.p. 120.8°) was found in its permanganate oxidation product. Fractions X and XI were subjected to optical analysis. Fraction X contained about 40% of propylbenzene, about 40% of p-ethyltoluene, and 20% of m-ethyltoluene; also, the presence of a small amount of trimethylbenzenes was established qualitatively.

It was shown that Fraction XI consisted largely of p-isopropyltoluene, but meta derivatives of propylbenzene were also present.

The investigation of the isopropylbenzene catalyzate showed that the main reaction under the given conditions was partial and complete dealkylation of isopropylbenzene with formation of benzene (32%), toluene (20.2%), and ethylbenzene (12.8%). Simultaneously with this main reaction, other transformations also occurred: hydrogenation of the benzene nucleus to the cyclohexane ring, contraction of this ring to a five-membered ring, hydrogenolysis of the five-membered ring with formation of alkanes, and partial isomerization of isopropylbenzene into propylbenzene.

The presence in the catalyzate of xylenes and trimethylbenzenes may be explained by methylation of the benzene nucleus by methylene radicals, which, as we have suggested previously, are probably formed by the decomposition (at the surface of the nickel-alumina catalyst of cycloalkanes that are formed in the process. This explanation, however, is not the only possible one, for we cannot exclude the possibility that isopropylbenzene may isomerize to trimethylbenzene under our conditions and that hydrogenolysis of a methyl group may then occur:

Thus, the composition of the mixture of hydrocarbons formed as a result of the catalytic treatment of isopropylbenzene indicates the great variety of the reactions occurring under conditions of high temperature and high pressure of hydrogen. These reactions probably proceed in accordance with the following scheme:

SUMMARY

1. The contact-catalysis transformations of propyl- and isopropyl-benzenes were investigated at a nickel-alumina catalyst at various temperatures (350-465°) and at hydrogen pressures of 25 and 50 atm.

2. It was found that, under these catalysis conditions at 465°, about 98% of the original hydrocarbon undergoes far-reaching transformations.

3. It was shown that the main reaction in the transformations of propyl- and isopropyl-benzenes is the

hydrogenolysis of the side chain with formation of complete and partial dealkylation products: benzene, toluene, and ethylbenzene. Proceeding simultaneously with hydrogenolysis are reactions of hydrogenation of the benzene ring, contraction of a six-membered ring to a five-membered, hydrogenolysis of the latter, and isomerization of the side chain of the original hydrocarbon (propyl into isopropyl, and vice versa).

4. The transformations of the investigated hydrocarbons included their methylation by methylene radicals formed by the decomposition of cycloalkanes (produced in the process) at the surface of the nickel-alumina catalyst.

REACTIVITY AND MOLECULAR OPTICAL PROPERTIES OF ALKENYLSILANES

A. D. Petrov, Yu. P. Egorov, V. F. Mironov, G. I. Nikishin, and A. A. Bugorkova

There is much information in the literature on the evaluation of the effect of σ, π-conjugation on reactivity in various organic compounds [1]. In the case of organosilicon compounds the conjugation of double bonds with an Si—C bond has not yet been noted, and the reactivities of conjugated and nonconjugated double bonds in alkenylsilanes of various structure have not been subjected to a comparative quantitative study.

Over a period of years we have synthesized various unsaturated "silahydrocarbons" having a double bond in the α-, β-, γ-, or δ-position with respect to the silicon atom, and on several occasions we have pointed out qualitative differences between these alkenylsilanes in addition reactions [2-11]. We noted the exceptionally high activity of 2-alkenylsilanes (allylsilanes) in reactions with HBr, BR_2, $HS_2P(OR)_2$, and other substances [3-10]. For example, $(C_2H_5)_3SiCH_2CH=CH_2$ combined almost instantaneously with HBr at -70° [2], whereas $(C_2H_5)_3SiCH=CH_2$ [3], $(CH_3)_3SiCH_2CH=CH_2$ [4] and $(C_2H_5)_3SiCH_2CH_2CH=CH_2$ [5] reacted extremely slowly with HBr even at room temperature. Moreover, it was established that HBr adds to $(C_2H_5)_3SiCH=CH_2$ in the direction contrary to that by Markovnikov's rule [3], that it adds to $(C_2H_5)_3SiCH_2CH=CH_2$ entirely in the direction required by the rule [5] even in presence of peroxide [6], and that $(CH_3)_3SiCH_2CH_2CH=CH_2$, though undergoing addition of HBr in accordance with the rule, like the olefine [4], is also able to react contrary to the rule with HBr in presence of peroxides [12].

In the present investigation—with the object of evaluating quantitatively the effect of molecular structure on double-bond reactivity in alkenylsilanes, and with the object also of examining the phenomenon of alternation—we selected the thiocyanation reaction [13] (readily controllable with respect to time) and the intensities of the characteristic double-bond frequencies in the Raman and infrared spectra as objects for study. As can be seen from the results cited below, the alternation of the intensities of the Raman spectrum lines (double-bond frequencies 1630-1649 cm^{-1}) can be observed as far as the δ-position of the double-bond (Fig. 1). The intensity of these frequencies is least for the α-position, greatest for the β-position, and intermediate in value for the γ-position. An analogous curve is obtained for the variation of the intensity of the C = C band ($\sim$6.2 μ) in the infrared adsorption spectra (Fig. 2).

On the basis of refractometric measurements Fajans [14] concluded that the alternation of charges proceeds beyond the β-position. Whereas the alternation in the effect of the silicon atom on the direction of HBr addition ends at the β-double bond, the alternation in the rate of thiocyanogen addition extends to the γ-position (Fig. 3); beyond this there is a uniform diminution of the effect of the silicon atom along the carbon chain. It can be seen from the same graph that, in compounds of the type $R_3Si(CH_2)nCH=CH_2$ where $n = 0-4$, the double-bond is ten times (for the 5-minute and 1-hour curves) as active when $n = 1$ (2-alkenylsilanes) than when $n = 0$ (1-alkenylsilanes); 1-alkenylsilanes have about one-quarter of the activity of 3-alkenylsilanes ($n = 2$) and are approximately equal in activity to 4- and 5-alkenylsilanes.

The parallelism between the physical and chemical properties of alkenylsilanes of the type $R_3Si(CH_2)nCH=CH_2$ extends also to alkenylsilanes of other types. It was found that the presence of a methyl group at the double bond, irrespective of its position with respect to the Si atom, greatly raises the chemical activity of the double bond and the intensities of its characteristic frequencies in the Raman spectrum. For example, the intensities of the C = C frequencies of $(CH_3)_3SiC(CH_3)=CH_2$ and $(CH_3)_3SiCH=C(CH_3)_2$ were found to be 50 % greater than those of $(C_2H_5)_3SiCH=CH_2$. Still more marked was the continuous increase in the rate of thiocyanogen addition in a series of vinylsilanes, ranging from the unsubstituted vinyl compound, through the 2- and 1-methylvinyl compounds, to the 1,2-dimethylvinyl compound (Fig. 4).

For the 3-alkenylsilanes $(CH_3)_3SiCH_2CH_2CH=CH_2$ and $(CH_3)_3SiCH_2CH_2C(CH_3)=CH_2$ the rates of thiocyanation

differ greatly, the rate for the second compound being ten times as high as that for the first.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Comparison of calculated and determined molecular refractions for compounds of the type $R_3Si(CH_2)nCH=CH_2$ shows definite exaltation for allylsilanes ($n=1$), but absence of any exaltation in compounds for which $n=0,2,3$, and 4. For polyallylsilanes the exaltation rises in proportion to the number of allyl groups [15]. Alkenylsilanes having a branch at the double bond (for example, $(CH_3)_3SiCH=C(CH_3)-CH_3$, $(CH_3)_2SiCH_2CH_2C(CH_3)=CH_2$), irrespective of the position of the double bond with respect to the silicon atom, also show exaltation of molecular refraction [7, 11]. It is interesting to note that exaltation was found also when saturated ethyl and butyl radicals were attached to the silicon atom, but not in the case of methyl and propyl radicals (Table 1).

These phenomena were revealed when we calculated MR from the generally accepted values of the bond refractions [16] (Table 1). The use of group refractions for radicals attached to silicon as calculated by us from the constants of a large number of compounds has greater accuracy and convenience for the calculation of MR.

The peculiar physical properties of the allylsilanes, such as the high intensity of the double-bond Raman lines and infrared bands and the exaltation of molecular refraction, and also their high chemical activity, clearly indicate the presence in these compounds of conjugation between the double bond and the Si—C bond (σ, π-conjugation). Alkenylsilanes having methyl groups at the double bond also have these same physical and chemical peculiarities, and in this case the explanation lies in the conjugation of the double bond with C—H bonds of the CH_3 group, the hydrogens of which are strongly protonized.

An interesting peculiarity of the silicon atom is its "barrier" character with respect to the transmission of interaction between the radicals that are attached to it. This peculiarity is manifested in the proportionate growth of the intensity of the lines characterizing the $CH_2CH=CH_2$ group [15], in the constancy of the intensity of the C=C frequencies when the radicals attached to silicon are varied [17], in the stability of the characteristic frequencies in various saturated radicals [17,18], in the proportionate growth of the exaltation of molecular refraction with increase in the number of alkenyl groups, and in the nondependence of the rate of thiocyanogen addition on the number of alkenyl groups (Table 2) [13]. It may be supposed that this property is to be explained

both by the large mass of the silicon atom (as compared with carbon) and also by its greater atomic volume.

TABLE 1

Group Refractions of some Radicals attached to Silicon (ml/mole)

No.	Group attached to silicon	Our determined value of the refraction of Si—C bond	Group refraction	
			Found by us	Calculated [16]
1	Si—CH=CH$_2$	2.5	11.73	11.73
2	Si—CH$_2$CH=CH$_2$	2.68	16.54	16.36
3	Si—CH=CH—CH$_3$	2.85	16.71	16.36
4	Si—C(CH$_3$)=CH$_2$	2.5	16.36	16.36
5	Si—CH$_2$CH$_2$CH=CH$_2$	2.5	20.99	20.99
6	Si—CH$_2$C(CH$_3$)=CH$_2$	2.55	21.04	20.99
7	Si—CH=C(CH$_3$)—CH$_3$	2.95	21.44	20.99
8	SiCH$_2$CH$_2$C(CH$_3$)=CH$_2$	2.7	25.82	25.62
9	Si—C≡C—CH=CH$_2$		20.68	19.38
10	Si—CH$_3$	2.5	7.57	7.57
11	Si—C$_2$H$_5$	2.38	12.08	12.20
12	Si—n-C$_3$H$_7$	2.5	16.83	16.83
13	Si—n-C$_4$H$_9$	2.42	21.38	21.46
14	Si—CH$_2$Cl	2.5	12.41	12.41
15	Si—CH$_2$OH	2.5	9.12	9.12
16	Si—CH$_2$SCN	—	19.93	—
17	Si—Br	2.6	10.30	10.20
18	Si—OH	2.52	3.5	3.48

The rate of the thiocyanation reaction was determined by the method described earlier [13].

The Raman spectra were measured in the usual way [19]; the intensity was evaluated on the scale adopted in the USSR, on which the intensity of the 802 cm^{-1} line of cyclohexane is taken to be 250 units. In the comparison of the intensities of the Raman frequencies of C = C bonds in various alkenylsilanes, the integral value of the intensity was used; it was determined photometrically [19].

The infrared adsorption spectra were determined with an IKS-11 spectrometer by the usual method. In estimating the intensity of a band, we considered its value at the maximum and corrected it for the width of the slit [20]. Below we give the Raman spectra of the compounds discussed in this paper or prepared for the first time.

3-Butenyltriethylsilane $CH_2 = CHCH_2CH_2Si(C_2H_5)_3$ (I)

$\Delta\nu$: 168 (10) 267 (8b), 302 (10), 435 (6), 556 (60b), 617 (1), 636 (b) . 735 (3), 765 (7), 913 (12), 973(15), 1005 (20b),1020(20b), 1112 (10b), 1134(5), 1172 (2), 1197 (2), 1236 (20), 1279 (15), 1296 (20),1376(2),1414(40), 1468 (30), 1640 (50), 2879 (150b), 2902 (100b), 2938 (10), 2954 (55), 3000 (40), 3083 (20).

3-Butenylethyldimethylsilane $CH_2 = CHCH_2CH_2Si(CH_3)_2C_2H_5$ (II)

$\Delta\nu$: 153(15), 174 (15), 208 (10), 466 (6), 517 (10), 579 (60), 602 (5), 685 (15), 710 (10), 833 (5), 900 (10b), 913 (10b), 972 (2), 990 (2), 1015 (15), 1114 (5), 1164 (8), 1181 (8), 1234 (1), 1249 (8), 1280 (20), 1298 (20), 1359 (5),1416 (35), 1455 (10), 1640 (50), 2846 (8), 2878 (1000b), 2900 (100b) . 2940 (2), 2955 (60), 2972 (5), 3000 (45), 3080 (20).

3-Butenyltrimethylsilane $CH_2 = CHCH_2CH_2Si(CH_3)_3$ (III)

$\Delta\nu$: 148 (20), 207 (35 background), 247 (10 background), 274 (5), 324 (10), 438 (10) 518 (5b), 577 (10), 588 (30sh), 613(15sh), 685 (10), 802 (20), 850 (5), 889 (5), 899 (15b), 913 (15b), 990 (5), 1015 (12), 1115 (5) 1176 (5), 1252 (10), 1280 (20), 1298 (25), 1415 (10), 1445 (5), 1640 (60), 2845 (20), 2885 (100b), 2899 (150b), 2959 (80), 2972 (5), 3000 (20), 3080 (20).

TABLE 2

Rate of Addition of Thiocyanogen to Alkenylsilanes

Formula of Alkenylsilane	Amount of thiocyanogen added (%)		
	5minutes	1 hour	1 day
$(C_2H_5)_3SiCH=CH_2$	4.8	19.4	89.3
$(CH_3)_2SiCH=CHCH_3$	42.1	99	99.5
$(CH_3)_2SiC(CH_3)=CH_2$	64.3	80.7	98.9
$(CH_3)_2SiC(C_2H_5)=CH_2$	41.2	52.5	91.4
$(C_2H_5)_2SiCH=CCH_3$ $\quad\quad\quad

1176 (5), 1252 (10), 1280 (20) 1298 (25), 1415 (30), 1445 (5), 1640 (60), 2845 (10), 2880 (100b), 2899 (150b), 2959 (80), 2972 (5), 3000 (40), 3080 (20).

Trimethyl(2-methylpropenyl)silane $(CH_3)_3SiCH=C(CH_3)_2$ (IV)

$\Delta\nu$: 167 (20 background), 210 (20 background), 227 (30b), 252 (5), 363 (10), 452 (25), 615 (120), 662 (6), 690 (30b), 836 (8), 1061 (10), 1120 (5), 1148 (5), 1250 (10), 1310 (15), 1370 (25), 1414 (8), 1445 (40), 1623 (55) 2851 (30), 2905 (75b), 2930 (10sh), 2956 (85b).

Dimethyldi(2-methylpropenyl)silane $(CH_3)_2Si[CH=C(CH_3)_2]_2$ (V).

$\Delta\nu$: 169 (5 background), 224 (15b), 284 (15b), 306, 352 (15), 448 (6), 465 (12), 629 (2), 650 (20) 683 (15), 695 (5b), 830 (5), 849 (5), 1064 (15), 1120 (2), 1149 (4), 1251 (6), 1310 (20), 1372 (35), 1414 (3), 1444 (55), 1623 (70), 2856 (35), 2899 (20), 2908 (75b), 2927 (20), 2959 (25 doublet).

Trimethylpropenylsilane $CH_3CH=CHSi(CH_3)_3$ (VI)

$\Delta\nu$: 144 (10), 208 (40), 228 (30), 307 (25b), 336 (25), 390 (50), 508 (3), 615 (115), 684 (30), 705 (25b), 768 (7), 835 (12b), 1038 (5), 1110 (5), 1258 (15), 1315 (50), 1374 (15), 1415 (10), 1446 (25), 1621 (60), 2853 (20), 2898 (100), 2921 (50), 2967 (85b).

Isopropenyltrimethylsilane $CH_2=C(CH_3)Si(CH_3)_3$ (VII)

$\Delta\nu$: 148 (20b), 214 (30b), 242 (25), 290 (15), 370 (10), 570 (85), 652 (25), 690 (25), 757 (2), 835 (8), 938 (15), (1222), 1258 (10), 1372 (8), 1415 (50), 1444 (5), 1605 (55), 2856 (5), 2900 (80), 2965 (95), 3050 (15).

Trimethyl(2-methylallyl)silane $CH_2=\underset{\displaystyle CH_3}{\overset{|}{C}}CH_2Si(CH_3)_3$ (VIII)

$\Delta\nu$: 165 (40b), 235 (30), 267 (10), 391 (5), 423 (15), 490 (30sh), 597 (150), 658 (15), 690 (20), 716 (5), 769 (2), 828 (18), 871 (15), 974 (2), 998 (5), 1126 (25), 1160 (25), 1260 (5b), 1282 (7), 1315 (2), 1396 (15), 1410 (25), 1440 (5), 1638 (70), 2900 (100), 2912 (30) 2968 (80b), 2983 (20), 3080 (20).

2,2,5,5-Tetramethyl-2,5-disila-3-hexene $(CH_3)_3SiCH=CHSi(CH_3)_3$ (IX).

$\Delta\nu$: 183 (35b), 228 (15b), 325 (25), 610 (300), 683 (10), 698 (50), 789 (5), 842 (10), 882 (2), 1248 (15), 1258 (15), 1295 (40sh), 1387 (2), 1412 (20b), 1551-1571 (20 very b), 2900 (150), 2928 (25), 2961 (150).

In the spectra of compounds (I-III), which contain the group $CH_2=CHCH_2CH_2$– at Si, there is a group of stable frequencies 913, 1112, 1280, 1298, 1640, 3000, 3080 cm^{-1} which probably belong to vibrations in the terminal $CH=CH_2$ group. In the 2-methylpropenylsilanes (IV) and (V) the characteristic lines 1064, 1310, 1370, and 1623 cm^{-1} are present. The intensity of these lines increases with increase in the number of 2-methylpropenyl groups. We must point out the increase in the double bond frequency from 1594 cm^{-1} in vinylsilanes to 1623 cm^{-1} in 2-methylpropenylsilanes. A very similar value for the C=C frequency is found also in the compound (VI) (1621 cm^{-1}). Thus, the displacement of the double bond from the end to the second place in the chain causes an increase in its characteristic frequency by 30 cm^{-1}. – behavior that is generally observed also in alkenes. In compounds (VII) and (VIII) a CH_2 group is attached to the first carbon atom (reckoned from the direction of Si) of the C=C bond and this immediately causes a rise in the C=C frequency from 1594 and 1630 cm^{-1} to 1605 and 1638 cm^{-1}, respectively. The α-position of the $=CH_2$ group is also very well characterized by the position of the antisymmetrical frequency of C–H in this group (3050 cm^{-1}); in β-, γ-, and δ-positions it is always higher, being 3080 cm^{-1}. In the compound (IX) there is a broadening of the double-bond frequencies by 20 cm^{-1}, which may be explained by cis-trans isomerism and by the breadth of these lines.

SUMMARY

1. It was established that there is a parallelism between the rates of thiocyanogen addition and the intensity of Raman lines for a large number of alkenylsilanes of various structures.

2. It was shown that allylsilanes and alkenylsilanes having a tertiary double bond are characterized by particularly high double-bond activity in addition reactions, by high-intensity Raman lines and infrared absorption bands, and by exaltation of molecular refraction. It was suggested that these peculiarities of the above classes of alkenylsilanes are to be attributed to σ,π-conjugation.

3. It was shown that the alternation in the intensities of the double-bond lines of the Raman spectrum and absorption bands of the infrared spectra extends to the δ- and ϵ-double-bond positions, and the alternation in the rates of thiocyanogen addition extends to the γ-double-bond position.

HOMOGENEOUS DESTRUCTIVE HYDROGENATION OF ISOPROPYLBENZENE UNDER HIGH PRESSURES OF HYDROGEN

M. G. Gonikberg and V. E. Nikitenkov

The thermal decomposition of isopropylbenzene has been investigated by several authors. In a paper by Dobryansky, Kanep, and Katsman [1] data are given on the pyrolysis of isopropylbenzene at 650°. They obtained 88.7 % of liquid products and 9.1 % of gas. Among the liquid products they found benzene (6%), toluene (0.5%), and styrene (44%). Among the gaseous products they found H_2 (28.8%) and hydrocarbons: C_2 3.4%, C_3 6.8% C_nH_{n-2} 60.0% the amounts of methane and hydrogen being approximately equal. In another investigation a study was made of the thermal decomposition of isopropylbenzene occurring in the course of ten minutes at 586° under a pressure of 400 mm [2]. Analysis of the gaseous products of the reaction showed that it contained about 27% of hydrogen, about 60% of methane, and about 13% of ethane. In 1952 there appeared a study of the thermal cracking of isopropylbenzene in a flow apparatus at 700°, the time in the heating zone being 0.011second [3]. The total extent of the transformation of isopropylbenzene was (as a mole percentage) 2.1, the products including α-methylstyrene 1.3, styrene 0.4, xylenes 0.1, toluene 0.1, and benzene 0.21. Among the gaseous products were found (mole-%): hydrogen 1.6, methane 0.8, ethylene 0.1, and propene 0.1. Leigh and Szwarc [4] studied the pyrolysis of isopropylbenzene at 639-728° in a flow system in presence of a large excess of toluene, the time of contact being 0.41-0.46 second. They established that the primary act of the thermal decomposition of isopropylbenzene is the reaction:

$$C_6H_5CH(CH_3)_2 \longrightarrow C_6H_5\dot{C}HCH_3 + \dot{C}H_3$$

A paper appearing in 1953 [5] describes an investigation of the thermal transformation of isopropylbenzene in a flow system at 479°, 501°, and 528° (at space velocities if 1.00, 1.35, and 1.46 hr^{-1}, respectively) under a pressure of 816 atm. The total extents of conversion of the isopropylbenzene under these conditions were 22.6, 45.8, and 76.0%, respectively. Among the liquid reaction products a considerable amount of propylbenzene was found, the yield falling with rise in temperature (55.9 mole-% on the isopropylbenzene that reacted at 479°; 17.8 mole-% at 528°). At 479° no benzene could be detected among the reaction products and the yields of toluene and ethylbenzene (mole-% on the amount of isopropylbenzene that reacted) were 5.1 and 15.4, respectively; at 528° the yields were 5.1 of benzene, 26.5 of toluene, and 22.8 of ethylbenzene. At 479° the gaseous reaction products included (mole-%) 10.4 of hydrogen, 70.0 of methane, 9.2 of ethane, 5.4 of propene, 5.4 of propane, and 1.3 of the butane isomers. At the higher temperature of 528°, the contents (mole-%) of the gases were 0.6 of hydrogen, 77.8 of methane, 15.0 of ethane, 0.5 of propene, 5.0 of propane, and 1.0 of the butane isomers. These data show that, in the thermal decomposition of isopropylbenzene, a mixture containing a large number of hydrocarbons is formed; in addition to the thermal decomposition of isopropylbenzene there occurs the dehydrogenation of this substance and its decomposition products (into styrene and α-methylstyrene), and also the formation of propylbenzene.

Carrying out the thermal cracking of alkylbenzenes in presence of hydrogen (homogeneous destructive hydrogenation) has a substantial effect on the rate and direction of the decomposition processes, leading to the formation of mainly benzene. Some data on the homogeneous destructive hydrogenation of alkylbenzenes (toluene, ethylbenzene, propylbenzene, and butylbenzene) are given in the review article by Nemtsov [6]. The author considers that this process is a bimolecular reaction between the alkylbenzene and hydrogen. In this work it is shown that a metal packing has no effect on the reaction rate. In the reaction of ethylbenzene it was found that the yield of benzene increased and that of toluene diminished as the hydrogen pressure was increased. In a previous investigation [7] we studied the homogeneous destructive hydrogenation of toluene at 455-490° under hydrogen pressures of up to 1350 atm. On the basis of the results obtained we developed a scheme for the process based on a chain mechanism. In the present paper we give the results of an investigation on the homogeneous destructive hydrogenation of isopropylbenzene under high pressures of hydrogen.

EXPERIMENTAL

The investigation was carried out in a shaken stainless steel autoclave having a hydraulic seal (volume with manometer about 105 ml). Isopropylbenzene was introduced into the reactor, which was then closed. The pressure in the reactor was raised by means of a multiplying device fed from a cylinder. The isopropylbenzene was first distilled through a 30-plate column; it had the following constants: b.p. 152.2-152.4° (760 mm); n_D^{20} 1.4915. The literature [3] gives b.p. 152.39° (760 mm); n_D^{20} 1.4915. The charge of isopropylbenzene was the same in all experiments (30 g). In the various experiments the initial pressure of hydrogen ranged from 50 to 300 atm. The reactor was then heated to the required temperature.

Fig. 1. Fractionation curve for liquid products of Experiment 19 (475°, P_{H_2} initially 50 atm, 5 hours)

The temperature was measured by means of a thermocouple contained in a long pocket inside the reactor which passed through the hydraulic seal. The temperature was maintained constant within ±2°. For this experiment the reactor was maintained at the required temperature for the required time and then cooled. In various experiments the working pressure ranged from 170 to 680 atm. At the end of the experiment the pressure was slowly lowered to that of the atmosphere. The liquid products were fractionated through a 30-plate column, fractions containing benzene, toluene, ethylbenzene, and isopropylbenzene being separated. A typical fractionation curve for liquid products obtained at an initial hydrogen pressure of 50 atm is given in Fig. 1. On this curve four horizontal portions – corresponding to benzene, toluene, ethylbenzene, and isopropylbenzene – can be clearly seen. In the fractions isolated, unsaturated hydrocarbons were estimated bromometrically; only very small amounts were found. Thus, for a working pressure of 190-210 atm, the bromine values of fractions boiling below 137° were only 0.1-0.5, and those of fractions boiling at 137-159°, 1.2-3.1. For the highest working pressures (680 atm) the corresponding fractions contained no unsaturated hydrocarbons at all. Hence, in calculating the benzene, toluene, ethylbenzene, and isopropylbenzene contents, we took no account of the presence of unsaturated hydrocarbons. In the fractionation we separated the following fractions:

Fraction I	b.p. up to 81°		Fraction V	b.p.	135–137°
Fraction II	b.p.	81–110°	Fraction VI	b.p	137–151°
Fraction III	b.p.	110–111°	Fraction VII	b.p.	151–153°
Fraction IV	b.p.	111–135°	Fraction VIII (in some cases up to 159°).	b.p.	153–156°

The residues were investigated separately.

The gaseous products were first investigated for their contents of hydrogen and unsaturated hydrocarbons by Hempel's method. They were then fractionated through a Podbielniak column, and the methane, ethane, and propane fractions were again investigated by Hempel's method. Fractionation curves for the gaseous hydrocarbon products from experiments at initial hydrogen pressures of 50 and 300 atm are given in Figures 2 and 3.

The contents of gaseous saturated hydrocarbons in the reaction products were calculated from the fractionation curves. Toward the end of the fractionation the temperature in the column began to rise (to −10°–0°) as a result of the exhaustion of the gas being fractionated. There were no plateaux on the curve corresponding to butane or isobutane, and we therefore took the fraction boiling above −65.3° to be propane. There were small amounts of ethylene in the ethane fraction, but no unsaturated hydrocarbons could be detected in the propane fraction.

RESULTS OF THE INVESTIGATION

a) Effect of the Hydrogen Pressure on the Content of Unsaturated Hydrocarbons in the Reaction Products. The effect of pressure on the content of unsaturated hydrocarbons in fractions boiling up to 156–159° is discussed above. The bromine values of the high-boiling products (residues) are given in Table 1.

Fig. 2. Fractionation curve for gaseous products of Experiment 42 (475°, P_{H_2} initially 50 atm, 3 hours)

Fig. 3. Fractionation curve for gaseous products of Experiment 41 (475°, P_{H_2} initially 300 atm, 3 hours).

As will be seen from Table 1, the bromine numbers of the high-boiling products, which are 19.0-19.3 for a working pressure of 170-190 atm, are reduced to zero when the working pressure is 680-650 atm.

b) Effect of the Duration of the Experiment on the Rate and Direction of the Process. Data are given in Tables 2-4 on the effect of the duration of experiments at 475° on the composition of the liquid reaction products for a series of experiments carried out at a given working pressure.

It follows from Tables 2-4 that with increase in the duration of the experiment the yield of benzene increases at all pressures studied.

At a working pressure of 280-300 atm increase in the duration of the experiment from 3 to 6 hours results also in an increase in the yield of toluene. At a working pressure of 460-490 atm the yields of benzene are higher and those of toluene and ethylbenzene are lower than at a working pressure of 280-300 atm. Here again the yield of benzene increases with increase in the duration of the experiment, but the yields of toluene and ethylbenzene change very little. At a working pressure of 640-680 atm the yields of toluene and ethylbenzene are extremely small. The data in Tables 2-4 show also that the results of parallel experiments are in agreement; the average discrepancies in the yields of hydrocarbons are about 2% (on the charge).

c) Effect of Hydrogen Pressure on the Composition of the Liquid Reaction Products. In Tables 5-7 we give data relating to the effect of the pressure of hydrogen on the composition of the liquid reaction products for experiments differing in duration (3, 4, and 5 hours) at 475°.

TABLE 1

Quantity of Bromine Residue (b.p.>156°)

Expt. No.	Working pressure (atm)	Duration of Experiment (hours)	Bromine values
25	170-190	3	19.32; 19.04
19	190-210	5	12.51; 12.51
14	390	5	2.52; 2.51
13	490	2	1.63
7	490-480	5	1.38
4	660-650	5	0; 0

It follows from Tables 5-7 that, for a given time of reaction, with increase in hydrogen pressure the yields of toluene and ethylbenzene diminish and the yield of benzene and the amount of unchanged isopropylbenzene increase. For example, in three-hour experiments, with increase in pressure from 170-190 to 650-680 atm the yield of toluene and ethylbenzene is reduced by a factor of six, while that of benzene is increased by the same factor. The effect of pressure is seen equally clearly in the five-hour experiments. Increase in pressure from 190-210 to 640-660 atm resulted in falls in the yields of toluene and ethylbenzene from 15.6 and 19.5%, respectively.

to zero, whereas the yield of benzene increased six-fold.

The fractionation curve for Experiment 4 is shown in Fig. 4. Comparison of this curve with the fractionation curve for the liquid product obtained at the same temperature and in the same time at a working pressure of 190–210 atm (Experiment 19, Fig. 1) clearly illustrates the effect of pressure on the direction of the process of homogeneous destructive hydrogenation of isopropylbenzene.

Fig. 4. Fractionation curve for liquid products of Experiment 4 (475°, P_{H_2} initially 300 atm, 5 hours)

As will be seen from the tables, the maximum yield of benzene was 55.9 % by weight on the amount of isopropylbenzene taken; the theoretical maximum yield is 65% by weight. We also carried out three- and five-hour experiments at 475° in absence of hydrogen. No benzene at all was obtained in these experiments; the yields of toluene and ethylbenzene were somewhat lower (respectively 6.0 and 12.8% in three hours, and 10.5 and 16.9% in five hours) than when hydrogen was present initially at 50 atm (Experiments 25 and 19). It must be concluded that the introduction of hydrogen into the sphere of reaction not only greatly accelerates the formation of benzene, but also accelerates the formation of ethylbenzene and toluene, although to a much lower extent.

Table 8 gives data on the effect of hydrogen pressure on the composition of the liquid products of reaction at 452° for five hours.

TABLE 8

Homogeneous Destructive Hydrogenation of Isopropylbenzene at 452° (in Five Hours)

Expt. No.	Working pressure (atm)	Yield of liquid products (% by weight on charge) •					
		Including / Total	Benzene	Toluene	Ethylbenzene	Isopropylbenzene	Fraction boiling above 156°
2	300–280	91.8	18.9	4.3	8.3	52.4	6.7
3	620–560	73.6	33.9	2.4	4.7	19.6	8.7

• Taking into account a loss of 2 g when unloading reactor.

It will be seen from Table 8 that at 452° increase of pressure from 300-280 to 620-560 atm resulted in a reduction (1.7 - and 1.8- fold, respectively) in the yields of toluene and ethylbenzene and a simultaneous increase (1.8 fold) in the yield of benzene; there was a 1.7-fold increase in the amount of unchanged isopropylbenzene.

d) Effect of Hydrogen Pressure on the Composition of the Gaseous Reaction Products. The results of the investigation of the gaseous reaction products are given in Table 9. The fractionation curves for the gaseous products of Experiments 41 and 42 are shown in Figures 2 and 3.

It will be seen from Table 9 and the fractionation curves that with increase in hydrogen pressure there is a considerable increase in the propane content of the gas with simultaneous reduction in the methane content. The variation with pressure of the ratio of the propane content to the sum of the methane and ethane contents is shown in Fig. 5, which indicates that this ratio is approximately proportional to the initial pressure of hydrogen.

e) Effect of Temperature on the Composition of the Liquid Reaction Products. Table 10 gives data on the effect of temperature on the yields of liquid reaction products for initial hydrogen pressures of 100 and 300 atm. It follows from Table 10 that at working pressures of 280-300 atm (initial hydrogen pressure 100 atm) a lowering of the temperature from 475° to 452° results in a 2.5-fold reduction in the yield of toluene and a two -fold reduction in the yield of ethylbenzene. The yield of benzene is very slightly reduced (by 4-5 %). The proportion of unchanged isopropylbenzene is reduced from 83.0 to 47.6%, which indicates a high temperature coefficient for the reaction.

TABLE 9

Analysis of Gaseous Reaction Products (3-hour experiment)

Fig. 5. Effect of the Initial Hydrogen Pressure on the Ratio, $(C_3H_6):[CH_4+(C_2H_6)]$ at 475° (3 hours).

f) Investigation of the High-boiling Reaction Products. As it could be expected that under the conditions of our experiments propylbenzene would be formed [5], we attempted to isolate propylbenzene from the high-boiling reaction products (residues, b.p. above 156°). Fractionation of these residues yielded propylbenzene, b.p. 158.7-159.2° (760 mm); n_D^{20} 1.4920 (the literature gives b.p. 159.22°; n_D^{18} 1.4920). Propylbenzene was acetylated by the method described in the paper [9]; the semicarbazone obtained from the propylacetophenone melted at 181.0-181.5° (the literature [5] gives 181.0-181.5°). Analysis of the semicarbazone gave:

Found%: N 19.32

$C_{12}H_{17}N_3O$. Calculated%: N 19.13

From the high-boiling residues obtained in experiments at an initial hydrogen pressure of 300 atm, biphenyl was isolated. It melted at 69.5-70° (the literature gives 70.0°), and there was no melting point depression in admixture with pure biphenyl.

Found%: C 93.29; 93.44; H 6.45; 6.59

$C_{12}H_{10}$. Calculated%: C 93.46; H 6.54

From the high-boiling residues obtained in experiments at an initial hydrogen pressure of 50 atm, naphthalene, m.p. 79.5-80°, was isolated.

Found%: C 93.37; 93.74; H 6.29; 6.31

$C_{10}H_8$. Calculated%: C 93.71; H 6.29

Fractionation of these residues yielded also a fraction having b.p. 277-280° (760 mm); n_D^{20} 1.5928. This fraction was evidently bitolyl [7].

Found%: C 92.35; 92.41 H 7.59; 7.56

$C_{14}H_{14}$. Calculated%: C 92.26; H 7.74

DISCUSSION OF RESULTS

The principal results of the investigation can be stated as follows: a) as would be expected, increase of the pressure of hydrogen in the homogeneous destructive hydrogenation of isopropylbenzene causes a decrease in the content of unsaturated hydrocarbons in the reaction products; b) increase of the pressure of hydrogen causes an increase in the overall rate of transformation of isopropylbenzene; c) increase of the pressure of hydrogen causes an increase in the yield of benzene and decreases in the yields of toluene and ethylbenzene; in the gaseous reaction products, the propane content increases sharply and the methane content diminishes; d) rise of temperature greatly accelerates the process; e) it was shown that the liquid reaction products include not only benzene, toluene, and ethylbenzene, but also propylbenzene, biphenyl, and naphthalene (at low hydrogen pressures).

The effect of the pressure of hydrogen on the rate and direction of the homogeneous destructive hydrogenation of isopropylbenzene can be qualitatively explained on the basis of an examination of a general scheme of chain reactions as the mechanism of the reaction studied, although the data obtained are of course insufficient for the establishment of many details of this scheme.

The first act of the process is the decomposition of isopropylbenzene [4]:

$$C_6H_5CH(CH_3)_2 \longrightarrow C_6H_5\dot{C}HCH_3 + \dot{C}H_3 \qquad (1)$$

The radicals formed react with molecular hydrogen:

$$C_6H_5\dot{C}HCH_3 + H_2 \longrightarrow C_6H_5CH_2CH_3 + \dot{H} \qquad (2)$$

$$\dot{C}H_3 + H_2 \longrightarrow CH_4 + \dot{H} \qquad (3)$$

The atomic hydrogen then reacts with isopropylbenzene and with ethylbenzene:

$$C_6H_5CH(CH_3)_2 + \dot{H} \longrightarrow C_6H_5\dot{C}(CH_3)_2 + H_2 \qquad (4)$$

and / or $C_6H_5CH(CH_3)(\dot{C}H_2) + H_2$;

$$C_6H_5CH(CH_3)_2 + \dot{H} \longrightarrow \dot{C}_6H_5 + C_3H_8 \qquad (5')$$

and / or $C_6H_6 + \dot{C}_3H_7$; $(5'')$

$\dot{C}_6H_5 + H_2 \longrightarrow C_6H_6 + \dot{H}$ (6). $\dot{C}_3H_7 + H_2 \longrightarrow C_3H_8 + \dot{H}$ (7)

$$C_6H_5C_2H_5 + \dot{H} \longrightarrow C_6H_5\dot{C}HCH_3 + H_2 \qquad (8)$$

and / or $C_6H_5CH_2\dot{C}H_2 + H_2$

$$C_6H_5C_2H_5 + \dot{H} \longrightarrow \dot{C}_6H_5 + C_2H_6 \qquad (9')$$

and / or $C_6H_6 + \dot{C}_2H_5$. $(9'')$

$$\dot{C}_2H_5 + H_2 \longrightarrow C_2H_6 + \dot{H}. \qquad (10)$$

Reactions (4) and (8) are suppressed by increase in hydrogen pressure. The ethylbenzene formed not only reacts with hydrogen by reaction (9), but also decomposes with formation of toluene:

$$C_6H_5\dot{C}HCH_3 \longrightarrow C_6H_5\dot{C}H_2 + \dot{C}H_3. \quad (11)$$

$$C_6H_5\dot{C}H_2 + H_2 \longrightarrow C_6H_5CH_3 + \dot{H}. \quad (12)$$

The homogeneous destructive hydrogenation of toluene has been examined by us previously [7].

The equations given above characterize essentially only the participation of hydrogen in the process under consideration. The complete scheme of the chain mechanism includes also the interaction among themselves of all of the radicals formed (recombination reactions and their interactions with all of the substances in the reaction sphere. An examination of the above equations shows that increase of hydrogen pressure will lead to increase in the concentration of atomic hydrogen; the interaction of the atomic hydrogen with isopropylbenzene molecules (and also with ethylbenzene and toluene) will therefore be accelerated with increase in the yield of benzene and acceleration of the overall transformation of isopropylbenzene. For the same reason the yield of propane will also be increased.

We remarked above that in our experiments at low initial hydrogen pressure there was some increase in the yields of ethylbenzene and toluene as compared with experiments in which hydrogen was absent. It is possible that this is to be explained by the occurrence of the following reactions [10]:

$$C_6H_5C_2H_5 + \dot{H} \longrightarrow C_6H_5\dot{C}H_2 + CH_4 \quad (13')$$

$$\text{or } C_6H_5CH_3 + \dot{C}H_3 \quad (13'')$$

and correspondingly

$$C_6H_5CH(CH_3)_2 + \dot{H} \longrightarrow C_6H_5\dot{C}_2H_4 + CH_4 \quad (14')$$

$$\text{or } C_6H_5C_2H_5 + \dot{C}H_3 \quad (14'')$$

but this matter requires further investigation.

SUMMARY

1. The homogeneous destructive hydrogenation of isopropylbenzene high pressures of hydrogen was investigated.

2. It was shown that increase in the pressure of hydrogen accelerates the transformation of isopropylbenzene, greatly increases the yield of benzene, reduces the yields of toluene and ethylbenzene, and brings about an increase in the propane content of the gaseous reaction products.

3. An explanation is advanced for the observed effects of the pressure of hydrogen on the rate and direction of the homogeneous destructive hydrogenation of isopropylbenzene.

LOW-TEMPERATURE ALKYLATION OF α- AND β-OLEFINS WITH TERTIARY ALKYL HALIDES IN PRESENCE OF ZINC CHLORIDE

A. P. Meshcheryakov, E. I. Erzyutova, and A. D. Petrov

The reaction of catalytic alkylation of olefins with alkyl halides was discovered in 1878 simultaneously by Eltekov [1] and by Lermontova [2], who worked in Butlerov's laboratory. Only in the last decade has the use of this reaction been developed by Russian and foreign investigators, who have used it (and also the copolymerization reaction of 2-methylpropene and 2-butene) mainly for the synthesis of 2,2,3-trimethylbutane.

Our object in the present investigation was the further study of this reaction and the application of it to the preparation of alkylation products containing branched olefins ranging from C_8 to C_{16} and containing tertiary and quaternary carbon atoms. We studied the alkylation of 2-butene, 2-methyl-2-butene, 1-hexene, and 1-octene with tert-butyl chloride, 2-chloro-2,3-dimethylbutane, 2-chloro-2,3,3-trimethylbutane, and 4-chloro-4-propylheptane.

The investigation of the first of these reactions — the alkylation of 2-butene with tert-butyl chloride — already showed that, in spite of the low alkylation temperature (room temperature), there occurred not only the addition reaction — already noted by Lvov [3] and by Kondakov [4] and resulting in the formation of 3,4,4-trimethyl-2-pentene (25 % yield) — but also the formation by isomeric change of 2,3,3-trimethyl-1-pentene (26%) and 2,3,4-trimethyl-2-pentene (46%).

The formation of the first of these hydrocarbons can be described by reactions of addition and elimination of HCl in accordance with the rules of Markovnikov [5], Vagner [6], and Zaitsev [7] — reactions that are related to the replacement of chlorine by a methyl group as noted by Vagner [8], Favorsky [9], and Brown and Fletcher [10, 11].

(Scheme 1)

The same reaction can be represented as addition of H^+ followed by reaction of the resulting ions [12]:

(Scheme 2)

However, we prefer Scheme 1, by means of which we explain all of the reactions that we have studied. The formation of 2,3,4-trimethylpentene is represented as follows:

From the C_9 olefins obtained by the alkylation of 2-methyl-2-butene with tert-butyl chloride, in addition to the main product 2,3,4,4-tetramethyl-2-pentene, formed by the reaction

we isolated also 2,3,3,4-tetramethyl-1-pentene. The formation of this compound can be readily represented on the basis of Scheme 1, i.e. by the reaction:

The formation of other isomeric forms and, in particular, 2,3,3,4,4-pentamethyl-1-hexane by Reaction 3 (see the other alkylation reactions that we have carried out, the results of which are given in the table) can be represented on the basis of Scheme 1, e.g.

Finally, it is of interest to note that in the C_{12} olefin fraction formed in the alkylation of 1-octene with tert-butyl chloride, the following were identified: 2,2-dimethyl-3-decene, 2,2-dimethyl-4-decene, and 2,3-dimethyl-3-decene. Hence, here there occurred partial isomerization and conversion of a hydrocarbon with a quaternary carbon into one with two tertiary carbons. On the other hand, a hydrocarbon with a tertiary carbon in which there were propyl groups instead of methyls - 4,4-dipropyl-5-decene (Reaction 4, table)-- did not undergo isomerization of this kind. An attempt to alkylate 2,3-dimethyl-2-butene with tert-butyl chloride was not successful; only 2-chloro-2,3--dimethylbutane was formed (by addition to the dimethylbutene of HCl eliminated from tert-butyl chloride) together with very small amounts of di- and tri-isobutylenes. As can be readily understood, we did not succeed also in the alkylation of 2,3-dimethyl-2-butene with 2-chloro-2,3-dimethylbutane.

EXPERIMENTAL

Alkylation. The alkylation was carried out in glass apparatus. The reaction mixture consisted of olefin and alkyl halide (equivalent amounts) together with $ZnCl_2$ (10% on the weight of olefin taken). The reaction mixture was shaken for 6-8 hours each day at room temperature over a period of 10-12 days. The alkylation product was then decanted from zinc chloride, washed with a saturated solution of potassium carbonate, dried with calcium chloride, and fractionated. In the first fractionation unchanged olefin and alkyl halide were separated; the amount recovered unchanged was about 50% in all of the syntheses. The remaining mixture of alkyl halides and olefins formed in the reaction was then treated with hot caustic potash solution and was fractionated several times through an 18-

plate column. About thirty experiments were carried out on the alkylation of 2-butene with tert-butyl chloride, and 500 g of a C_8 olefin fraction was obtained, b.p. 108-116°, the yield being 35-39% (calculated on the basis of the amounts of 2-butene and tert-butyl chloride that reacted).

The fraction had b.p. 108-116°, d_4^{20} 0.7367; and n_D^{20} 1.4225

	Found %:	C 85.69; H 14.32
C_8H_{16}.	Calculated%:	C 85.63; H 14.37

Ozonization. Ozonized oxygen (about 6% ozone) was passed for 14 hours at 4 liters per hour through a solution of 10 g of C_8 olefins in 30 ml of chloroform. Altogether, 50 g of C_8 olefins was ozonized in portions. The ozonides were hydrolyzed with water and 10% hydrogen peroxide. The following ozonization products were isolated: 1) Acetone, identified a) as the semicarbazone, m.p. 183-184° and b) as the 2,4-dinitrophenylhydrazone, m.p.124.5° (a mixture test gave 124-125°; the literature [13] gives 126°). 2) 3 methyl-2-butanone, identified as its semicarbazone, m.p. 110-111.5° (a mixture test gave 110-111.5°; the literature [13] gives 113°). 3) Pinacolone, identified as its semicarbazone, m.p. 152-153° (a mixture test gave 153-154°; the literature [13] gives 157°). 4) 3,3--Dimethyl-2-pentanone, identified as its semicarbazone, m.p. 138-139° (the literature [14] gives 136-138°). In order to provide a sample for a mixture melting test, the ketone was synthesized from 1,1-dimethylpropylmagnesium chloride and acetyl chloride; the melting point of the semicarbazone of this ketone was 139-140°, and the melting point of the mixture was also 139-140°.

Analysis of the semicarbazone prepared from 3,3-dimethyl-2-pentanone:

	Found %:	N 23.76
$C_8H_{17}ON_3$.	Calculated%:	N 24.5

Acid ozonization products isolated were: formic acid (identified by the calomel method) and acetic acid (identified by the silver salt):

	Found %.	Ag 64.11
$C_2H_3O_2Ag$.	Calculated%:	Ag 64.63
	Found	M 59 (titration)
$C_2H_4O_2$.	Calculated	M 60

The C_8 olefin fraction (400 g) was hydrogenated in an autoclave over Bag's nickel catalyst; 100 g of the product was analyzed by the Raman spectrum method, and 300 g was demethylated, fractionated, and then analyzed spectrographically. The results confirmed the conclusions about the structures of the C_8 olefins which we had reached on the basis of the ozonization results.

The C_8 olefin fraction obtained by the alkylation of 2-methyl-2-butene with tert-butyl chloride had b.p. 128-134°, d_4^{20} 0.7550; n_D^{20} 1.4293.

	Found %:	C 85.61; H 14.45
C_8H_{16}.	Calculated%:	C 85.63; H 14.37

Ozonization of the C_8 olefins was carried out under the conditions indicated above. Formic acid was identified in the acid fraction, and acetone and pinacolone in the neutral fraction. Also, in the higher fraction of the oxidation products, b.p. 150-157°, 3,3,4-trimethyl-2-pentanone was identified (as semicarbazone, m.p. 147-148°; the literature [15] has 146.5-148.5°). In order to provide material for a mixture melting test, 3,3,4-trimethyl-2--pentanone was synthesized by hydrogenation over platinum of 3,3,4-trimethyl-4-penten-2-one, obtained by Kondakov's method from 2,3-dimethyl-2-butene and acetyl chloride in presence of zinc chloride. The semicarbazone of the 3,3,4-trimethyl-2-pentanone synthesized in this way melted at 148-149°.

	Found%:	N 22.45
$C_8H_{19}ON_3$.	Calculated%:	N 22.66

A mixture test on the semicarbazones of the ketone synthesized by us and the ketone obtained by ozonization of the C_8 olefins showed a melting point of 147.5-149°.

In the analysis of the ozonization products of the C_{12} fraction obtained by the alkylation of 1-octene by tert--butyl chloride, the only substance identified (by the method indicated above) in the neutral fraction was 3-methyl--2-butanone. By fractional precipitation of the acids as silver salts we isolated a C_7 acid (heptanoic), a C_8 acid

TABLE

Reaction No.	Tertiary alkyl halide	Olefin	Isolated alkylation products		
1			1) 	2) 	3) 	2-Chloro-2,3-dimethylbutane	2-Butene	3,4,4,5-Tetramethyl-2-hexene	2,3,4,4-Tetramethyl-2-hexene	2,3,4,5-Tetramethyl-3-hexene
2				—	—
	2-Chloro-2,3-dimethylbutane	2-Methyl-2-butene	2,3,4,4,5-Pentamethyl-2-hexene	—	—
3			1) 	2) 	
	2-Chloro-2,3,3-trimethylbutane	2-Butene	3,4,4,5,5-Pentamethyl-2-hexene	2,3,3,4,4-Pentamethyl-1-hexene	
4				—	
	4-Chloro-4-propylheptane	1-Hexene	4,4-Dipropyl-5-decene		

(probably a mixture of hexanoic and 3,3-dimethylbutyric acids), and a C_5 acid (pivalic acid).

	Found%:	Ag 45.91
$C_7H_{13}O_2Ag$.	Calculated%:	Ag 45.51
	Found%:	Ag 47.79
$C_6H_{11}O_2Ag$.	Calculated%:	Ag 48.38
	Found%:	Ag 51.7
$C_5H_9O_2Ag$.	Calculated%:	Ag 51.61

The heptanoic acid was also converted into its amide, m.p. 91.5-92.5° (the literature give 96° [16]).

In the subsequent alkylation experiments (Reactions 1-3, table), in the analysis of the C_{10} and C_{12} olefin fractions we met the problem of identifying the same ketones (and also formic and acetic acids) as in the experiments described above. We shall therefore omit descriptions of the experiments and confine ourselves to the alkylation results obtained, which are given in the table. These results show that in the first reaction two additional isomeric hydrocarbons are obtained, in the second reaction there were none, and in the third reaction there was one. The first of the isomeric C_{10} olefins obtained in Reaction 1, 2,3,4,4-tetramethyl-2-hexene, is a form whose formation could be predicted from the laws of Scheme 1, i.e. successive addition and elimination of HCl and replacement of chlorine by methyl. The formation of the third C_{10} olefin, 2,3,4,5-tetramethyl-3-hexene, could not have been predicted, but its formation is readily explained by Scheme 2 as the result of the addition of H^+ to 2,3,4,4-tetramethyl--2-hexene and subsequent isomerization of a tertiary amyl group into a secondary amyl group. The absence of an isomeric form in Reaction 2 under the low-temperature conditions of alkylation studied and the formation of only one isomeric hydrocarbon in Reaction 3 are probably to be explained by reduced possibilities of isomerization arising from steric difficulties.

In conclusion, we will consider the C_{16} olefin fraction obtained by the alkylation of 1-hexene with 4-chloro--4-propylheptane (Reaction 4, table); b.p. 93-97° (2 mm), d_4^{20} 0.8137; n_D^{20} 1.4480. In the ozonization of this fraction no neutral products were found. Acid products isolated were: a liquid acid, b.p. 175-180°, and a crystalline acid. The latter was filtered off, and the silver salt of the liquid acid was prepared.

	Found%:	Ag 51.41
$C_5H_9O_2Ag$.	Calculated%:	Ag 51.61

Analysis of the crystalline acid (2,2-dipropylvaleric acid):

	Found M 183 (titration)	
$C_{11}H_{22}O_2$.	Calculated M 186	
	Found%:	Ag 36.00
$C_{11}H_{21}O_2Ag$.	Calculated%:	Ag 36.22

The crystalline acid was converted into its amide: 0.35 g of the acid and 5 ml of thionyl chloride were refluxed together for 30 minutes, and the mixture was then poured into 15 ml of concentrated ammonia cooled in ice. The precipitate was filtered off and recrystallized from dilute alcohol. It melted at 58-59° (for 2,2-dipropylvaleramide the literature [17] gives m.p. 69-70°).

4,4-Dipropyl-5-decene (8.5 g) was hydrogenated in pentane solution over nickel at 180-200° and an initial pressure of 80 atm. The product was 4,4-dipropyldecane, b.p. 119-121° (15 mm), d_4^{20} 0.7951; n_D^{20} 1.4398, (the literature [18] gives b.p. 124-126° (16 mm), d_4^{20} 0.7879; n_D^{20} 1.4398).

SUMMARY

1. A study was made of low-temperature alkylation of olefins with tertiary alkyl halides in presence of zinc chloride, and the relationship between the structure of the reactants and the character of the side reactions — isomeric changes accompanying the reaction of addition of chloroalkanes to alkenes — was elucidated.

2. It was established that in the alkylation of 2-butene, both with tert-butyl chloride and with 2-chloro-2,3--dimethylbutane, the octene and decene isomers predicted by theory are formed.

3. In the alkylation of 2-methyl-2-butene with tert-butyl chloride, only one isomeric form of the expected structure is formed (2,3,3,4-tetramethyl-4-heptene), and in alkylation with 2-chloro-2,3,3-trimethylbutane, again only one isomeric form is formed (2,3,3,4,4-pentamethyl-1-hexene).

4. In the alkylation of 2-methyl-2-butene with 2-chloro-2,3-dimethylbutane, only the addition reaction occurs, leading to the formation of 2,3,4,4,5-pentamethyl-2-hexene with absence of isomeric change.

5. It was shown that, whereas in the alkylation of 1-octene with tert-butyl chloride both 2,2-dimethyl-3-decene and 2,3-dimethyl-3-decene are formed (i.e. partial isomerization of a hydrocarbon with a quaternary carbon atom occurs), in the alkylation of 1-hexene with 4-chloro-4-propylheptane only 4,4-dipropyl-5-decene is obtained (i.e. a hydrocarbon with a quaternary carbon atom in which propyl groups replace methyl groups no longers undergoes isomerization).

POLYORGANOALUMINOSILOXANES

K. A. Andrianov and T. N. Ganina

The first information on polyorganometallosiloxanes appeared in 1947. It was observed that organosilicon compounds containing hydroxyl groups form polymeric compounds with multivalent metals and their hydroxides, and it was shown that the chains of the polymers contain metallosiloxane groups [1]. The following scheme of reaction was proposed for the formation of polyorganoaluminosiloxanes:

$$6HOSiR_2 \cdot OSiR_2OH + 2Al \rightarrow 2(HOSiR_2OSiR_2O)_3Al + 3H_2 \qquad (1)$$

It was later found [2] that triethylsilanol reacts with aluminum with formation of nonaethylaluminoxytrisiloxane [author's nomenclature] in accordance with the scheme:

$$6(C_2H_5)_3SiOH + 2Al \rightarrow 2[(C_2H_5)_3SiO]_3Al + 3H_2 \qquad (2)$$

Further investigations showed that polyorganometallosiloxanes can be prepared by the cohydrolysis of alkyl (or aryl) halosilanes and salts of multivalent metals and by metathetical reactions between hydrolysis products of organosilicon monomers and salts of multivalent metals.

As will be seen from Equation 1, polyorganoaluminosiloxanes consist of molecules having chains of the following structure:

They contain $-\overset{|}{\underset{|}{Si}}-O-$ and $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkages.

It has been established by the study of various organosilicon compounds that the $-\overset{|}{\underset{|}{Si}}-O-\overset{|}{\underset{|}{Si}}-$ linkage is capable of undergoing scission under the action of acid agents. For example, the $-\overset{|}{\underset{|}{Si}}-O-\overset{|}{\underset{|}{Si}}-$ linkage of hexamethyldisiloxane is broken by the action of 20% oleum or a mixture of sulfuric acid and ammonium chloride or fluoride [3]. The available data on the action of acid reagents on the $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkage indicate that, even in such complex compounds as aluminosilicates, this linkage undergoes scission under the action of hydrochloric and other acids. In polyorganoaluminosiloxanes the $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkage differs considerably from that found in aluminosilicates, the oxygen being bound to silicon atoms carrying two or three organic radicals. This circumstance must naturally affect the stability of the $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkage to acid scission. The organic radicals (CH_3, C_2H_5, C_6H_5) replacing the oxygen bonds of silicon in polyorganoaluminosiloxanes weaken the electrophilic character of silicon, which must lead to a strengthening of the electrophilic character of the aluminum atom in the $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkage and therefore to an increase in the tendency of this linkage to undergo scission under the action of acid.

It is therefore of great interest to prepare polyorganoaluminosiloxanes and subject them to a scission reaction with the object of studying the stability of their $-\overset{|}{\underset{|}{Si}}-O-Al-$ linkages – as compared with those of aluminosilicates – to the action of aqueous hydrochloric acid. For this purpose we synthesized a polymer containing aluminum chemically bound to silicon atoms through oxygen, namely, polyaluminoxytetra(dimethylphenyldisiloxane) [author's nomenclature]. The synthesis was effected by the cohydrolysis of dichlorodimethylsilane, trichlorophenylsilane, and aluminum chloride in an alkaline medium:

$$R_2SiCl_2 + R'SiCl_3 + AlCl_3 \xrightarrow[NaOH]{H_2O} [OR_2SiOSiR']_4-O-\overset{|}{\underset{|}{Al}}-O-$$

We also synthesized the monomeric compound, nonaethylaluminoxytrisiloxane by dissolving aluminum in triethylsilanol:

$$6(C_6H_5)_2SiOH + 2Al \rightarrow 2[(C_6H_5)_2SiO]_3Al + 3H_2.$$

Our investigation of the scission of $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages in polyaluminoxytetra(dimethylphenyldisiloxane) and nonaethylaluminoxytrisiloxane by means of hydrochloric acid was carried out in conjunction with comparative measurements on the natural mineral kaolin, which, according to Vernadsky [4], has the following formula:

It is known from the literature [5] that treatment of kaolin with 10 % hydrochloric acid in a boiling water bath for ten hours results in the rupture of

$-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages.

In our experiments the scission of the

$-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkage in nonaethylaluminoxytrisiloxane, polyaluminoxytetra (dimethylphenyldisiloxane), and kaolin was effected with hydrochloric acid (10%, 20%, and 30%) at 96°. The experimental results, which are given in Fig. 1, show that in a one hour treatment with 10% hydrochloric acid the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages in polyaluminoxytetra(dimethylphenyldisiloxane) are ruptured to the extent of 79%, and those in kaolin to the extent of 90.8%. After five hours the respective figures are 65, 90.5, and 100%, after ten hours the extent of scission is 70% for polyaluminoxytetra(dimethylphenyldisiloxane) and 91% for nonaethylaluminoxytrisiloxane, and after 22 hours the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages in polyaluminoxytetra(dimethylphenyldisiloxane) are ruptured only to the extent of 79%.

Fig. 1. Scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkage with 10% hydrochloric acid: 1 - polyaluminoxytetra(dimethylphenyldisiloxane) 2 - nonaethylaluminoxytrisiloxane; 3 - kaolin

Fig. 2. Scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkage with 20% hydrochloric acid: 1 - polyaluminoxytetra (dimethylphenyldisiloxane) 2 - nonaethylaluminoxytrisiloxane; 3 - kaolin

The results presented in Fig. 2 show that, under the action of 20% hydrochloric acid for one hour, the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages in polyaluminoxytetra(dimethylphenyldisiloxane) are broken down to the extent of 59.9%, those in nonaethylaluminoxytrisiloxane to the extent of 86.7% and those in kaolin to the extent of 87.8%. After five hours the corresponding figures are 69.0, 98.7, and 100%, and after ten hours the extent of scission is 72.0% for polyaluminoxytetra (dimethylphenyldisiloxane) and 99.2% for nonaethylaluminoxytrisiloxane. The results presented in Fig. 3 show that, under the action of 30% hydrochloric acid for one hour, the $-\overset{|}{Si}-O-\overset{|}{Al}-$ -linkages in polyaluminoxytetra(dimethylphenyldisiloxane) are broken down to the extent of 67.2%, those in nonaethylaluminoxytrisiloxane to the

extent of 93 1%, and those in kaolin to the extent of 100%. After ten hours the first two figures are raised to 72 and 100%, respectively.

Fig. 3. Scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage with 30% hydrochloric acid: 1 - polyaluminoxytetra(dimethyl--phenyldisiloxane); 2 - nonaethylaluminoxytrisiloxane; 3 - kaolin

The scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage in polyorganometallosiloxanes proceeds in accordance with the following mechanism: In the first stage a proton reacts with the oxygen of the aluminosiloxane linkage:

An oxonium compound is formed in which the aluminum has enhanced electrophilic activity; it reacts with water with formation of a transitional complex in accordance with the scheme:

The resulting transitional complex breaks down with scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage:

Our results show that the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage in polyaluminoxytetra(dimethylphenyldisiloxane) is more stable to the action of hydrochloric acid than the same linkage in kaolin and nonaethylaluminoxytrisiloxane. This is explained by the fact that when such reagents act upon the molecule of polyaluminoxytetra(dimethylphenyldisiloxane) two reactions occur: first the scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage and then the condensation of the silicon-bound hydroxyls with one another. The second reaction leads to the formation of complex molecules of partially broken down molecules of aluminoxytetra(dimethylphenyldisiloxane), and this creates steric difficulties for the development of the first reaction.

EXPERIMENTAL

1. Synthesis of Nonaethylaluminoxytrisiloxane. A mixture of 2.7 g (0.1 mole) of aluminum turnings, 39.6 g (0.3 mole) of triethylsilanol, and 0.005 g of mercuric chloride was prepared in a round-bottomed flask fitted with reflux condenser. The mixture was heated until almost the whole of the aluminum had dissolved, the final temperature being 140°. The product was cooled and dissolved in benzene, the solution was filtered, and benzene was distilled off from a boiling water bath. In order to remove unchanged triethylsilanol, the distillation was completed under reduced pressure (85° at 5 mm). The product was 40 g of nonaethylaluminoxytrisiloxane, obtained as a crystalline substance.

$C_{18}H_{45}O_3Si_3Al$. Found%: Si 19.52; 19.13; Al 6.56; 6.56
Calculated%: Si 20.0 Al 6.7

Found M 424 (cryoscopically in benzene)
Calculated M 420

2. Synthesis of Polyaluminoxytetra(dimethylphenyldisiloxane). Solvent and aqueous alkali in which 6.67 g (0.05 mole) of aluminum chloride was dissolved were introduced into a glass vessel (hydrolyzer) having double walls for the circulation of water and provided with stirrer, thermometer, and dropping funnel. The contents of the vessel were stirred vigorously while a mixture of 51.6 g (0.4 mole) of dichlorodimethylsilane (chlorine content 55.2%; calculated value 54.98%) and 21.14 g (0.1 mole) of trichlorophenylsilane (chlorine content 50.0%; calculated value 50.3%) was added from the dropping funnel. Hydrolysis was for 90 minutes at 13.20°. The oily layer was washed

with water and distilled to remove solvent, leaving liquid polymer in 70% yield.

A portion (33 g) of the liquid polyaluminoxytetra(dimethylphenyldisiloxane) was condensed for three hours at 195-200°, air being blown through the system. A gellike product (25 g) was obtained. It was heated further for 33 hours in a thermostat at 200° in order to convert it into an infusible insoluble solid; it was then finely ground.

$C_{32}H_{44}O_{11\,5}Si_8Al$. Found%: Si 27.02; Al 3.07
Calculated%: Si 26.95; Al 3.12

3. Kaolin. Some kaolin (20 g) was heated at red heat in a muffle furnace for two hours to remove moisture.

$Al_2O_3 \cdot 2SiO_2 \cdot 2H_2O$. Found %: Si 21.8; Al 20.0; H 1.68; C 0.8; O 55.7
Calculated%: Si 21.7; Al 20.93; H 1.55; O 55.81

4. Scission of Nonaethylaluminoxytrisiloxane with Hydrochloric Acid. Hydrochloric acid (100 g) of the desired concentration was introduced into a three-necked flask fitted with hermetically sealed stirrer, thermometer, and reflux condenser. It was heated to 96°, and 1 g of nonaethylaluminoxytrisiloxane was added. The mixture was stirred for 1-2 minutes, and a test sample (2-4 g) was then removed for the determination of aluminum content. The scission reaction was continued for ten hours, further test samples being taken at 1, 3, 5, and 10 hours. The aluminum content of the hydrochloric acid solution was determined colorimetrically by Yoe and Hill's method [6]. The experimental results are given in Tables 1, 2, and 3.

5. Scission of Polyaluminoxytetra(dimethylphenyldisiloxane) with Hydrochloric Acid. The scission of polyaluminoxytetra(dimethylphenyldisiloxane) with hydrochloric acid was carried out by the procedure described above. At the end of the reaction the precipitate of polyaluminoxytetra(dimethylphenyldisiloxane) was filtered from the hydrochloric acid solution, washed twice with 10-ml portions of 1% hydrochloric acid, and then washed with water until there was a negative reaction for chlorine. It was then dried at 105-110° and analyzed for chlorine and silicon. The experimental results are given in Tables 4, 5, and 6.

SUMMARY

1. Polyaluminoxytetra(dimethylphenyldisiloxane) was synthesized.

2. An investigation was made into the scission of the $-\overset{|}{Si}-O-\overset{|}{Al}-$ linkage by the action of aqueous solutions of hydrochloric acid on polyaluminoxytetra(dimethylphenyldisiloxane), nonaethylaluminoxytrisiloxane, and kaolin.

3. A mechanism is proposed for the scission reaction, and it is shown that in polyaluminoxytetra(dimethylphenyldisiloxane) scission of the linkage is more difficult than in nonaethylaluminoxytrisiloxane and in kaolin as the result of the occurence of a second, competing condensation reaction, which results in the formation of stable $-\overset{|}{Si}-O-\overset{|}{Si}-$ linkages and thus limits the extent of the breakdown of polyaluminoxytetra(dimethylphenyldisiloxane).

POLYMERIZATION AND COPOLYMERIZATION OF N-VINYL COMPOUNDS

COMMUNICATION 1. COPOLYMERIZATION OF 9-VINYLCARBAZOLE WITH VINYL ESTERS

S. N. Ushakov and A. F. Nikolaev

In spite of the many investigations that have been devoted to the copolymerization of unsaturated monomers, many vinyl compounds have still received very little study from this point of view. Such compounds include, for example, 9-vinylcarbazole on the one hand, and certain vinyl esters on the other. In particular, there are no data in the literature on the quantitative characterization of the activities of vinyl propionate and butyrate in copolymerization reactions with other unsaturated compounds. The only references, which are given in patents, are to the formation of copolymers with vinyl chloride [1], with abietyl crotonate [2], and with a mixture of vinyl chloride and a maleic ester [3].

The copolymerization of vinyl formate has also received very little study. Descriptions have been given of the preparation of copolymers with ethylene glycol maleic ester [4], acrylonitrile [5], ethylene [6], tetrafluoroethylene [7], and vinyl chloride [8]. Copolymerization constants(r) were determined only for the system vinyl formate - acrylonitrile (r_1 0.04, r_2 3.00).

In the case of vinyl acetate such constants have been determined for its copolymerization with 33 other monomers. Copolymers of vinyl acetate have been prepared in which the second component is ethylene [9], various fluorinated olefins [10], chlorotrifluoroethylene [11], diallyl succinate [12], 2-chloroacrylic acid [13], esters of higher fatty acids (e.g. stearic and others) [14], 1,1-dichloro-2,2-difluoroethylene [15], diethylene glycol maleic ester [16], cyclic disulfides [17], allylidene diacetate [18], allyl carbanilate [19], vinylpyrene [20], diallyl phenylphosphonate [21], diallyl acetal and mixtures of the monomers styrene and acrylic esters [22], acrylonitrile and fumaric acid [23], 3-buten-2-one and methyl acrylate [22], and butadiene and vinylidene chloride [24].

A few papers have been published also on the copolymerization of 9-vinylcarbazole with other vinyl compounds. The most detailed study has been devoted to copolymers with styrene [25, 29, 30] and with a mixture of styrene and acrylonitrile [26]. There are references to the formation of copolymers with fluorinated styrenes (p-fluorostyrene and 3,4-difluorostyrene) [27], isobutene [28], methyl methacrylate [29], vinylpyrene [20], vinyl ethers [30], butadiene [30], and drying oils [31].

A quantitative characterization of the tendency of 9-vinylcarbazole to copolymerize with styrene and with methyl methacrylate was made in 1949 [29]. The values of the copolymerization constants indicate that in reactions with these monomers 9-vinylcarbazole is the less active component.

	r_1	r_2
9-Vinylcarbazole - styrene	0.012	5.5
9-Vinylcarbazole - methyl methacrylate	0.20	2.0

We have studied the copolymerization of 9-vinylcarbazole with the vinyl esters of some organic acids (formic, acetic, propionic, and butyric). It was considered that such an investigation would enable us to characterize the activities of vinyl esters and to form an opinion of their applicability in copolymerizations with other monomers.

The experiments on the copolymerization of 9-vinylcarbazole with vinyl esters were carried out at 100° in presence of 0.5% of benzoyl peroxide. We studied the effect of the composition of the original mixture on the rate of copolymerization. The duration of reaction was nine hours. The results of the experiments are given in Fig. 1 and Table 1.

Rate of Copolymerization. It will be seen from Fig. 1 that, under given conditions, the rate of polymerization of the pure monomers and their mixtures falls in the homologous series of monomers: vinyl formate > vinyl acetate > vinyl propionate > vinyl butyrate. Even very small additions of vinylcarbazole to the vinyl ester sharply

reduce the rate of the process. The reduction in the rate of copolymerization continues down to a definite minimum, which is characteristic for each monomer pair. For example, in the system vinyl formate - vinylcarbazole the yield of copolymer falls from 85 to 11%, whereas in the system vinyl acetate - vinylcarbazole it falls from 65 to 5%.

Fig. 1. Dependence of the rate of copolymerization on the 9-vinylcarbazole content of the original mixture: 1 - vinyl formate - vinylcarbazole; 2 - vinyl acetate - vinylcarbazole; 3 - vinyl propionate - vinylcarbazole; 4 - vinyl butyrate - vinylcarbazole.

With further increase in the vinylcarbazole content of the original mixture, the rate of the process increases. The minimum rate of polymerization depends on the nature of the monomer, increasing with increase in the length of the carbon chain of the acid residue of the ester and moving in the direction of a higher vinylcarbazole content in the original mixture.

In the systems vinyl propionate - vinylcarbazole and vinyl butyrate - vinylcarbazole under the time and temperature conditions of our experiments, there are definite limits of the ratio of components within which no polymerization whatever of the monomers occurs; the rate of copolymerization falls almost to zero. It would appear that vinylcarbazole, owing to the effect of the numerous double bonds of the molecule on the vinyl group, is more reactive as a monomer than vinyl esters, but the radicals of vinyl esters are considerably more reactive than vinylcarbazole. The effect of the number of double bonds in the molecule on the reactivities of some vinyl compounds was shown by Koton and Kiseleva [32], who studied the polymerization of vinylnaphthalenes. It was found that the reactivity of vinylnaphthalenes falls with reduction in the number of double bonds in the molecule. Completely hydrogenated vinylnaphthalene scarcely polymerizes at all.

As a result of the considerable rate at which the addition reaction occurs between vinylcarbazole molecules and vinyl ester radicals, polmetic vinylcarbazole radicals (the name of a polymeric radical is determined by the monomer attached at the end of the molecule) of low activity are formed even at low vinylcarbazole concentrations. Hence, the reduction in the rate of the reaction of the polymeric vinylcarbazole radical with vinyl ester molecules (there are few vinylcarbazole molecules owing to concentration conditions), as compared with the rate of addition of vinyl ester molecules to the corresponding radicals, results in a reduction in the overall rate of the copolymerization.

These considerations enable us to infer that copolymers obtained from such systems should have a lower molecular weight than polymers obtained from pure monomers. It is known that the degree of polymerization depends on the ratio of the rates of chain propagation and of chain termination, so that reduction in the rate of chain propagation must lead to a reduction in the molecular weight of the copolymers. After the attainment of a definite minimum of the rate of copolymerization (depending on the ratio of the rates of reaction between a vinylcarbazole radical and the vinyl ester and between the vinyl ester radical and the corresponding vinyl ester), the rate of copolymerization begins to rise and attains the rate of separate polymerization owing to the increase of the concentration of vinylcarbazole in the original mixture and the greater probability of the reaction between the polymeric vinylcarbazole radical and vinylcarbazole molecules. It follows also that the molecular weight of the copolymers must rise correspondingly.

The lowering observed in the rate of copolymerization of vinylcarbazole with vinyl esters is to be explained by the increase in the rate of interaction of vinyl ester radicals with vinylcarbazole in the series vinyl butyrate > vinyl propionate > vinyl acetate > vinyl formate and the consequent formation of polymeric vinylcarbazole radicals of low activity.

Copolymerization Constants. All of the systems investigated were characterized by copolymerization constants r_1 and r_2 (Table 2). These were determined graphically from the experimental data presented in Table 1.

Examining the values of $r_1 = K_{M_1 M_1} / K_{M_1 M_2}$ and $r_2 = K_{M_2 M_2} / K_{M_2 M_1}$ we see that vinylcarbazole

adds to its own radical and to the radical of the vinyl ester considerably more rapidly than the vinyl ester does to its own radical and to the vinylcarbazole radical, but in the series of monomers – vinyl formate, vinyl acetate, vinyl propionate, vinyl butyrate – there is a gradual increase in the tendency for addition of vinylcarbazole monomer to the vinyl ester radical (reduction of r_1) and of the vinylcarbazole radical to vinyl ester monomer. This conclusion is confirmed by the increase in the alternation effect, determined by the product $r_1 \cdot r_2$. The lower this product, the more significant is the alternation effect. In the limiting cases the product $r_1 \cdot r_2$ is equal to zero or unity. As is known, in the first case there is true alternation, and in the second there is no alternation.

It will be seen from Table 2 that change of temperature from 65° to 100° (by 35°) causes some increase in both constants for the system vinyl acetate - vinylcarbazole. This shows that with rise in temperature both monomers become more active towards their "own" radicals. There is little change in the ratio of the constants. It may be inferred that the composition of the copolymers does not vary greatly with variation in the copolymerization temperature.

Composition of the Copolymers. In the copolymerization of two or more monomers, the product is a mixture of polymer molecules differing both in composition and in chain length. Some pairs of monomers form copolymers that are fairly homogeneous in composition, whereas other copolymers are extremely nonuniform. The compositions of vinyl acetate - vinylcarbazole copolymers were calculated by a method that one of us has used previously [33]. The original equations are those of Gindin, Abkin, and Medvedev [34]:

$$\frac{M_1}{M_1^0} = \left(\frac{M_2}{M_2^0}\right)^K \qquad K = \frac{r_1 M_1^0 / M_2^0 + 1}{r_2 + M_1^0 / M_2^0}.$$

The calculated integral and differential compositions are presented in Figures 2 and 3.

TABLE 2

Copolymerization Constants r_1 and r_2

System	Temperature (°C)	r_1	r_2	$r_1 r_2$
Vinyl formate - vinylcarbazole	100	0.196 ± 0.004	4.220 ± 0.160	0.827
Vinyl acetate - vinylcarbazole	100	0.152 ± 0.013	3.020 ± 0.240	0.465
Vinyl acetate - vinylcarbazole	65	0.126 ± 0.032	2.680 ± 0.100	0.338
Vinyl propionate - vinylcarbazole	100	0.076 ± 0.018	1.680 ± 0.140	0.128
Vinyl butyrate - vinylcarbazole	100	0.059 ± 0.020	1.280 ± 0.060	0.074

The integral-composition diagram shows the change in the mean composition of the copolymer in the course of the process, and it enables us to select the correct initial ratio of components for the preparation of a copolymer of a particular composition. Any substantial change in the composition of the copolymer occurring in the course of the copolymerization reaction, and often observed at a fairly high progress of reaction, can lead to a deterioration in the properties of the product. The differential-composition diagram provides the possibility of knowing the composition of the copolymer at any moment during the copolymerization and therefore enables us to prepare a more uniform product having better physicomechanical characteristics.

It will be seen from Figures 2 and 3 that, in the copolymerization of vinyl acetate with vinylcarbazole, the composition of the copolymer varies greatly with the degree of conversion. The greater the amount of the more active component in the original mixture, the less the variation in the composition of the copolymers. However, even with a molar ratio of vinyl acetate to vinylcarbazole of 1 : 4, the composition of the copolymer begins to vary greatly when the degree of conversion attains 65%. By application of the diagrams of integral and differential composition for this pair of monomers, it is possible to find a method of preparing copolymers that are more uniform in composition.

Distribution of the Monomeric Units in the Copolymer Macromolecule. A knowledge of the values of the copolymerization constants r_1 and r_2 enables us also to calculate the distribution of monomers in macromolecules of different composition from the formulas proposed by Gindin, Abkin, and Medvedev [34]. The relevant results cal-

culated for pairs vinyl acetate-vinylcarbazole are presented in Table 3.

Fig. 2. Diagram of the integral compositions of copolymers calculated for the original mixtures of different compositions and for various degrees of conversion. The figures on the curves show the vinyl acetate contents of the original mixtures in moles per mole of vinylcarbazole (o-calculated values; +- experimental values)

Fig. 3. Diagram of the differential composition of colpolymers calculated for original mixtures of different compositions and for various degrees of conversion. The figures on the curves show the vinyl acetate contents of the original mixtures in moles per mole of vinylcarbazole.

TABLE 3

Distribution of Monomers in the Macromolecules of Copolymers of Vinyl Acetate (M_1) and Vinylcarbazole (M_2)

Initial molar ratio M_1^0/M_2^0	Composition of copolymer (mole %)		Percentage of linkages in macromolecule				Mean length of unit	
	M_1	M_2	M_1-M_1	M_1-M_2	M_2-M_1	M_2-M_2	$\bar{L}_{M_1}$	$\bar{L}_{M_2}$
50.00	88.88	11.12	78.67	10.35	10.35	0.63	8.06	1.06
10.10	66.67	33.33	40.00	26.10	26.10	7.80	2.53	1.30
5.04	53.35	46.65	22.80	29.70	29.70	17.80	1.77	1.60
2.03	33.30	66.70	7.94	26.15	26.15	39.76	1.30	2.52
1.00	23.10	76.90	2.94	19.30	19.30	58.46	1.15	4.03
0.51	13.25	86.75	0.97	12.50	12.50	74.03	1.08	6.93
0.25	8.20	91.80	0.27	7.10	7.10	85.53	1.04	13.05

It will be seen from Table 3 that, when there is a great (e.g. 50-fold) excess of vinyl acetate in the original mixture, M_1-M_1 links predominate in the macromolecule chain, but with increase in the vinylcarbazole content of the original mixture the number of M_2-M_2 links increases at the expense of M_1-M_1 links; when there is an excess of vinylcarbazole M_2-M_2 links tend to predominate. At a molar ratio of vinyl acetate to vinylcarbazole of 1:4 and a low degree of conversion, M_1 - M_1 links are almost absent, and chain growth occurs mainly by the formation of M_1-M_2 links, and to some extent M_1-M_2 and M_2-M_2 links. Correspondingly, the mean length of the unit $\bar{L}_{M_2}$ is increased as a result of decrease in the mean length of the unit $\bar{L}_{M_1}$.

EXPERIMENTAL

Preparation of the Starting Materials. All of the monomers, with the exception of vinyl formate, were obtained from the Leningrad Polymerization Plastics Research Institute. 9-Vinylcarbazole was recrystallized three times from methanol and once from vinyl acetate; it was obtained as a white crystalline powder, m.p. 64° [bromine value 92.4 (calculated 92.5); nitrogen content 7.22% (calculated 7.25%)]. We found that the purest preparation of vinylcarbazole was obtained when it was recrystallized from vinyl acetate. Freshly recrystallized vinylcarbazole

was used in the experiments. Vinyl formate was synthesized by the liquid-phase method from anhydrous formic acid and acetylene at 40° in presence of freshly prepared 2% mercury phosphate as catalyst. The reaction product was fractionated through a laboratory column, the vinyl formate fraction boiling in the range 45.0-46.0° (760 mm) being collected. Vinyl formate and the other vinyl esters were distilled before use, and fractions collected over a narrow boiling range (0.2°) were used in the experiments. The properties of the esters are given in Table 4. Benzoyl peroxide was purified by precipitation with methanol from its solution in chloroform and by precipitation with distilled water from its solution in acetone; it was dried in a vacuum at room temperature. The benzoyl peroxide was analyzed by a method that has been verified by Kasterina and Itkina [35]. The sample used contained 99.5% of benzoyl peroxide and melted at 103.5°.

TABLE 4

Properties of Vinyl Esters

Name of ester	B.p.(° C, 760mm)	Properties		Monomer content(%)
		d_{20}^{20}	n_D^{20}	
Vinyl formate	43.0	0.9594	1.3347	99.80
Vinyl acetate	73.0	0.9343	1.3958	99.98
Vinyl propionate	94.8	0.9170	1.4028	99.50
Vinyl butyrate	116.5	0.9018	1.4092	99.70

Copolymerization Procedure. The copolymerization of vinylcarbazole with vinyl esters was carried out in the mass in 5-ml glass ampoules in an atmosphere of air, definite amounts of components being taken in order to maintain identical reaction conditions. Before use, the ampoules were treated for 24 hours with warm chromic acid mixture, washed with distilled water, steamed for three hours, and dried in a thermostat at 120°. Benzoyl peroxide was used as polymerization initiator.

The components were loaded into the ampoule in the following order: first the necessary amount of vinylcarbazole, then a weighed amount of benzoyl peroxide, and finally, after the solids had been added, a measured amount of the freshly distilled vinyl ester was added from a microburet. All the weighings were accurate within 0.0001 g. The copolymerization was carried out by placing the ampoules containing the monomer mixtures (amounting to 2 g) in a thermostat and shaking them continuously at a temperature of 100 ± 0.1°. After definite intervals of time ampoules were taken out of the thermostat and cooled in solid carbon dioxide to stop the process rapidly. The experiments for the determination of the copolymerization constants were taken to a low degree of conversion.

Isolation of Copolymers. The cooled ampoules were opened, and their contents were covered with benzene (chloroform was used for copolymers of vinylcarbazole and vinyl formate). The copolymer solutions were transferred to 100-ml flasks. The ampoules were washed with fresh portions of solvent until a drop of solvent taken from the ampoule did not produce a turbidity in petroleum ether due to precipitation of copolymer.

The polymer solution, diluted to the necessary concentration with solvent, was added dropwise with continuous stirring to a large volume of petroleum ether. The concentration of polymer necessary was determined by the precipitation conditions (the copolymer should separate in the form of light flocks, and not as conglomerates that are difficult to wash), and it depended on the composition of the copolymer and the extent of polymerization. After the precipitation of the whole of the copolymer, the solution was poured off and the precipitate was washed several times by decantation with fresh portions of precipitant. The copolymer was then again dissolved, and its precipitation was carried out according to the scheme described. The doubly reprecipitated copolymer was collected on a weighed filter and washed several times with warm petroleum ether. The filter with the precipitate was dried in the air for two hours and then placed in a vacuum cupboard. The copolymers were dried to constant weight at 60° at a residual pressure of 3-5 mm.

Analysis of the Copolymers. All of the copolymers were analyzed for nitrogen by the semimicro Kjeldahl method [36]. The compositions of the copolymers were calculated from their yields and nitrogen contents.

SUMMARY

1. Previously undescribed copolymers of 9-vinylcarbazole and vinyl esters of organic acids (formic, acetic, propionic, and butyric) were prepared by the method of mass polymerization.

2. It was shown that for identical reaction conditions the rate of copolymerization of a vinyl ester falls as the chain length of its acid residue increases.

3. Copolymerization constants were determined for the reactions of vinyl formate, vinyl acetate, vinyl propionate, and vinyl butyrate with 9-vinylcarbazole. The differential and integral compositions of copolymers formed by 9-vinylcarbazole with vinyl acetate were calculated.

4. The considerable difference found between the copolymerization constants r_1 and r_2 indicates that the copolymers must vary greatly in composition during the course of the process. In this case the calculation of integral and differential composition diagrams makes it possible to select conditions (original proportions of components, degree of conversion) under which copolymers may be prepared that are more uniform in composition.

HYDROGEN BONDING IN 6-CAPROLACTAM AND POLYCAPROLACTAM

V. N. Nikitin

One of the commonly used methods of studying hydrogen bonding is that of infrared spectroscopy. In a substance that is associated as a result of hydrogen bonding, the OH or NH vibrations are represented by a broad displaced band, which often has an unsymmetrical complex contour with several maxima. The question arises of the physical cause of the appearance of such a contour in the absorption band. Existing concepts [1, 2, 3] are able in some measure to explain the complex character of this band. Some authors ascribe the observed maxima in the band to different types of inter- and intra-molecular hydrogen bonds. For example, Shigorin, Mikhailov, and Makaryeva [4, 5, 6], who investigated synthetic polyamides, ascribed the three observed NH-group maxima to three types of hydrogen bonds. We consider that in several cases such an approach does not reflect the essential character of the phenomenon, since one type of bond may correspond to several maxima.

EXPERIMENTAL

The present paper is devoted to an investigation of the infrared spectrum of 6-caprolactam(2-oxohexamethylenimine)  and polycaprolactam $[-NH_3(CH_2)_5CO-]_x$ in the region 2400-3400 cm^{-1}.

A solution of 6-caprolactam in carbon tetrachloride was investigated in a cell 5.5 mm in thickness having rock-salt windows. Samples of 6-caprolactam were prepared by melting the substance between two rock-salt plates. The sample was placed in a special vessel such that the absorption spectrum could be investigated both at low and high temperatures. Deuterated 6-caprolactam was also investigated, this being prepared by the action of heavy water on 6-caprolactam for 24 hours with subsequent drying over phosphoric oxide. In the NH-vibration region, 6-caprolactam in carbon tetrachloride solution has clearly marked maxima at 3400, 3280, 3220, and 3080 cm^{-1}, with a suggestion of a band at 3160 cm^{-1}. On the basis of the results on deuterated and nondeuterated 6-caprolactam in carbon tetrachloride we showed that the maxima at 3280, 3220 and 3080 cm^{-1} characterize N–H vibrations in a hydrogen-bonded group. The results are given in Tables 1 and 2 and in Fig. 1.

As will be seen, in deuterated 6-caprolactam weak maxima in the region 3400-3080 cm^{-1} are preserved and new maxima, characteristic of N–D vibrations, appear at 2520, 2460, and 2400 cm^{-1} (Fig. 1). The absorption in the 3400-3080 cm^{-1} region is associated with the presence of nondeuterated substance in solution, for which there are two possible causes: 1) the replacement of hydrogen by deuterium did not proceed to completion; 2) the deuteration process went to completion, but residual water in the carbon tetrachloride reacted with the deuterium. Measurements of the transmission of the deuterated substance showed that, with passage of time, the transmission at 3400, 3280, and 3080 cm^{-1} diminishes and that at 2520, 2460, and 2400 cm^{-1} increases. The transmission of the CH bands remains unchanged. The change in transmission with time is associated with the replacement of deuterium in 6-caprolactam by hydrogen derived from water present in the carbon tetrachloride. This process is quite complete in 24 hours (Fig. 1). This result enables us to consider that the absorption at 3400, 3280, 3220, and 3080 cm^{-1} characterizes the NH group.

It was shown by the following experiment that the maxima 3280, 3220, and 3080 cm^{-1} had been correctly assigned to the vibrations of hydrogen-bonded NH groups. The optical densities of these maxima were determined for different concentrations of 6-caprolactam in carbon tetrachloride. If a measured band were not attributable to associated groups, then for a concentration ratio of 2 the ratio of optical densities D_{c_1} / D_{c_2} would also be 2, and any departure from this value would indicate that the band is actually to be attributed to associated groups. As will be seen from Table 2, the density ratios for the maxima at 3280, 3220, and 3080 cm^{-1} are not equal to 2, whereas for the CH band at 2970 cm^{-1} the ratio is very close to 2. Hence, the first three maxima characterize the linkage N–H···O.

The sharp band at 3400 cm^{-1} which is observed only in the solution of 6-caprolactam in carbon tetrachloride, must be assigned not to an intermolecular hydrogen bond as it was previously [4], but to the vibrations of a free NH

Fig. 1. Spectra 1 deuterated 6-caprolactam in CCl_4 (c = 2.84 mg/ml), and 2 the same after 24 hours.

A comparison of the absorption spectra of polycaprolactam and 6-caprolactam (Fig. 2) shows that the positions of the maxima are the same for these substances, but their intensities differ. As is known, the absorption at 3210 cm^{-1} in polycaprolactam [6] has been ascribed to an intramolecular hydrogen bond. This maximum however, exists also in 6-caprolactam, for which an intramolecular bond is excluded. Hydrogen bonds of two types are possible – in 6-caprolactam "twinning" and "catenating". We have shown, however, that there are three maxima characterizing the hydrogen bond. This example confirms the view that we expressed above, namely that it is impossible to attribute the maxima to bonds of different types. This view is confirmed also by the results of other workers [7], who observed two maxima at 3200 and 3090 cm^{-1} in a substance having only a "twinning" hydrogen bond. A particularly convincing example is provided by the absorption spectrum of 2,5-piperazinedione [8]. It was established both by X-ray [9] and by electron diffraction methods [10] that this substance contains only a "twinning" bond.

Fig. 2. Spectra of - 1 6-caprolactam at 70°; 2 6-caprolactam at 20°; 3 6-caprolactam at 150°; 4 a solution of 6-caprolactam in CCl_4 (c= 2.84 mg / ml); 5 polycaprolactam at 20°.

If it is considered that for each type of bonds there is a corresponding maximum, then in this case we should observe only one band. Experiment shows, however, that 2,5-piperazinedione gives six approximately identical maxima distributed in the region 2800-3400 cm^{-1} and corresponding to the linkage N—H···O [8]. Hence, the spectrum of 2,5-piperazinedione provides no basis for the assignment of the maximum at 3080 cm^{-1} in polycaprolactam to a "twinning" hydrogen bond, as has been done previously [6]. Shigorin and others [4, 5, 3] have investigated the variation of the intensity of the NH band in preparations of polycaprolactam varying in degree of crystallinity. They investigated also the dependence of the intensity of this band on the temperature [5]. It should be noted that the method selected for the evaluation of the intensities was a crude one and could give erroneous results if the specimens being compared were to vary in thickness. Having made this rough evaluation of the intensity, these workers concluded that in polycaprolactam, depending on the conditions of its formation, different types of hydrogen bonds were formed in different proportions. In our view the results can be interpreted otherwise, since the differences in the intensities of the NH bands of specimens differing in crystallinity can be related to differences in the proportion of amorphous material, an increase of which will lead to an increase in the mean distance between nitgrogen and oxygen atoms in N—H ···O linkages. We proposed a similar interpretation [11] in explanation of the differences between the spectra of crystalline sugar and candy. The effect of the amorphous region on the hydrogen-bond spectrum has been observed also in cellulose [12].

The variation of the intensity of the NH··· band with temperature is also incapable of being explained unequivocally on the basis of transitions from one type of bonding to another [5], since these changes can have another cause, associated with change in the population of the vibrational levels of the hydrogen bond [3]. In order to verify this view we investigated the spectra of 6-caprolactam and polycaprolactam at various temperatures. At —150° the 6-caprolactam band at 3080 cm^{-1} divides into two: 3075 and 3060 cm^{-1} (Table 1 and Fig. 2). We have observed similar phenomenon in certain organic crystalls [11]. In the 6-caprolactam melt there is a great change in the contour of the NH···band. In crystalline 6-caprolactam and in polycaprolactam hydrogen bonds are not broken in the transition from + 20° to - 150° — there is no transition of one type of bond into another, although the intensity of the NH··· vibrations and the position of the maxima vary. Thus, as the temperature is lowered the transmission of these substances at 3200 and 3080 cm^{-1} is reduced, though the transmission for the CH vibrations remains constant (Table 1). Fig. 3 gives the absorption spectrum of polycaprolactam at 20°, 150° and 220°. As the curves show, the transmission increases with rise of temperature at all of the maxima ~ 3280, 3200, and 3070 cm^{-1}. If these maxima characterized different types of hydrogen bonds [4, 5, 6] and rise of temperature brought about a transition from one type of bond to another [5], then at one maximum the transmission should increase, and at another diminish. Experiment shows that such behavior is not observed (Fig. 3).

Our results show that in the present case the variation in the intensities of the maxima with change in temperature is not associated with the transition of one type of bonds into another. Such a transition is possible in principle, but no light is thrown on such transitions by the observed temperature dependence of the differential intensity, since this dependence is characteristic of one type of bonds, the behavior being explicable on Stepanov's theory [3].

Fig. 3. Spectra of polycaprolactam: 1 - at 20°; 2 - at 150°; 3 - at 220°.

SUMMARY

1. It was shown that the maxima at 3280, 3220, and 3080 cm^{-1} observed in the absorption spectrum of 6-caprolactam characterize the vibrations of hydrogen-bonded NH groups. The band 3400 cm^{-1} given by 6-caprolactam in carbon tetrachloride solution is to be attributed to free NH groups.

2. The effect of temperature on the intensities and positions of the maxima characterizing the hydrogen bond in 6-caprolactam and polycaprolactam was investigated.

3. It was shown that the conclusions reached by some workers [4, 5, 6] regarding the existence of hydrogen bonds of three types in polycaprolactam must be regarded as doubtful.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 87. MIXED POLYAMIDES CONTAINING CERTAIN AMINO-ACID RESIDUES

V. V. Korshak and T. M. Frunze

In one of our previous communications we described mixed polyamides prepared by the reaction of ε-caprolactam (2-oxohexamethylenimine) with 1,6-hexanediamine salts of dicarboxylic acids. In this investigation we used the 1,6-hexanediamine salts of adipic, azelaic, and sebacic acids [1]. It was found that the melting points of the binary systems investigated passed through a minimum corresponding to an initial mixture containing 80 mole-% of ε-caprolactam and 20 mole-% of the 1,6-hexanediamine dicarboxylate. On the other hand, binary systems that we had investigated previously, which were derived from 1,6-hexanediamine salts of dicarboxylic acids, showed a minimum melting point for the product derived from 60 mole-% of the salt of the dicarboxylic acid having the larger number of methylene groups [2].

We have examined also the mechanism of the formation of mixed polyamides from a system containing ε-caprolactam and a diamine salt of a dicarboxylic acid, and we have shown that, depending on the proportions of the reactants and the progress of the reaction, there occur simultaneously both polymerization and polycondensation reactions; moreover, in the last stages of reaction the polymerization process no longer plays a significant role, the polyamide macromolecule being formed mainly as a result of polycondensational reactions [1].

It was of interest to determine the extent to which the regularities observed in binary systems containing ε-caprolactam retain their validity in systems containing other amino acids. With this object we have investigated systems containing 7-aminoheptanoic, 9-aminononanoic, or 11-aminoundecanoic acid as one of the original components of the reaction mixture. The second component of the system was a 1,6-hexanediamine salt of a dicarboxylic acid, namely, adipic, azelaic, or sebacic. Also, in the case of 7-aminoheptanoic acid, binary systems consisting of two amino acids were investigated, the reactants being ε-caprolactam and 7-aminoheptanoic acid.

EXPERIMENTAL

The experimental procedure and the investigation of the properties was carried out as described previously [2].

Starting Materials.

The starting materials had the following constants: 7-aminoheptanoic acid m.p. 187-188° (the literature [3] gives 183°); 9-aminononanoic acid m.p. 189-190° (the literature [4] gives 190°); 11-aminoundecanoic acid m.p. 185-186° (the literature [5] gives 186-187°). The remaining substances used had the constants given previously [1].

Results

The mixed polyamides obtained by the polycondensation of the substances indicated above, i.e., having an ω-amino carboxylic acid as one component, are white opaque horny substances. When drawn out in the molten state they readily form fibers capable of being cold-drawn. They are readily soluble in phenol, cresol, strong mineral acids, formic acid, and ethanol. Their solubilities vary over a wide range according to the relative amounts of the original components. In each system the products having the lowest melting point have the highest solubility. The dependence of the melting points of these products on the relative amounts of the components is shown in the table.

DISCUSSION OF RESULTS

As can be seen from the tabular data, the melting points of systems in which one of the original reactants is an amino acid vary with composition and pass through a minimum value. The position of the minimum is not constant, but varies according to the identities of the reactants; it corresponds to a mole fraction of 0.6-0.8 of the ω-amino carboxylic acid. The general character of the variation of the melting points is approximately the same

HS / Au	210–212	200–205	180–183	150–159	139–146	145–148	–	183–185

• The ratio of reactants is given in mole fractions. The numerator and denominator refer respectively to the substances indicated as numerator and denominator in the column headed "Names of reactants".

•• Abbreviations: Ad-adipic acid; Az- azelaic acid; S- sebacic acid- H- 1,6;hexanediamine; Ah - 7;aminoheptanoic acid- An - 9;aminononanoic acid- Au - 11-aminoundecanoic acid; C - 6-capcolactam.

as in the case of the previously described binary systems containing ε-caprolactam [1], as can be readily seen from the curves for the variation of the melting points of the systems investigated with variation in composition.

Fig. 1. Dependence of the melting points of polyamides containing 7-aminoheptanoic acid on composition: 1 - the system HAd-Ah; 2 - the system HAz-Ah; 3 - the system HS-Ah; 4 - the system C-Ah

In the case of systems derived from 7-aminoheptanoic acid and 1,6-hexanediamine salts of dicarboxylic acids (Fig. 1), it may be noted that in the system HS-Ah the lowest melting point corresponds to the product derived from a mixture containing a mole fraction of 7-aminoheptanoic acid of 0.6 (Fig. 1, Curve 3). The minimum for the system HAd-Ah also corresponds to a mole fraction of 7-aminoheptanoic acid of 0.6 (Fig. 1, Curve 1). On the other hand, the system based on the "odd" azelaic acid has a minimum at a mole fraction of 7-aminoheptanoic acid of 0.4 (Fig. 1, Curve 2), approaching the system C-Ah (Fig. 1, Curve 4) in this respect.

In the case of systems derived from 9-aminononanoic acid and diamine dicarboxylates, the system HAz-An (Fig. 2, Curve 2) has the lowest melting points in the systems containing HAd and HS correspond to a mole fraction of 9-aminononanoic acid of 0.7 (Fig. 2, Curves 1 and 3), and in the system containing HAz the minimum is at a mole fraction of 9-aminononanoic acid of 0.6 (Fig. 2, Curve 2). The system C-An differs in that the minimum is at a mole fraction of 9-aminononanoic acid of 0.4 (Fig. 2, Curve 4).

Fig. 2. Dependence of the melting points of polyamides containing 9-aminononanoic acid on composition: 1 - the system HAd-An; 2 the system HAz-An; 3 - the system HS-An; 4 - the system C-An

Fig. 3. Dependence of the melting points of polyamides containing 11-aminoundecanoic acid on composition: 1 - the system HAd-Au; 2 - the system HAz-Au; 3 - the system HS-Au.

In the case of systems containing 11-aminoundecanoic acid, the lowest melting point is found in the system HAz-Au (Fig. 3, Curve 2). In the HAd system the minimum corresponds to a mole fraction of 11-aminoundecanoic acid of 0.8 (Fig. 3, Curve 1). In the systems HAz-Au and HS-Au the minima correspond to a mole fraction of 11-aminoundecanoic acid of 0.7 (Fig. 3, Curves 2 and 3).

It may be noted, as a general tendency, that the melting points fall as the numbers of methylene groups in the chains of the reactants increase. For example, melting points in the systems containing 7-aminoheptanoic acid lie above those in the systems derived from 9-aminononanoic acid. Systems derived from 11-aminoundecanoic acid have still lower melting points. This kind of dependence has already been noted by us when examining the relationship between properties and structure in polyamides [6].

In conclusion we acknowledge our indebtedness to R. Kh. Freidlina and L. I. Zakharkin for placing samples of amino acids at our disposal.

SUMMARY

An investigation was made of binary systems of mixed polyamides prepared from an ω-amino acid (7-aminoheptanoic, 9-aminononanoic, or 11-aminoundecanoic acid) and 1,6-hexanediamine adipate, azelaate, or sebacate.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 58. POLYAMIDES CONTAINING ETHER LINKAGES IN THEIR MACROMOLECULAR CHAINS

V. V. Korshak and G. N. Chelnokova

Polyamides containing ether linkages in their macromolecular chains form a class of compounds that has received very little study. There are a few data on polyamides of this type in the scientific literature. Thus Hill [1] refers to a polyamide prepared from 1,5-pentanediamine and diglycolic acid. References to the preparation of polyamides from dicarboxylic acids and diamines containing ether linkages are given in various patents, which have been reviewed in articles by Somers [2].

Since polyamides containing ether linkages in their macromolecular chains are of interest not only as new members of a class of polyamides, but also because of their theoretical significance for the study of the relationship between the structure of a polymer and its properties, we undertook the preparation of several compounds of this type. The introduction of an ether linkage into the repeating unit of a polyamide macromolecule should increase the flexibility of the macromolecule and bring about changes in the properties of the polymer in the direction of increased solubility and hydrophilic character. It was of interest also to determine how the effect of the ether linkage depends on whether it is in the diamine residue or the dicarboxylic acid residue. We therefore used both reactants containing the ether oxygen in the diamine and also reactants containing the ether oxygen in the dicarboxylic acid. Also, in addition to single-component polyamides, i.e. those prepared from one diamine and one dicarboxylic acid, we prepared also mixed polyamides, i.e. copolymers obtained by the reaction of several components.

We prepared polyamides from the salts formed by 3,3'-(ethylenedioxy)-bispropylamine (ethylene glycol bis-3-aminopropyl ether) with adipic, azelaic, sebacic, and terephthalic acids, and also from the salt formed by 1,6-hexanediamine with diglycolic acid. We also carried out the polycondensation of systems of two components taken in various proportions. Two systems were investigated . 6-caprolactam with 3,3'-(ethylenedioxy)bispropylamine adipate, and 1,6-hexanediamine adipate with 3,3'-(ethylenedioxy)bispropylamine adipate.

The procedure used for the polycondensation was the same as that used previously [3]. Determinations were made of the melting points of the polyamides and of their solubilities in various solvents. The results are given in Table 1.

The polyamides obtained are flexible solids, soluble in cresol and in hydrochloric acid. Apart from the polyamide prepared from terephthalic acid, they all dissolve when heated with ethanol or 2-methoxyethanol, but the dissolved polyamide is almost entirely reprecipitated when the solutions cool. The same polyamides are slightly soluble in hot water.

The introduction of an oxygen atom into the polyamide chain results in a considerable lowering of melting point, as compared with the melting point of a polyamide in which the chain oxygen is absent but the total number of atoms in the chain is the same. For example, the polyamide prepared from glutaric acid and 1,6-hexanediamine melts at 220°, i. e. 145° higher than the polyamide prepared from diglycolic acid and 1,6-hexanediamine. In the same way, the polyamide derived from 1,10-decanediamine and adipic acid melts at 230°, whereas the polyamide derived from 3,3'-(ethylenedioxy)bispropylamine and adipic acid melts at 175-180°, i.e. 55° lower. The polyamide derived from 1,10-decanediamine and sebacic acid melts at 194°, and the polyamide derived from 3,3'-(ethylenedioxy)bispropylamine and sebacic acid melts at 157-160°, i.e. 37° lower. It is very obvious that the effect of the ether oxygen differs according to whether it forms part of the dicarboxylic acid or of the diamine. For example, the polyamide derived from diglycolic acid and 1,6-hexanediamine melts at a much lower temperature than the polyamide derived from adipic acid and 3,3'-(ethylenedioxy)bispropylamine in spite of the fact that the repeating unit of the latter is longer and contains two oxygen atoms, not one as in diglycolic acid. For the polyesters investigated by one of us in collaboration with Vinogradova [4], we showed that the introduction of each new oxygen atom

results in a proportionate lowering of the melting point of the polymer. In just the same way the lengthening of the repeating unit of the macromolecule by the introduction of methylene groups results in a lowering of the melting point, as can be readily seen even for the polyamides studied in this investigation. For example, the melting point of the polyamide derived from sebacic acid and 3,3'-(ethylenedioxy)bispropylamine is 13° lower than that of the polyamide derived from adipic acid and 3,3'-(ethylenedioxy)bispropylamine, which has a shorter repeating unit (by four methylene groups).

TABLE 1

Properties of Polyamides

Reactants		Properties of products			
Dicarboxylic acid	Diamine	M.p. (°C)*	Viscosity of 0.5% solution in cresol	Appearance	Solubility
Diglycolic	1,6-Hexanediamine	75–78	0.57	Solid	Dissolves in cresol and in hydrochloric acid. Soluble hot in alcohol; reprecipitated almost completely when solution cooled.
Adipic	3,3'-(ethylenedioxy)bispropylamine	175–180	0.40	Ditto	Dissolves in hot alcohol; reprecipitated completely when solution cooled. Slightly soluble in hot water.
Azelaic	Ditto	127–130	0.59	" "	Ditto
Sebacic	" "	157–160	0.75	" "	" "
Terephthalic	" "	236–240	0.57	" "	Dissolves in cresol and in hydrochloric acid

* These melting points were measured as follows: A piece of the polymer, approximately 3 mm x 3 mm x 1 mm, was placed in a test tube, and a layer of paraffin (about 10 mm) was introduced so as to cover completely the bulb of a thermometer placed in the tube. The test tube was placed in a glycerol bath, which was heated so that the temperature in the test tube rose at the rate of 1° per minute. The melting point was taken to be the range of temperature at the beginning of which the polymer began to be deformed (when pressed with the thermometer) and at the end of which the sample began to be capable of being drawn into a thread.

There is therefore an essential difference between the effect of an ether oxygen and a methylene group. As shown by one of us and Frunze [5], the melting point of a polyamide not containing ether linkages in the macromolecular chain depends on the ratio of the total number of methylene groups in the repeating unit to the number of amide groupings in the case of polyamides derived from dicarboxylic acids and diamines having even numbers of carbon atoms in their molecules; in the case of polyamides derived from dicarboxylic acids or diamines having odd numbers of carbon atoms in their molecules, the melting point depends on the ratio of the number of methylene groups to the number of hydrogen bonds. In these cases it is of no significance whether the methylene groups are in the dicarboxylic acid molecule or in the diamine molecule. As can be seen from the properties of the polyamides described in the present paper, there is a substantial difference between the properties of polyamides in which the ether linkage is in the dicarboxylic acid residue and those of polyamides in which the ether linkage is in the diamine residue. The ether linkage is considerably more effective when it is in the dicarboxylic acid molecule, for it brings about a greater melting point lowering than two ether linkages in the diamine molecule.

Apart from single-component polyamides, we prepared some mixed polyamides from ε-caprolactam (C) and 3,3'-(ethylenedioxy)bispropylamine adipate (EA), the ratio of reactants being varied from 1:0 to 0:1. The melting points of these mixed polyamides and the specific viscosities of their solutions are given in Table 2.

The products were almost colorless horny solids, the melts of which readily formed fibers that were capable of being cold drawn. As shown in Fig. 1, the melting points of the mixed polyamides pass through a minimum.

0	100	175–180	0.40

We also investigated the system HA-EA (HA = 1,6-hexanediamine adipate). The melting points of these mixed polyamides and the specific viscosities of their cresol solutions are given in Table 3 and Fig. 2.

EXPERIMENTAL

Diglycolic Acid. Diglycolic acid was prepared from chloroacetic acid by heating it with baryta water [6]. Yield 71%; m.p. 143.5-144° (from water).

1,6-Hexanediamine Diglycolate. A solution of 19.2 (10% excess) of 1,6-hexanediamine in 5 ml of 80% ethanol was added to a solution of 20 g of diglycolic acid in 70 ml of 80% ethanol. The solution was filtered through a sintered glass filter and then set aside. The crystals that formed were filtered off and washed on the filter with

ethanol; m.p. 165-166°; yield 70%.

3,3'-(Ethylenedioxy)bispropylamine Terephthalate. A mixture of 26 g (0.148 mole) of 3,3'-(ethylenedioxy)-bispropylamine, 31 g (0.187 mole) of terephthalic acid, and 200 ml of ethanol was refluxed in a round-bottomed flask in a water bath for about 40 minutes. Water (20 ml) was added to the hot solution in order to dissolve the salt, and the mixture was filtered hot from undissolved terephthalic acid. The residue was boiled for ten minutes with a little water, and the solution obtained by filtration was added to the main filtrate. The solution was cooled and the salt was precipitated by addition of an equal volume of acetone. Two recrystallizations from ethanol gave crystals melting at 208-209°. Yield 40%.

3,3'-(Ethylenedioxy)bispropylamine Adipate. Adipic acid (8.3 g) was warmed with 20 ml of ethanol, and 10 g of 3,3'-(ethylenedioxy)bispropylamine was added gradually to the resulting solution. After being cooled and allowed to stand, the solution yielded crystals of the salt, which were filtered off, recrystallized from alcohol, and dried in the air; m.p. 119-120°; yield 66%.

3,3'-(Ethylenedioxy)bispropylamine Azelaate. This salt was prepared like the adipate; m.p. 114-116°.

3,3'-(Ethylenedioxy)bispropylamine Sebacate. This salt was prepared like the adipate; m.p. 147-148°.

In conclusion we gratefully acknowledge our indebtedness to I. N. Nazarov, who kindly placed some 3,3'-(ethylenedioxy)bispropylamine at our disposal.

SUMMARY

1. A polyamide was prepared from diglycolic acid and 1,6-hexanediamine.

2. Polyamides were prepared from 3,3'-(ethylenedioxy)bispropylamine and dicarboxylic acids, namely, adipic, azelaic, and sebacic.

3. Mixed polyamides were prepared from ε-caprolactam and 3,3'-(ethylenedioxy)bispropylamine adipate and from 1,6-hexanediamine adipate and 3,3'-(ethylenedioxy)bispropylamine adipate, the reactants being taken in various proportions.

4. It was shown that the introduction of an ether oxygen into the repeating unit of a polyamide macromolecule results in a lower melting point and a higher solubility, as compared with a polyamide having the same length of repeating unit, but not containing ether linkages.

5. It was found that an ether oxygen in the dicarboxylic acid residue brings about a much greater lowering of the melting point of the polyamide than an ether oxygen in the diamine residue.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 89. THREE-COMPONENT MIXED POLYAMIDE SYSTEMS HAVING AMINO-ACID COMPONENTS

V. V. Korshak, T. M. Frunze, and T. A. Dikareva

In a previous communication we described three-component mixed polyamide systems prepared from the components 1,6-hexanediamine adipate (HAd), 1,6-hexanediamine sebacate (HS), 1,6-hexanediamine azelaate (HAz), and 6-caprolactam (C) in the combinations HAd-HAz-HS, HAd-HS-C, HAd-HAz-C, and HS-HAz-C [1]. Investigation of the properties of these copolymers showed that as the content of each of the components was increased, the properties changed. There was a lowering of melting point and an increase in solubility. The lowest melting points and highest solubilities were found for products having compositions lying in the central part of the composition diagram.

The object of the present investigation was the study of systems containing, as one component, 7-aminoheptanoic (Ah), 9-aminononanoic (An), or 11-aminoundecanoic (Au) acid. The second and third components were selected from HAd, HS, HAz, and C, taken in various combinations. The procedure used for the polycondensation and for the investigation of the products were the same as those used previously, and the constants of the starting materials are also given in preceding communications [1-3].

EXPERIMENTAL

We investigated the following three-component systems: HAd-HAz-Ah, HAd-HS-Ah, HS-HAz-Ah, HAd-C-Ah, HS-C-Ah, HAd-C-An, HS-HAz-Au, and HAd-C-Au. We also prepared polycondensation products for the systems HAd-HAz-An, HS-HAz-An, and HAd-HAz-Au. In the last three systems we did not prepare and investigate products corresponding to all of the points on the composition diagrams, but prepared only a few products corresponding to the central part of the diagram, which were taken as being the most typical and providing a general idea of the properties of members of these three-component systems. The compositions and melting points of products derived from 7-aminoheptanoic acid are given in Table 1.

The melting points of products derived from 9-aminononanoic and 11-aminoundecanoic acids are given in Table 2.

The polyamides obtained are opaque horny solids. In the molten state they are readily drawn into threads, which are capable of being cold-drawn. The products are readily soluble in phenol, cresol, formic acid, and strong mineral acids. Some of them are soluble in ethanol.

DISCUSSION OF RESULTS

The dependence of melting point on composition is shown for the systems investigated in Figures 1-8. The general character of the dependence is similar to that found in the systems investigated previously. The lowest melting points are usually found for products having the most "central" composition. It is interesting to note that, as in systems investigated previously, there is a displacement of the regions bounded by isotherms in the direction of "odd" and longer components; this can be seen from the diagrams.

In the case of systems containing 7-aminoheptanoic acid and diamine dicarboxylates, it is noteworthy that the lowest melting point is found in the system HAd-HS-Ah (Fig. 1). It is found for compositions lying in the central part of the diagram. The region of compositions bounded by the 170° isotherm differs in form in the three diagrams (Figures 1, 2, and 3). In the system HAd-HS-Ah (Fig. 1) it is displaced in the direction of the longest component, i.e. sebacic acid. In the system HAd-HAz-Ah (Fig. 2) it is displaced in the direction of adipic acid, which is somewhat anomalous in relation to previous observations. In the system HS-HAz-Ah (Fig. 3) this region is displaced in the direction of the longest component, which is in accord with previous observations.

Systems containing ε-caprolactam in addition to 7-aminoheptanoic acid differ greatly from the preceding systems. Products corresponding to central compositions in these systems have lower melting points. Of the two systems of this type that we have investigated, HS-C-Ah (Fig. 5) has the lower minimum melting point (125°), and the 150° isotherm surrounds a larger area than in the system HAd-C-Ah (Fig. 4). In the latter system the product of lowest melting point melts at 135°; the area bounded by the 150° isotherm and by the 175° isotherm are very much smaller than in the system HS-C-Ah. In the system HAd-C-An (Fig. 6) the region of products bounded by the 150° isotherm is displaced in the direction of the amino acids; the region of products bounded by the 170° isotherm occupies a considerable fraction of the diagram.

	35–35–30	35–35–30	25–50–25	25–50–25

• 1. Abbreviations: HAd 1,6-hexanediamine adipate; HAz 1,6-hexanediamine azelaate; HS 1,6-hexanediamine sebacate; C ε-caprolactam; Ah 7-aminoheptanoic acid.

2. The denominator gives the percentages by weight of the reactants in the order shown at the head of the columns. The numerator gives the melting point of the product (°C).

In the system HAd-C-Au (Fig. 7) the region of products bounded by the 150° isotherm is again displaced in the direction of the amino acids; the region bounded by the 170° isotherm is again very great. In the system HS-HAz-Au (Fig. 8) a somewhat different picture is found: the region of products bounded by the 150° isotherm is displaced toward 11-aminoundecanoic acid and is somewhat deformed in the direction of azelaic acid.

The lowest melting points found in the investigated systems (125-126°) are those of products lying in the central parts of the systems HS-C-Ah, HAd-C-Au, and HS-HAz-Au. When we compare analogous systems differing only in the amino acid, e.g. HS-HAz-Ah, HS-HAz-An, and HS-HAz-Au, it is found that with increase in the chain length of the amino acid the melting point falls for a given composition. The same applies to the system HAd-HS-Ah, HAd-HS-An, and HAd-HS-Au.

In conclusion we acknowledge our indebtedness to R. Kh. Freidlina and L. I. Zakharkin for kindly placing the amino acids at our disposal.

SUMMARY

1. An investigation was made of systems of mixed polyamides prepared from three components selected from 7-aminoheptanoic, 9-aminononanoic, and 11-aminoundecanoic acids, 1,6-hexanediamine adipate, azelaate, and sebacate, and 6-caprolactam.

2. It was found that the lowest melting points and highest solubilities were possessed by products lying in the central part of the composition diagram.

3. It was found that the regions bounded by isotherms were displaced in the direction of " odd " components and also in the direction of components having the longest molecules.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 90. POLYCONDENSATION OF 1,2-DICHLOROETHANE WITH TETRALIN

G. S. Kolesnikov, V. V. Korshak, M. A. Andreeva, and A. I. Kitaigorodsky

It was shown in a previous paper [1] that, when the catalyst concentration is low, the polycondensation of 1,2-dichloroethane with o-dichlorobenzene proceeds like that of bifunctional compounds, in spite of the fact that the potential functionality of o-dichlorobenzene is four. As we wished to determine whether the behavior found in the polycondensation of 1,2-dichloroethane with o-dichlorobenzene is general for disubstituted benzenes— which have a potential functionality of four in alkylation reactions in presence of aluminum chloride — we undertook a study of the polycondensation of 1,2-dichloroethane with tetralin (1,2,3,4-tetrahydronaphthalene). Tetralin may be regarded as an o-dialkylbenzene.

Polycondensation of 1,2-dichloroethane with tetralin; M-molecular weight; A-molar ratio dichloroethane: tetraline; B-molar ratio tetralin: dichloroethane.

In order to determine the effect of the relative amounts of the reactants on the yield and molecular weight of the polymer [poly(ar-ethylenetetralyl)], we carried out a series of experiments in which the amounts of tetralin and aluminum chloride were kept constant, but the amount of dichloroethane was varied over a wide range; the temperature and duration of the reaction were also kept constant. The amount of aluminum chloride was 10 mole% on the amount of tetralin. The procedure used for the polycondensation was the same as that used previously [2, 3], with the exception that dilution of the polycondensation products after decomposition with dilute hydrochloric acid was effected not with benzene, but with dichloroethane. The dichloroethane was distilled from the solution of polycondensation products, and further distillation under reduced pressure removed tetralin and 1,2-di-2-tetralylethane [1,2-bis(5,6,7,8-tetrahydro-2-naphthyl)ethane] which came off at 150-230° (1-2 mm). The residue was not treated further. For the purpose of molecular weight determinations, a small amount of the polymer was reprecipitated from benzene solution with methanol. The results of the experiments are given in Table 1 and in the figure. The poly(ar-ethylenetetralyl) so obtained was a brittle solid.

It will be seen from Table 1 and the figure that with reduction in the tetralin : dichloroethane ratio the molecular weight of the poly(ar-ethylenetetralyl) rises, attaining a maximum at a ratio of 1.10. Unlike the polycondensation of 1,2-dichloroethane with o-dichlorobenzene [1], reaction of equimolecular amounts of 1,2-dichloroethane and tetralin does not give a polymer of maximum molecular weight. This result is not fortuitous, for repeat experiments with equimolecular amounts of reactants gave a polymer having the same molecular weight within the limits of experimental error. Polycondensation with excess of dichloroethane resulted in a lowering of the molecular weight of the polymer to an extent that was the greater, the greater the excess of dichloroethane. In the polycondensation of 1,2-dichloroethane with tetralin, as also in the polycondensation of 1,2-dichloroethane with o-dichlorobenzene [1], the formation of three-dimensional polycondensation products was not observed even when there was a great excess of dichloroethane.

• Calculated on the amount of tetralin taken.

•• 27.3% of tetralin was recovered unchanged.

When the tetralin was in excess, the yield of macromolecular polycondensation products remained almost constant, independent of the relative amounts of the reactants. When the dichloroethane was in excess, the yield of poly(ar-ethyleneteralyl) fell as the ratio dichloroethane: tetralin increased. As will be seen from Table 1, as the excess of tetralin was reduced, the yield of 1,2-di-2-tetralylethane fell, reaching a minimum at a dichloroethane: tetralin ratio of 1.25; further increase of this ratio resulted in an increase in the yield of 1,2-di-2-tetralylethane. It is interesting that the maximum yield of symmetrical tetrachlorobibenzyl in the polycondensation of 1,2-dichloroethane with o-dichlorobenzene was obtained at a dichloroethane: o-dichlorobenzene ratio of 1.21 [1]. This lowering of the yield of 1,2-di-2-tetralylethane, like the lowering of the yield of symmetrical tetrachlorobibenzyl, is to be explained by the reduction of the concentration of the aromatic hydrocarbon in the reaction mixture. However, the increase in the yield of the initial polycondensation product with increase in the excess of dichloroethane is, in our opinion, to be explained by the lowering of the concentration of the catalyst and reaction complex as a result of dilution with dichloroethane, which leads to a reduction in the overall rate of the process and a retardation of the process in its early stages. This then is the cause of the reduction in the yield of polymer when there is a large excess of dichloroethane. The absence of halogen (Beilstein test) in the poly(ar-ethyleneteralyl) obtained with an excess (even 100% excess) of dichloroethane indicates that excess of dichloroethane does not degrade the polymer and no products containing the CH_2CH_2Cl group are formed.

It is unexpected that a polymer of maximum molecular weight should be formed at a tetralin: dichloroethane ratio of 1.10: 1 rather than 1: 1, as observed for the reactant ratio in the polycondensation of dichloroethane and o-dichlorobenzene. One possible cause is the contamination of the tetralin with decalin, but a refractive index determination on our tetralin showed that decalin was virtually absent; the value found for n_D^{20} was 1.5416, which is almost exactly the value for pure tetralin, namely 1.54135 [4] (the determination of the refractive index has been proposed as a method for the determination of decalin in tetralin [4]). Another possible cause of the anomaly is the participation of tetralin in side reactions with a resulting reduction of its concentration in the reaction mixture.

It is known [5, 6] that tetralin, heated with small amounts (1-4%) of aluminum chloride at 30-100°, can yield benzene, octahydroanthracene, octahydrobinaphthyl, and other aromatic and hydroaromatic compounds. There can be no doubt that such reactions could occur in the polycondensation of tetralin with dichloroethane in presence of aluminum chloride at about 100°, and they would lead to a reduction in the concentration of tetralin in the reaction mixture and to a shift in the position of the molecular weight maximum for poly(ar-ethylenetetralyl).

The low-molecular-weight product obtained in the polycondensation of 1,2-dichloroethane with tetralin in presence of aluminum chloride is 1,2-di-2-tetralylethane. In order to obtain it in the pure state the product boiling at 150-230° (1-2 mm) was redistilled under reduced pressure, the fraction boiling at 190-215° (2 mm) being collected. The distillate was then crystallized twice from a 4:1 mixture of alcohol and dichloroethane, the product being a substance melting at 99-100°. Further recrystallization did not raise the melting point. The results of analysis and determination of molecular weight were in good agreement with the calculated values.

Calculated M 290.4

The structure of this compound, which has not been described in the literature, was established as the result of X-ray diffraction measurements. 1,2-Di-2-tetralylethane crystals prepared by the slow evaporation of an acetone solution have the form of thin square plates, ranging up to 1 sq. cm in area. Goniometric measurements and the symmetry of the X-ray pattern indicated that the crystals belonged to the prismatic class of the monoclinic syngony C_{2h}. The b axis coincides with the one diagonal of the plate, and the c axis coincides with the other. The following simple forms exist: 1) pinacoid a (100); 2) prism n (111), and 3) prism m (011).

Results of Goniometric Measurements

Face	ρ	φ	Symbol
1	90°	0°	(100)
2	90°	180°

5	128°20'	128°37'	
6	128°20'	308°37'	
7	45°20'	101°15'	(011)
8	45°20'	281°15'	
9	134°40'	101°15'	
10	134°40'	281°10'	

The parameters of the elementary cell, determined from oscillation photographs and Fourier analysis, are:

a = 13.35 ± 0.08 A
b = 8.01 ± 0.05 A
c = 7.97 ± 0.05 A
β = 101.15 ± 0°30'

Space group $P2_1/c = C^5_{2h}$. The number of molecules in the elementary cell Z = 2, i. e. the molecules are at the centers of symmetry.

The results of the X-ray-structure analysis permit us to assert that the ditetralylethane obtained is a di-2-tetralyl compound. The number of molecules in the cell taken in conjunction with the symmetry of their mutual dispositions indicates that the molecule has a center of symmetry, so that a 1-tetralyl-2-tetralyl compound is excluded. The similarity of the section bc, which contains the centers of both cyclic groups, to the sections of 2,6- and 2-derivatives of naphthalene [7] enables us to reject the di-1-tetralyl compound, which cannot be arranged geometrically into a cell of the form found.

Attempts to establish the structure of poly(ar-ethylenetetralyl) by destructive oxidation with chromic acid were

unsuccessful, and we did not succeed in isolating any of the benzenetetracarboxylic acids whose formation could be expected. The product was a mixture of acids, and attempts to separate it were unsuccessful. On the basis of the structure of the low-molecular-weight product of the polycondensation and theoretical considerations concerning the orienting effects of substituents in the benzene ring it may be supposed that in poly(ar-ethylenetetralyl) the tetralin residues are linked together through $-CH_2CH_2-$ groupings at the two β-positions of the aromatic ring of the tetralin, i.e.

With this arrangement of $-CH_2CH_2-$ groupings, each of them will be in the meta position to one of the original substituents (a CH_2 of the hydroaromatic ring) and in the para position to the other; at the same time these groupings will be ortho to each other.

In order to determine the effect of the concentration of catalyst on the yields and molecular weights of products of the condensation of 1,2-dichloroethane with tetralin, a series of experiments were carried out in which the tetralin : dichloroethane ratio (1.5 : 1), the temperature (100°), and the duration of the experiment (4 hours) were kept constant, and the catalyst concentration was varied over a wide range. The results are given in Table 2.

It will be seen from Table 2 that at first an increase in catalyst concentration leads to an increase in the yield of poly(ar-ethylenetetralyl), but when a concentration of 9-1 % (on the tetralin) is reached the yield of macromolecular products becomes almost constant. Over the range of catalyst concentrations studied, the molecular weight of the poly(ar-ethylenetetralin) remains constant, i.e. is independent of the concentration of catalyst over the range 3-12 mole-% (on the tetralin).

TABLE 2

Polycondensation of 1,2-Dichloroethane with Tetralin (Tetralin : dichloroethane = 1.5 : 1)

Concentration of catalyst (mole-%)		Yield (%)		Concentration of benzene solution of poly(ar-ethylenetetralyl)	Specific viscosity of benzene solution	Molecular weight of poly(ar-ethylenetetralyl)
on the tetralin	on the dichloroethane	1,2-Di-2-Tetralylethane	Poly(ar-ethylenetetralyl)

10.0	15.0	9.4	81.2	3.048	0.095	2740
12.0	18.0	8.8	82.7	3.646	0.128	3080

In order to check whether the solutions used for the viscosimetric determination of the molecular weight of poly(ar-ethylenetetralyl) were too highly concentrated, times of efflux were determined for benzene solutions of one of the polymers, molecular weights being calculated from the results. The results of these measurements are given in Table 3.

It will be seen from Table 3 that the molecular weight determined by the viscosimetric method does not depend on the concentration of the poly(ar-ethylenetetralyl) solution over the range 1-10 g/100 ml. Within these limits, therefore, rise in concentration does not bring about association of poly(ar-ethylenetetralyl) molecules. The experimentally determined carbon and hydrogen contents of poly(ar-ethylenetetralyl) were in close accord with the values calculated for repeating the unit:

$C_{12}H_{14}$. Calculated %: C 91.14; H 8.86 Found %: C 91.18; 91.26; H 8.74; 8.68

SUMMARY

1. A study was made of the polycondensation of 1,2-dichloroethane with tetralin in presence of aluminum chloride, and the main features of the process were established.

2. On the basis of X-ray-structure analysis it was established that the product formed in the first stage of the polycondensation of 1,2-dichloroethane with tetralin is 1,2-di-2-tetralylethane [1,2-bis(5,6,7,8-tetrahydro-2-naphthyl)ethane].

3. It was found that no three-dimensional products are formed in the polycondensation of 1,2-dichloroethane with tetralin, in spite of the fact that the potential functionality of tetralin is four.

4. It was shown that the polymer [poly(ar-ethylenetetralyl)] does not undergo association in benzene solution at concentrations of up to 10 g per 100 ml.

INFRARED ABSORPTION SPECTRA OF SOME BASES OF THE PYRIDINE SERIES

D. N. Shigorin, Ya. L. Danyushevsky, and Ya. L. Goldfarb

Compounds of the type of α-aminopyridine (I) and N-alkyl-α-pyridonimine (II), which contains an amidine grouping are peculiar in that they can combine stably with only one proton in their salts. It was concluded in a previous study [1] of ultraviolet absorption spectra that in bases of the first type the salt-forming center is the ring nitrogen, whereas in bases of the second type it is the side-chain nitrogen.

(I)

R (II)

It was of interest to investigate the relative basicities of the nitrogen atoms in these systems with the aid of infrared absorption spectra in the region of the vibration frequencies of the NH_2 group, so that we could examine the changes occurring in just that part of the molecule that is attacked by the proton.

The basis of this method is the known fact that in its vibration spectrum the amino group differs from the $\overset{+}{N}H_3$ group, in which a quadrivalent nitrogen atom carries a positive charge [2]. When we pass from the group to the group or the deformed amino group , the N–H bands are displaced toward the longer waves. For example, in the infrared absorption spectrum of liquid aniline the group is characterized by three bands at 3440 (8), 3357 (10), and 3220 (5) cm^{-1}. In an inert solvent and in the vapor these bands are somewhat displaced toward the shorter waves owing to the breakdown of intermolecular association through hydrogen bonds. Under these conditions the frequencies of the $-NH_2$ group have the values 3490 (10), 3410 (10), and 3230 (10) cm^{-1}. The first and second bands correspond respectively to antisymmetrical and symmetrical vibrations of the hydrogen atom with respect to the nitrogen atom. The 3220 cm^{-1} band is probably an overtone of the deformational band of the NH_2 group, which has an enhanced intensity owing to Fermi resonance [3].

In the spectrum of aniline hydrochloride, which we measured for the crystalline state in the form of a paste* there is considerable displacement of the absorption bands toward the longer waves; the shortest band has a frequency of 3100 cm^{-1}. The considerable lowering of the frequencies of the N–H vibrations in the aniline hydrochloride crystal is probably to be explained by the change in the valency state of nitrogen atom and the strong ionic interaction. Apart from these bands the aniline hydrochloride spectrum contains also an intense diffuse band at a frequency of about 2575 cm^{-1}, which probably belongs to ···HCl. The spectrum of gaseous hydrogen chloride has a clearly defined rotational structure, and from this a frequency of about 2875 cm^{-1} can be derived [3, 4]. In aniline hydrochloride, therefore, the HCl band is very much displaced toward the long waves. This may be interpreted as follows: crystalline aniline hydrochloride is a stable molecular compound, and not an ionic compound . If a true salt of the ammonium chloride type were formed, then the HCl band, as such, would not be detected. The results cited can be applied to the explanation of the results of the study of the infrared spectra of bases of the α-aminopyridine and N-alkyl-α-pyridonimine series and their salts.

EXPERIMENTAL

The spectra were measured on a Soviet IKS-1 recording infrared spectrometer. Measurements in the 2.5–5.5

* Aniline hydrochloride was purified by sublimation.

μ region were carried out with LiF prism, and in the 5-10μ region with a rock salt prism. The frequencies were measured accurate within ± 5 cm^{-1}. The results of the measurements in the N−H region are given in Table 1.

TABLE 1 *

α-Aminopyridine. Three bands characterizing the NH_2 group, 3445, 3306, and 3170 cm^{-1}, were observed in the spectrum of crystalline α-aminopyridine. Its solutions in inert solvents e.g. benzene (1:20), gave two bands, 3490 (10) and 3395(8) cm^{-1} in place of the one high-frequency band 3445(10, diffuse) cm^{-1}. The 3306(5, diffuse) cm^{-1} band of crystalline α-aminopyridine preserved its value almost unchanged (3315(2) cm^{-1}). The 3170 cm^{-1} band was also preserved at high intensity, but when the inert solvent was replaced by dioxane or acetone it disappeared com-

* Continued on next page

pletely. It is probable that the interpretation of this fact is that the 3170 cm^{-1} band is due to an NH linkage participating in the formation of a dimer by hydrogen bonding:

TABLE 1 Continued

8	N-Benzyl-α-pyridonimine hydrochloride, crystal		3345(3), 3320(1), 3190(5), 3120(3)
9	α-Aminonicotine methiodide		3405(5), 3310(10), 3205(3)
10	α-Methylaminopyridine, liquid		3285(10, diffuse)
	Ditto + CCl_4 (1:20)		3270(10)

The association of α-aminopyridine molecules is experimentally confirmed by the results of molecular weight determinations in benzene solutions of this base at various concentrations. It will be seen from the results presented in Table 2 that the average molecular weight of α-aminopyridine rises regularly with increase in concentration.

In acetone or dioxane these dimers are broken down, and >N–H.....N< linkages are replaced by >N–H.....O, linkages, which are characterized by the frequencies 3362 and 3375 cm^{-1}, respectively, for dioxane and acetone solutions. The formation of dimers has been proved in various carboxylic acids [5], amidines [6, 7], and

other compounds. The 3445 cm^{-1} band in the spectrum of crystalline α-aminopyridine must probably be attributed to an N−H bond that takes part in weaker hydrogen bonds; the 3306 cm^{-1} corresponds to the overtone of the deformational NH_2 band, which is intensified as a result of Fermi resonance.

TABLE 2

Relative weights of α-aminopyridine and benzene	Molecular weight of α-aminopyridine (determined cryoscopically)	Relative weights of α-aminopyridine and benzene	Molecular weight of α-aminopyridine (determined cryoscopically)
1:28.0	139	1:70.0	122
1:28.3	142	1:75.6	117
1:39.0	130	1:83.0	116
1:40.5	129	1:96.5	110
1:42.5	128	1:108	110
1:50.5	126	1:149.4	111
1:52.0	125		

In dilute solutions of α-aminopyridine in nonpolar solvents (benzene, CCl_4), free NH_2 groups make their appearance with symmetrical and antisymmetrical vibrations. In particular, in carbon tetrachloride the relevant frequencies are 3500 (10) and 3410 (4) cm^{-1}, which scarcely differ from the corresponding frequencies for the NH_2 group of aniline in the same solvent [3490 (10) and 3410 (10) cm^{-1}]. Finally, the bands at 3315, 3225, and 3210 cm^{-1}, observed in solutions, probably characterize the overtone of an NH_2 group intensified by Fermi resonance.

N−Methyl-α-pyridonimine. In the NH region of the spectrum of liquid N-methyl-α-pyridonimine there is one band at 3335 (10) cm^{-1}, which characterizes the valency vibration of hydrogen with respect to the nitrogen atom in the NH group. This band does not alter in a dilute (1:50) solution in hexane, which indicates the presence of stable intermolecular hydrogen bonds. One of the authors has observed a similar phenomenon in an investigation of the vibration spectra of amidines [6, 7]. In the spectrum of a solution of M-methyl-α-pyridonimine in dioxane (1:10), a band was observed at 3300 cm^{-1}, which probably characterizes an = N−H group participating in the formation of more stable hydrogen bonds = N−H · · ·O.

In the double bond region the frequencies 1650 (5) and 1570 (3) cm^{-1} were observed. The more intense of these probably characterizes the C = N bond [2]. The frequency 1570 cm^{-1} is probably to be associated with the system of conjugated double bonds.

α-Aminopyridine Hydriodide. The spectrum of this compound in the NH region is characterized by four bands. In spite of the fact that they differ in frequency and intensity from the bands given by crystalline α-aminopyridine, it may be concluded that in the hydriodide of this base, as in the base itself, there is an NH_2 group and that, consequently, in salt formation the proton adds to the nitrogen atom of the ring. If in fact the proton added to the side-chain nitrogenatom with formation of the group, a considerable displacement of the bands toward

the long waves would have been observed—a displacement comparable to that observed in the comparison of the spectra of aniline and its salt (see above). The short-wave band of the hydriodide has a frequency of 3310 cm^{-1}, which differs from the short-wave band of the base by about 130 cm^{-1}, whereas in the case of aniline and its hydrochloride this difference is about 340 cm^{-1}.

The displacement of bands toward the longer waves which is observed when we compare α-aminopyridine with its hydriodide can be explained on the view that the amino group of the latter is deformed; it is probable that in such salts the positive charge is distributed between the two nitrogen atoms of the amidine grouping.

N-Methyl-α-pyridonimine Hydriodide. The spectrum of this salt contains four fairly intense bands, displaced with respect to the NH_2 bands of α-aminopyridine in the direction of the longer waves. The fact that four bands are formed already indicates that the proton unites with the side-chain nitrogen with formation of a salt of structure

I, containing a deformed NH_2 group.

If the salt-forming center were actually the ring nitrogen atom, then the salt  I, would be

formed, and the spectrum of this would contain one or two bands characterizing the vibrations of N—H bonds, and not four bands, as found by experiment. The data in Table 1 show that a monosubstituted aminopyridine, namely α-benzylaminopyridine, does in fact give a single absorption band in the crystalline state.

In view that N-methyl-α-pyridonimine hydriodide contains an NH_2 group is supported also by the resemblance of the spectrum of this salt to that of α-aminopyridine hydriodide. As indicated above, the bands of this group are displaced toward the longer waves; an explanation of this fact can be given on the basis of the same considerations as those given in the description of the spectrum of α-aminopyridine hydriodide (see above).

N-Benzyl-α-pyridonimine Hydrochloride. In the region of the N—H frequencies, the spectrum of this compound is similar to that of N-methyl-α-pyridonimine hydriodide. There are four bands characterizing a deformed NH_2 group: 3345 (3), 3320 (1), 3190 (5), and 3120 (3) cm^{-1}. In this case also, therefore, confirmation is found for the conclusion that the salt-forming center in systems of the type of N-alkyl-α-pyridonimine is the side-chain nitrogen atom.

α-Aminonicotine Methiodide. A study of the reactions of one of the products of the reaction of α-aminonicotine with methyl iodide showed that of the two possible structures a and b, it is necessary to assign it the structure a [8].

a

b

It was of interest to determine how far this result is in accord with the absorption of the compound in the infrared region. The data in Table 1 show that the spectrum of this compound contains three bands characterizing the N—H bonds: 3405 (5), 3310 (10), and 3205 (3) cm^{-1}. The spectra of α-aminopyridine and N-methyl-α-pyridonimine hydriodides, which have structures similar to formula b, differ from that of this methiodide; this could be explained by the deformation of the amino group in the two hydriodides. On the other hand, when the spectra of the methiodide is compared with that of crystalline α-aminopyridine, in which the amino group is free from the influence of the quadrivalent ring nitrogen atom, a close resemblance is observed, which is in full accord with structure a. In Table 1, apart from the data considered above, the frequency is given for N-methylaminopyridine, a compound isomeric with N-methyl-α-pyridonimine.

SUMMARY

1. Comparison of the infrared absorption spectra of compounds of the α-aminopyridine and α-pyridonimine series shows that the more basic nitrogen atom in these compounds is that bound by a double bond; this nitrogen atom functions as a salt-forming center.

2. It is established that in α-pyridonimine derivatives addition of a proton at the side-chain (imine) nitrogen atom results in a redistribution of electron density with formation of a molecule of "benzenoid" structure. In salts of bases of the α-aminopyridine or N-alkyl-α-pyridonimine type, the positive charge is probably distributed between both nitrogen atoms, the greater share of the charge being concentrated on the ring nitrogen in both cases. The groups formed in salts of this type differ in nature (valency state of the nitrogen atom) from the NH_2 groups of α-aminopyridine or aniline.

3. It is probable that, in the crystalline state, salts of the aniline hydrochloride type are not true salts characterized by the ionic structure $-\overset{+}{N}H_3\overline{Cl}$, but are stable saltlike molecular compounds.

BRIEF COMMUNICATIONS

DIPOLE MOMENTS OF DERIVATIVES OF 1,3,5-TRINITROBENZENE

E. A. Shott-Lvova and Ya. K. Syrkin

We have measured the dipole moments of 2,4,6-trinitrotoluene, 2,4,6-trinitro-m-xylene, and styphnic acid in benzene solution at 25° by the heterodyne beat method. The investigated ranges of concentration (in mole fractions) were 0.00487-0.01324, 0.00229-0.00333, and 0.00137-0.00142, respectively. Calculation by the Hedestrand method gave average values of α of 1.309, 2.742, and 2.32, respectively.

As is well known, in order to obtain the orientation polarization it is necessary to subtract the electron and atom polarizations from the total polarization P_∞. The value of R_D can be found from bond refractions. In order to determine the extrapolated value of the electron polarization it is necessary to know the refraction at various wavelengths. We carried out the extrapolation by subtracting the appropriate atomic increments, as given in the literature, from R_D. We consider that this gave us an upper limit for R_∞, since the difference between R_∞ and R_D is generally higher in aromatic derivatives than in other compounds.

In our case atom polarizations are of greater importance; they are fairly large, and if they are not taken into account high values of dipole moments may be obtained. For example, in a paper by C. Le Fevre and R. Le Fevre [1] the authors substracted R_D from P_∞ for trinitrotoluene and obtained a value of 1.37 D for the dipole moment. They regard this moment as "apparent", since the atom polarization is not taken into account.

The atom polarizations of nitro derivatives of benzene attain considerable values. For nitrobenzene Cartwright and Errera [2] obtained a value of 3.8 cc, and according to Coop [3] a value of 8.2 cc must be assumed for p-dinitrobenzene. For trinitrobenzene the difference between P_∞ and R_D is 9.6; when the refraction is extrapolated the difference is not less than 11.7. This indicates that one nitro group contributes, on the average, 4 cc. The atom polarization of toluene is 1 cc.

These considerations enable us to estimate the atom polarizations of our compounds to be 13, 14 and 12 cc, respectively. When these are compared with the atom polarizations of p-benzoquinone and chloranil [4], it appears that they will probably be close to the true values. Below we give a table showing our results. It is probable that the error in the orientation polarization is within ± 2 cc. If this is so, then the dipole moments are accurate within ± 0.04 D. The values obtained for the moments are more accurate than those obtained without any account being taken of atom polarization.

TABLE

Trinitrobenzene derivative	P_∞	R_D	R_{extrap}	P_{at}	P_{or}	$\mu \cdot 10^{18}$
$(CH_3)C_6H_2(NO_2)_3$ (1, 2, 4, 6) 2,4,6-Trinitrotoluene	87	48.7	46.5	~13	27.5	1.15± 0.04
$(CH_3)_2C_6H(NO_2)_3$ 2,4,6-Trinitro-m-xylene	135	53.3	51	~14	70	1.83± 0.03
$(HO)_2C_6H(NO_2)_3$ (1,3,2,4,6)	106.4	47.3	45.2	~12	49.2	1.5± 0.03

As can be seen from the table, the dipole moment of trinitrotoluene is almost three times as great as that of toluene. If the three nitro groups have a coplanar arrangement, their moments will cancel out. The presence of the nitro groups increases the positive charge on the hydrogens of the methyl group owing to the displacement of electrons toward the oxygen atoms and their "smearing out" over these atoms. These displacements can readily be represented either by arrows or by structural schemes. The increased electropositive character of the hydrogens is shown

also by the fact that trinitrotoluene readily reacts with the $C_6H_5O^-$ ion with formation of C_6H_5OH and the negative ion $[CH_3C_6H_2(NO_2)_3]^-$. This reaction has an activation energy of 13,600 cal [5].

The high value of the dipole moment of trinitro-m-xylene should be noted. If the two CH_3 groups are oriented at an angle of 120°, then the vector sum of their moments is equal to the moment of a single group. It would appear that, as we pass from 2,4,6-trinitrotoluene to 2,4,6-trinitro-m-xylene, the part played by the internally ionized state becomes more important

The dipole moment of resorcinol is 2.07, and the experimentally found moment for styphnic acid is less than this. This is the result of the configuration of the two hydroxyls, which form two hydrogen bonds. Under these conditions their rotation is highly inhibited.

SUMMARY

1. The dipole moments of 2,4,6-trinitrotoluene, 2,4,5-trinitro-m-xylene, and styphnic acid were measured.

2. The high values found for trinitrotoluene and trinitro-m-xylene are to be explained by the influence of the nitro groups.

3. It was shown that in these cases it is essential to take atom polarization into account.

SELECTIVE ACTION OF CATALYSTS PREPARED FROM NICKELOUS OXIDE TREATED WITH STEAM UNDER PRESSURE

L. Kh. Freidlin, A. A. Balandin, and N. V. Borunova

We have shown recently that, when a mixture of nickelous and aluminum oxides is treated with steam under pressure, a recrystallization process occurs, and the nickel-alumina catalyst obtained from it by reduction with hydrogen is almost completely inactive in the hydrogenation of benzene at ordinary pressure.

It is known that, in presence of a nickel catalyst, double C = C and C = O bonds are more readily hydrogenated than an aromatic bond [1]. It might be expected that a catalyst prepared from a recrystallized mixture of oxides would still preserve some activity in the hydrogenation of olefins and carbonyl compounds. With this in view we investigated the possibility of hydrogenating styrene, 3-octene, and acetone in presence of such catalysts.

EXPERIMENTAL

The catalysts were prepared by coprecipitation of a mixture of molar solutions of the nitrates with 30% sodium hydroxide solution. The resulting mixture of hydroxides was washed with water and dried at 110-125°. After decomposition the composition of the oxide mixture was 35% of NiO and 65% of Al_2O_3 (or 65% of MgO). Some samples of nickelous oxide on carrier were not steam-heated; catalysts prepared from these by reduction at 350° were highly active: when benzene was hydrogenated in their presence at 120° and at a space velocity of 0.3 hr^{-1}, the extent of conversion exceeded 90%. The remainder of the samples of nickelous oxide on carriers were treated either with steam at 100 atm in an autoclave or with a mixture of steam (100 atm) and hydrogen (700 atm) in a special high-pressure reactor for five hours at 350°, and they were then reduced with hydrogen at 350° for 13-33 hours at ordinary pressure.

The activities of the catalysts in hydrogenation reactions were determined by the usual methods — in a flow system or in an autoclave. Styrene (b.p. 145-146°, n_D^{20} 1.5450), in admixture with benzene (1 : 1), was hydrogenated at 160° and at a space velocity of 0.6 hr^{-1} over a catalyst prepared from NiO/MgO which had been first treated with a mixture of steam and hydrogen for five hours. The extent to which the ethylene bond was hydrogenated, calculated from the bromine value of the catalyst, was 96.8%. The catalyzate had n_D^{20} 1.5002, i.e. the aromatic bonds were not hydrogenated (Experiment 13).

3-Octene (b.p. 123°, n_D^{20} 1.4128; and bromine value 138.7) was hydrogenated at 130° at a space velocity of 0.3 hr^{-1}. The extent of hydrogenation was determined bromometrically. Over a catalyst prepared from NiO/Al_2O_3 treated with a mixture of steam and hydrogen, 3-octene was hydrogenated to the extent of 83.9% (Experiment 3). Over a catalyst prepared from NiO/Al_2O_3 treated with steam in absence of hydrogen, 3-octene was hydrogenated to the extent of only 42.9% (Experiment 7). Over a catalyst prepared from NiO/Al_2O_3 treated with steam at the lower temperature of 300°, the extent of the hydrogenation of 3-octene was 90.1% (Experiment 9).

Piperylene (50 ml; b.p. 42-43°; n_D^{20} 1.4395) was hydrogenated at 100-150° for four hours in a rotating autoclave at an initial hydrogen pressure of 70 atm in presence of 12 g of catalyst prepared from NiO/Al_2O_3 treated with steam. The extent of the hydrogenation of the piperylene, as calculated from the bromine value of the catalyzate, was 93.2% (Experiment 6).

Acetone (b.p. 56° and n_D^{20} 1.3592) was hydrogenated at 210° at a space velocity of 0.3 hr^{-1} over a catalyst prepared from NiO/Al_2O_3 treated with a mixture of steam and hydrogen. The extent of hydrogenation, determined by the hydroxylamine hydrochloride method, was 44.3% (Experiment 11); it was 61% over a catalyst prepared from similarly treated NiO/MgO (Experiment 14). Over a catalyst prepared from NiO/Al_2O_3 treated with steam in absence of hydrogen, acetone was not hydrogenated at 150°, even under a pressure of 100 atm (Experiment 5).

As will be seen, catalysts prepared from nickelous oxide that has been recrystallized on a carrier, which are completely inactive in the hydrogenation of benzene, exhibit considerable activity in the hydrogenation of ethylene and carbonyl double bonds. It is probable that the hydrogenation of benzene is retarded owing to the inadequate power of these poorly dispersed catalysts to activate hydrogen at ordinary pressure. In order to verify this view, we carried

Selective Action of Catalysts Prepared from Steam-treated Nickelous Oxide

* Treated with steam at 300°.

out experiments on the hydrogenation of benzene at a high pressure of hydrogen. It was found that benzene (100 g), in presence of a catalyst (15 g) prepared from NiO/Al_2O_3 previously treated with a mixture of steam and hydrogen, was not hydrogenated at 180° not only at ordinary pressure, but also at a hydrogen pressure of 40 atm. However when the hydrogen pressure was raised to 100 atm, the benzene was completely hydrogenated at 170° (Experiment 2). These results are in accord with the view that the rate of the hydrogenation of benzene over recrystallized nickelous oxide catalysts is indeed limited by the activation of the hydrogen, and not the activation of the benzene. With increase in pressure the surface occupied by the active form of hydrogen increases [2]. In presence of a catalyst prepared from NiO/Al_2O_3 treated with steam in absence of hydrogen, benzene is not hydrogenated, even under a pressure of 100 atm at 170° (Experiment 4).

Catalysts prepared from nickelous oxide treated in one case with steam and in another case with a mixture of steam and hydrogen were all equally inactive at ordinary pressure, but they varied in activity in the hydrogenation of benzene under pressure (Experiments 2 and 4). Catalysts prepared from nickelous oxide treated with steam at 300° and 350° differed in activity in the hydrogenation of 3-octene (Experiments 7 and 9).

SUMMARY

By the use of various conditions in the aging of nickelous oxide on a carrier by means of a steam treatment it is possible to control the activity of the nickel catalyst prepared from the nickelous oxide so that it loses its ability to hydrogenate an aromatic bond, but preserves its activity in the hydrogenation of double C = O bonds.

OXIDATION POTENTIALS OF ORGANIC SULFUR COMPOUNDS •

V. G. Lukyanitsa and G. D. Galpern

A knowledge of the values of the oxidation potentials of organic compounds is of great theoretical and practical importance, particularly for the petroleum and petrochemical industries, in which oxidative methods of purification, treatment, and alalysis have received extensive application. For the rational control of these processes it is essential that account should be taken of the oxidizabilities of the individual components of the material being treated or analyzed. A knowledge of the oxidation potentials of caustobiolites and of the rocks in which they occur is important for the solution of problems relating to the origin and metamorphism of petroleums and coals [1, 2]. Numerous workers have made not very successful attempts to determine the oxidation potentials of irreversibly oxidizable substances by indirect methods [3, 4, 5].

In the present investigation we have successfully used the differential potentiometric method recently proposed by Gorbachev and Vabel [6] for the determination of the oxidation potentials of organic sulfur compounds of various classes and certain hydrocarbons. The results that we have obtained in the investigation of 24 sulfur compounds and 5 hydrocarbons are given in the table.

It follows from the results given in the table that the oxidation potentials of sulfur compounds of different groups (thiols, sulfides, disulfides, and thiophenes) are marked off fairly clearly from one another. The variations in the values of the potentials which can be attributed to the variation in the structure of the hydrocarbon radicals attached to sulfur are considerably less than the variations from one group to another. The oxidation potential of thiophene is higher than that of its homolog, a fact that can be associated with the differences in oxidizability that have frequently been noted between these compounds [7].

The oxidation potentials of hydrocarbons were found to be considerably higher than those of the majority of the sulfur compounds. With respect to oxidation potential and rate of oxidation, the thiophenes approach the aromatic hydrocarbons. It should be noted that the rate of oxidation of hydrocarbons is considerably lower than the rate of oxidation of saturated sulfur compounds. Mesitylene and bicyclohexyl do not oxidize at all under these conditions.

TABLE

Within the limits in which oxidizabilities of organic compounds are determined by their oxidation potentials, it must be regarded as theoretically possible to effect the selective oxidation of sulfur compounds in presence of aromatic hydrocarbons. It is also possible to effect the selective oxidation of particular groups in sulfur compounds. In particular, the present investigation has provided a theoretical basis for the oxidative method for the determination of sulfides in various petroleum products in presence of sulfur compounds of other groups [8, 9].

SUMMARY

It was established for the first time that the irreversible oxidation potentials of thiols are about + 0.2, the values for sulfides + 0.35, for disulfides + 0.39, for thiophenes + 0.41, for di- and tri-cyclic aromatic hydrocarbons from + 0.42 to + 0.58, and for hydrocarbons of the benzene series above + 0.58.

CURRENT EVENTS

THIRD ALL-UNION CONFERENCE ON PHYSICOCHEMICAL ANALYSIS

The Third All-Union Conference on Physicochemical Analysis, which was arranged by the N. S. Kurnakov Institute of General and Inorganic Chemistry and the A. A. Baikov Institute of Metallurgy of the Academy of Sciences of the USSR, took place in Moscow on June 1-4. The conference was devoted to an appraisal of the achievements of physicochemical analysis during the five years that had passed since the Second Conference and to the marking out of the directions of future development in this original branch of general chemistry, which was brought into being as the result of the efforts of Academician N. S. Kurnakov and the very eminent Soviet school of inorganic chemists that he created.

Physicochemical analysis has found extensive application in various fields of the national economy of the Soviet Union; it is a decisive, and sometimes the only, method for the study of the nature and properties of alloys, silicates, complex mineral fertilizers, and systems formed by organic substances, for the investigation of highly important manufacturing processes concerned with the treatment of mineral raw materials, and for the preparation of various salts and metals.

Without exaggeration, the conference could be called a congress of inorganic chemists. About 700 people took part in the plenary session, and of these 250 chemists came as representatives of chemical institutes and laboratories of 44 cities and industrial centers of our country.

Over 150 papers were submitted to the organizing committee, which selected 66 for discussion. Five papers were read at the two plenary sessions, and the remaining papers at the sessions of the five sections: General, Methods of Investigation, Salts, Metals, Simple Compounds and Silicates. Altogether, 117 joined in the discussions. Great interest and lively discussion were aroused by papers devoted to fundamental questions relating to the future development of physicochemical analysis and, in particular, to problems in the modern theory of solutions, to Kurnakov's teaching on daltonides and berthollides, on the chemical individual, on the use of new methods in physicochemical analysis, etc. It was pointed out in Academician G. G. Urazov's paper "The Present State of Physicochemical Analysis and the Directions of its Future Development" and in other papers read and discussed at the conference that in the last five years a very large amount of work had been done by a team of chemists of the school of physicochemical analysis in the performance of the historic tasks set by the Nineteenth Congress of the Communist Party and under the guidance of the resolutions of the Party and the Government on the further development of industry and agriculture. The theory and methods of physicochemical analysis have been extensively applied by various research institutes, universities, and works laboratories of our country for the solution of scientific and practical problems.

Important results have been obtained in the study of the phase diagrams of light, rare, and refractory metals, and some new methods have been developed for the preparation of certain metals in a state of high purity. Physicochemical investigations have been made of the natural salts from new sources in the Kazakh, Povolzhe, Tuva, Kirghiz and other districts with the object of providing a scientific basis for the treatment of the natural salts and their utilization in the national economy. Fusion diagrams of anhydrous salts have been investigated in connection with their application as heat carriers in quenching baths and for other purposes. Some new methods for the preparation of peroxy compounds have been worked out.

During the last five years, six volumes of the Bulletin of the Sector of Physicochemical Analysis have been published, and these contained about 250 original papers in the field of physicochemical analysis. Some monographs and general reviews have also been published on the physicochemical analysis of metals and alloys and of salts of organic systems, and on other topics.

In addition to these achievements in the field of physicochemical analysis, some shortcomings were also noted by the conference. Insufficient attention has been devoted to the structure of phases of different compounds of variable composition and to the study of the crystal structures of alloys and semiconductors. Very important new methods in which labeled atoms, electron microscopy, X-ray diffraction at high and low temperatures, etc, are applied, are being adopted very slowly in scientific research. The investigation of alloys having special physical properties (heat-

stable alloys, semiconductors, alloys of rare-earth metals, etc.) is to a large extent lagging behind the requirements of the national economy and of modern technology. Insufficient attention has been given to the scientific basis of the chemical-complex treatment of mineral salts and ores.

At the plenary sessions very lively discussions followed the extremely interesting papers by Prof. B. M. Kedrov (The Subject Matter of Physicochemical Analysis, and Its Place in Science), by Prof. V. K. Semenchenko (Fundamental Problems in the Modern Theory of Solutions), by Prof. G. B. Boky (N. S. Kurnakov's Teaching on Daltonides and Berthollides in the Light of E. S. Fedorov's Theory of Crystal Structure), and by Prof. B. F. Ormont (The Theory of the Chemical Individual and some Fundamental Laws of Chemistry). The discussion on Prof. Boky's paper was continued at the Section of Physicochemical Analysis of the Scientific Council of the Institute of General and Inorganic Chemistry of the Academy of Sciences of the USSR. Some of the fundamental questions of physicochemical analysis dealt with in the papers had been discussed previously at special conferences arranged in recent years by the Kurnakov Institute of General and Inorganic Chemistry of the Academy of Sciences of the USSR on the subjects of Solid Solutions (1944), The Theory of Alloys (1952), The Definition of the Concept of the Chemical Compound (1953), and Crystal Chemistry (1953). At the conference on crystal chemistry the matters discussed included the systematics of intermetallic phases and the crystal chemistry of solid solutions. It must be pointed out, however, that these discussions have, as yet, received very little consideration in our chemical journals.

Many of the papers read at the sectional sessions were received with great interest and prompted a lively exchange of opinions. We must mention in particular interesting papers on the physicochemical analysis of solutions (N. A. Izmailov), the structure of solutions (O. Ya. Samoilov and M. I. Shakhparonov), the chemical nature of substances (D. A. Petrov), the physicochemical theory of plasticity (S. I. Gubkin), the application of radioactive indicators in physicochemical analysis (A. V. Nikolaev), the investigation of diffusion in binary alloys as a new method of physicochemical analysis (M. B . Neiman and A. Ya. Shinyaev), ultrasonics and its application in the physicochemical analysis of alloys (N. T. Gudtsov and M. N. Gavze), the physical properties of salt melts and the nature of their structural particles (N. P. Luzhnaya, N.N. Evseeva, and I. P. Vereshchetina), the character of the solubility of dolomite in water and gypsum solutions at different partial pressures of carbon dioxide (O. K. Yanatyeva), and the solubility of sparingly soluble salts in aqueous solutions of electrolytes (E. B. Shtemina and E. V. Frolova).

The conference expressed the hope that the papers and discussion would be published very promptly. Discussions of the fundamental questions of physicochemical analysis should form a feature of the new journal " Inorganic Chemistry", which is to start publication in 1956.

With a view to the development of physicochemical analysis and its application to the solution of very important scientific and national problems and with a view to the rapid application of the achievements of science in industry, the conference, in its resolutions, marked out a program for further investigations and pointed out the need that action should be taken in the following directions:

1. Research on methods of representing multicomponent systems, on the theory of chemical diagrams, and on the application of thermodynamics and statistical physics in physicochemical analysis.

2. The intensification of the experimental and theoretical study of liquid and solid solutions having metals, salts, organic substances, oxides, and silicates as components. Particular attention must be given to the structure of solutions.

3. Special attention must be turned on the application in physicochemical investigations of new methods (labeled atoms, ultrasonics, magnetic methods, optical methods, electron microscopy, and X-ray diffraction at different temperatures) for the study of phase diagrams, phase transitions, and crystal structure. One of the most important problems of the school of physicochemical analysis is to provide a collection of monographs on the methods of physicochemical analysis, and also to encourage the wider use of methods of representing complex multicomponent systems which are applicable to metallurgy, halurgy, the petrography of salts, geochemistry, hydrochemistry, and geology.

4. In the application of physicochemical analysis to the investigation of alloys -- the further development of work on the investigation of the phase diagrams, structures, and properties of heat-stable alloys, high-strength light alloys, semiconductors, and alloys of rare metals, and on the preparation of metals of high purity and the determination of their physicochemical constants.

The conference pointed out that investigations in this direction must be intensified at the A. A. Baikov Metallurgy Institute of the Academy of Sciences of the USSR, and other similar institutes and laboratories, and must be resumed at the N. S. Kurnakov Institute of General and Inorganic Chemistry of the Academy of Sciences of the USSR.

5. In the field of the physicochemical analysis of salt systems and the investigation of natural salts – the further development of work on the study of the structures and thermodynamic properties of salts and salt melts and on the study of equilibria in aqueous salt solutions and salt melts with further increase in the number of components and in the range of the variables (temperature and pressure) determining the equilibrium.

Special attention must be paid to the physicochemical study of the rich salt deposits in the new salt-bearing districts of the country (Belorussian SSR, W. Kazakh, Povolzhe. the Eastern Provinces), and work must be continued on the investigation and utilization of the natural salts of Kara-Bogaz-Gol, Kirghiz, and the salt lakes of W. Siberia, Prikaspie, and Priaralye.

6. The further development of investigations on the scientific basis of the synthesis of peroxy compounds, boron compounds, hydrides, and other compounds, and on the study of oxides, hydroxides, carbides, nitrides, sulfides, selinides, and tellurides of various elements, particularly rare elements.

The conference resolved that it was desirable to arrange special conferences in the near future on problems in the chemistry of alloys, the physicochemical analysis of salt systems and natural salts, the chemistry of molten salts, the physicochemical analysis of peroxy compounds, and the theory of solutions. It was pointed out also that it was essential to continue the discussion of the controverial issues relating to the definition of the concept of the chemical individual, the compound, the phase, the component, etc.

In order to achieve a more extensive introduction of physicochemical analysis into the teaching practice of universities, it is necessary to widen the scope of the relevant programs and courses on general, inorganic, and physical chemistry.

A resolution carried by the conference reflected the views expressed by many participants regarding the necessity for greater coordination of investigations in the field of physicochemical analysis, which must be included in the coordination plan of the chemical institutes of the Academy of Sciences of the USSR, the Academies of Sciences of the various republics, branch institutes, and laboratories carrying out research in this direction.

The conference called upon scientists working in the field of physicochemical analysis to strengthen still more the link between science and industry and, in collaboration with industrial workers, press on still more arduously with the introduction of scientific achievements and the application of modern technology in the service of the national economy.

UNUSUAL VALENCIES OF SOME METALS

B.V. Nekrasov

(Paper Read at a General Meeting of the Division of Chemical Sciences of the Academy of Sciences of the USSR, October 27, 1955)

In the well known classical treatment, the term "valency", applied to a given element, is understood to refer merely to the number of valency bonds (usually covalent bonds) formed by an atom of the element with other atoms in the molecule. However, in inorganic chemistry there is also the old and firmly established concept of positive and negative valency, which characterizes numerically the assumed degree of oxidation of the given atom in the chemical compound. These two definitions of valency are not always equivalent; we have, for example, the hydrogen peroxide molecule H–O–O–H, in which oxygen is bivalent in the first sense and negatively univalent in the other. In the following discussion we are concerned with the degrees of oxidation of the elements.

In recent years the study of compounds corresponding to unusual degrees of oxidation of elements, particularly metals, has been appreciably intensified. Some of the results obtained are of great interest from various points of view. In the present paper it is, of course, impossible to discuss, even briefly, all of the achievements in this field, and we shall therefore deal with only a few individual metals.

Perhaps the most interesting from the theoretical point of view is the discovery and preparation of negatively univalent rhenium. A degree of oxidation of −1, so characteristic for the halogens but never previously detected with certainty in a metal, was first established for rhenium in 1937 [1] in the product of the reduction of potassium perrhenate by amalgamated zinc in cold, very dilute solution and in complete absence of air:

$$KReO_4 + 4Zn + 5H_2SO_4 \rightarrow HRe + 4ZnSO_4 + KHSO_4 + 4H_2O.$$

The resulting solution readily reduced silver and copper salts to the metal, and the fact that Re^{1-} was indeed present in the solution was established oxidimetrically.

Further investigations by various authors [2] fully confirmed these early results, but neither hydrogen rhenide nor any of its salts were isolated until quite recently.

The first suggestion for the electronic structure of rhenium in this unusual state of oxidation of −1 was made by Lingane in 1942 [2], who considered that the transition from the neutral atom Re to the ion Re^- is accompanied by the following change in the structure of the outer electron shells:

However, such a mass transfer of electrons from the 5d level to the 6p level requires an enormous activation energy and is therefore extremely improbable.

A further suggestion was made in 1947 by Pauling [3], who based his treatment on the isoelectronic structure of the ions Pt^{2+} and Re^-. As it is characteristic of bivalent platinum to exist in the form of complex compounds in which it has a coordination number of four (dsp^2 hybridization), Pauling considered that the Re^- ion must be stabilized by four ligands at the corners of a square (in aqueous solution the ligands will probably be

water molecules). Pauling's structure corresponds to the following schemes of electron distribution in the outer shells:

It will be seen from these schemes that the isoelectronic ions themselves – Pt^{2+} and Re^{-} are not structurally of the same type, but identity of type may be attained (if it really is attained) by the coordination of four ligands. These views imply that rhenium hydride and all of its derivatives can exist only as complex compounds, differing fundamentally in this respect from hydrogen halides and their salts.

In order to verify these concepts it was obviously necessary to prepare a rhenide in the pure state. An attempt, made in 1950, to prepare thallium rhenide [4] was not successful, but in 1952 a white precipitate containing potassium rhenide and KOH was obtained by the reduction of $KReO_4$ with potassium in a medium consisting of water and ethylenediamine (about 10% of water), the reaction being carried out in an atmosphere of nitrogen [5]. In 1954, by extraction of the caustic potash with isopropyl alcohol, the authors succeeded in obtaining a grey solid corresponding in composition approximately to $KRe \cdot 4H_2O$ (in admixture with only about 5% of KOH) [6]. They established that this substance is feebly paramagnetic, and they considered that its structure is probably that proposed by Pauling. It is interesting that a solution containing KRe can apparently be prepared also by heating the product of the direct action of potassium on rhenium with water at reduced pressure in absence of air [7].

Somewhat earlier (1953) a white crystalline lithium rhenide, readily soluble in water, was isolated, probably as a hydrate, by crystallization from an aqueous solution containing the product of the reduction of $KReO_4$ with lithium [7]. Its structure was not investigated, but it was shown that LiRe itself, and also its alkaline solutions, is quite stable in an atmosphere of nitrogen, but is slowly oxidized by air. In hydrochloric acid it rapidly reduces $BiCl_3$ to the metal, in an alkaline medium it reduces TlOH in a similar fashion, and it is oxidized quantitatively to perrhenate by acid permanganate.

These results confirm the acid character of hydrogen rhenide, which has not yet been isolated in the pure state. The question arises of for which other metals may the existence of similar compounds be most reasonably expected. One naturally turns to the nearest analogs of rhenium – technetium and manganese. However, owing to the lanthanide contraction, in the rhenium atom the effective positive field should be more powerful than in Tc and Mn atoms, i.e. the tendency of the latter to take up an electron will be less.

Tungsten – the neighbor of rhenium in the period – offers greater promise from the point of view of the possibility of the isolation of a hydride analogous to a hydrogen halide. In fact, as indicated in the schemes given below, the rhenium atom, in forming a covalent bond with hydrogen, requires activation, whereas the tungsten atom does not (and moreover, its 5d subgroup remains exactly half-full).

It should be noted also that in the tungsten atom the effective positive field is more powerful than in the rhenium atom – a fact that follows from the values of their first ionization potentials, which are 8.0 V and 7.8 V respectively (whereas for manganese the value is only 7.4 V). It would be of interest to attempt the preparation of the hydride HW and its derivatives, making use of the experience already gained in work on rhenium hydride.

The rhenium analog, manganese, and its neighbors in the period, chromium and iron, are very well known elements, and it might be thought that our knowledge of their chemistry has long been very thorough and complete. However, in recent years there have been some interesting investigations that throw new light on certain degrees of oxidation of these metals. In the following comparative table the degrees of oxidation that can be regarded as unusual are underlined:

Cr	0	<u>+1</u>	+2	+3	<u>+4</u>	<u>+5</u>	<u>+6</u>
Mn	<u>0</u>	<u>+1</u>	+2	+3	<u>+4</u>	<u>+5</u>	<u>+6</u>
Fe	<u>0</u>	<u>+1</u>	+2	+3	<u>+4</u>	<u>+5</u>	<u>+6</u>

Whereas for chromium and iron a degree of oxidation of zero has been known for a long time in the simple carbonyl derivatives $Cr(CO)_6$ and $Fe(CO)_5$, the synthesis of a manganese carbonyl was not accomplished until 1954 [8]. Volatile golden-yellow crystals of $[Mn(CO)_5]_2$ were obtained treating a suspension of MnI_2 with magnesium in ether at room temperature in presence of carbon monoxide at a pressure of 2000 atm. In composition (and structure) this compound is analogous to the rhenium carbonyl prepared in 1941 [9].

A substance that can be regarded as an intermediate compound in the transition from Mn^0 to Mn^{+1} was prepared in 1953 [10], namely, a pale-yellow substance of composition $K_{11}Mn_2(CN)_{12} \cdot 2NH_3$ or $K_4[Mn(CN)_6] \cdot K_5[Mn(CN)_6] \cdot 2NH_3$, which is precipitated when $K_4[Mn(CN)_6]$, as a solution in liquid ammonia, is reduced with potassium. The composition of the precipitate was established by analysis and by oxidimetric estimation (by reduction of Ag^+ in ammoniacal solution). As would be expected, the compound is paramagnetic (the one unpaired electron of Mn^0), but instead of the theoretical value of 1.73 magnetons, a moment of only 1.25 magnetons was found experimentally, this being explained by the authors as due to partial oxidation of the precipitate. This is a very likely explanation, but it is even more likely that the substance is not a definite stoichiometrical compound and is of variable composition, being formed by the incomplete reduction of the original complex cyanide. If this is so, then we may hope to accomplish the direct preparation of $K_5[Mn(CN)_6]$, which would not only confirm the existence of Mn compounds, but also increase the number of the "cyanyls" predicted in 1940 by Ormont [11], the first of which were nickel [12] and palladium [13] compounds of general formula $K_4[M(CN)_4]$, which were synthesized in 1942 and 1943, respectively.

The question of a degree of oxidation of +1 for manganese is not altogether clear. In 1927 [14] some colorless crystals were obtained by the vigorous reduction of a violet aqueous solution of $K_3[Mn(CN)_6]$ with aluminum powder in an atmosphere of hydrogen, and, on the basis of elementary analysis and oxidimetric estimation, these were assigned the formula $K_5[Mn(CN)_6]$. A compound of this composition should be diamagnetic, like $K_4[Fe(CN)_6]$, but it was shown in 1940 [15] that this compound has a fairly high magnetic moment (not less than 1.04 magnetons). It would appear that the substance investigated had a higher or lower degree of oxidation. It may be assumed that the compound $Mn(CO)_5I$ – prepared in 1954 [8] in the form of ruby-red crystals, readily oxidized by air, by treating manganese carbonyl with iodine – is another Mn^{+1} derivative.

The first compound of positively univalent chromium was prepared as recently as 1952 in the form of a complex compound with 2,2'-bipyridyl by reduction of a red solution of $[CrBipy_3](ClO_4)_2$ with magnesium powder, zinc dust, or sodium amalgam. The product was a blue-black powder of composition $[CrBipy_3]ClO_4$, which was insoluble in water and very readily oxidized by air. A value of 2.0-2.1 magnetons was found for its magnetic moment, which is close to the theoretically expected value of 1.73 magnetons (the discrepancy is probably due to partial oxidation). In the same year (1952), experiments were carried out on the reduction of $K_3[Cr(CN)_6]$ – as a yellow solution in liquid ammonia – with potassium, and a dark-brown precipitate was formed which, according to determinations of its reducing power (reduction of Ag^+), contained positively univalent chromium. This work, which was carried out by Colton, has not been published, but has been mentioned in a paper by other authors [17].

Iron compounds having an apparent degree of oxidation of +1 have been long known in the form of various nitroso complexes, such as $Na_2[Fe(CN)_5NO]$. The formation of some of these is accompanied by appreciable evolution of heat, this being true, for example, of the reaction:

$$2FeI_2 + 4NO \rightarrow 2Fe(NO)_2I + I_2.$$

The resulting black-brown compound volatilizes without decomposition, but is very unstable to water and air. The magnetic properties of this nitroso complex have not been studied, but some other compounds of this type

have been found to be diamagnetic in spite of the fact that Fe^{2+} ions and neutral NO molecules contain unpaired electrons. In particular, there is the red salt corresponding in composition to $K[Fe(NO)_2S]$, which is shown by X-ray analysis to be dimeric, the ion $[(NO)_2FeS_2Fe(NO)_2]^{2-}$ consisting of two tetrahedra having a common side formed by sulfur atoms, iron atoms at the centers, and NO molecules at the external corners. As it is possible in principle for the NO group to function not only as a neutral molecule, but also as a positive or negative ion (NO^+ or NO^-), it must be acknowledged that the question of the actual degree of oxidation of iron in its nitroso derivatives is still open and demands further investigation.

A cyanide complex of positively univalent iron appears to be formed by electrolytic reduction of $K_3[Fe(CN)_6]$ in solution in presence of an excess of potassium cyanide [18], but it has not been isolated. An Fe^{3+} derivative of very simple composition was prepared in 1940 [19] by the slow decomposition of the carbonyl complex of ferrous iodide in a current of carbon dioxide, which proceeds in successive stages, as follows:

$$Fe(CO)_4I_2 \rightarrow Fe(CO)_2I_2 \rightarrow Fe(CO)_2I \rightarrow FeI.$$

The final product was an extremely unstable bright-red powder; a yield of only a few milligrams was obtained, and the compound was not studied in detail. As this discussion shows, the existence of Fe^{3+} compounds has not yet been proved convincingly.

The position with regard to Fe^{4+} compounds is somewhat better, but is again not altogether clear. Already at the beginning of this century [20], black amorphous powders analyzing essentially as $BaFeO_3$ were prepared by heating mixtures of $Fe(OH)_3$ with barium or strontium hydroxide in a current of oxygen. These "perferrites" were studied further until 1952 [21], when some meta and ortho compounds of this type were prepared in the pure state not only from tervalent, but also from sexavalent iron. It was shown, in particular, that when red $BaFeO_4$ is kept, spontaneous elimination of oxygen occurs with formation of black $BaFeO_3$. The other "perferrites" that have been prepared are also black microcrystalline powders. X-Ray analysis of Ba_2FeO_4 showed that the crystals are of the same type as those of Ba_2TiO_4, which, in conjunction with elementary and oxidimetric analysis, indicates the presence of quadrivalent iron. However, the results of an investigation of the magnetic properties of these substances [21] have not yet been published. It should be noted also that both in its simple and in its complex fluorine compounds, iron fails to manifest this valency [22]. The above-mentioned salts, therefore, are as yet the only known Fe^{4+} compounds.

Chromium in the same state of oxidation (+4) was obtained in the form of its fluoride CrF_4 in 1941 by the action of fluorine on CrF_3 at 400° [23]. This substance is a fairly volatile amorphous brown substance; it deliquesces in moist air and is decomposed by water with formation of ter- and sexa-valent chromium compounds. An analogous solid brown chloride $CrCl_4$ was obtained in 1942 [24] by "freezing" a high-temperature gas-phase equilibrium, which under ordinary conditions rapidly moves in the direction $2CrCl_4 \rightarrow 2CrCl_3 + Cl_2$. In 1949 [22], a yellow complex fluoride $K_2[CrF_6]$ was prepared by the fluorination of the mixture $2KCl + CrCl_3$, and the X-ray diffraction pattern given by this substance was found to be quite analogous to that of the corresponding yellow compound of quadrivalent manganese, $K_2[MnF_6]$.

Black CrO_2, which was prepared as early as 1908 [26] by heating $Cr(OH)_3$ in the air at not above 400°, was shown by a magnetic study in 1953 [27] to be a Cr^{4+} compound, and not a basic chromium chromate $(CrO)_2CrO_4$. Barium and strontium salts of the acid corresponding to CrO_2 were not prepared until 1952-53 [21]. The first of these is formed by a very interesting reaction when a mixture of Cr_2O_3 and $Ba(OH)_2$ is heated in a current of nitrogen to about 800°:

$$Cr_2O_3 + 4Ba(OH)_2 \rightarrow 2Ba_2CrO_4 + H_2 + 3H_2O.$$

It is interesting also that the strontium salt is not formed under similar conditions; it was prepared in a current of nitrogen in accordance with the reaction:

$$SrCrO_4 + Cr_2O_3 + 5Sr(OH)_2 \rightarrow 3Sr_2CrO_4 + 5H_2O.$$

Both salts are microcrystalline green powders. The quadrivalency of the chromium present was confirmed by X-ray and magnetic investigation. It follows from the above discussion that the existence of chromium at a degree of oxidation of +4 is fairly firmly established.

The evidence for the existence of a degree of oxidation of +5 for chromium is equally convincing. Red salts of the type $M_3[CrOCl_5]$ were prepared as early as 1905-1907 [28] by the partial reduction of chromium trioxide in presence of KCl, RbCl, CsCl, or NH_4Cl, with very concentrated hydrochloric acid under cooling, and

it was shown that the cesium salt gives mixed crystals with the analogous red salt of niobium, $Cs_2[NbOCl_5]$. In 1951 [29] pale-purple $K[CrOF_4]$ was prepared by reaction between $K_2Cr_2O_7$ and BrF_3, and the analogous silver salt was prepared also. Magnetic investigation [30] showed that chromium is quinquevalent also in the red perchromates of general formula M_3CrO_8 (M is a univalent metal), which were first prepared by Spitalsky [31]. The formation of traces of the highly volatile fiery-red CrF_5 has been observed both during the fluorination of chromium trifluoride [23] and in the thermal decomposition of $K_2[CrF_6]$ [25], but large amounts of this compound have not yet been prepared. Dark-brown Cr_2O_5 is apparently formed as an intermediate product in the thermal decomposition of chromium trioxide [32], but it has not yet been isolated. On the other hand, the corresponding barium and strontium salts were prepared in 1952 [21] as indicated:

$$4MCrO_4 + 2M(OH)_2 \rightarrow 2M_3(CrO_4)_2 + O_2 + 2H_2O.$$

the reactants being melted together at about 800° in a current of nitrogen. These compounds are finely crystalline blue-black powders, insoluble in water, and readily decomposed by acids with formation of ter- and sexa-valent chromium compounds. X-Ray and magnetic studies of the barium salt confirmed the presence of quinquevalent chromium [21].

As recent investigations have shown, under certain conditions a degree of oxidation of +5 is fairly characteristic for manganese. Although the first relevant compound – the green salt $Ba_3(MnO_4)_2.H_2O$ – was described as early as 1904 [33], this investigation and many others of that period were forgotten so completely that there is no mention at all of a degree of oxidation of +5 for manganese in such well known monographs and textbooks as the books of Sidgwick [34] and Remy [35]. Interest in these compounds was revived only in 1946 [36], when blue crystals of composition $Na_3MnO_4 \cdot 10H_2O$ were prepared. This substance, which was found to give solid solutions with Na_3PO_4, Na_3AsO_4, and Na_3VO_4, was prepared by the reaction of MnO_2 and Na_2O_2 in molten sodium nitrate at 500° and crystallization of the product from concentrated caustic soda solution. The presence of quinquevalent manganese in this substance was later confirmed by a study of its magnetic properties [37]. The compound is decomposed by water as follows:

$$2Na_3MnO_4 + 2H_2O \rightarrow MnO_2 + Na_2MnO_4 + 4NaOH$$

and it has some measure of stability only in cold strongly alkaline solution, in which the above reaction probably becomes appreciably reversible [36]. It was shown in 1952-53 [21] that the anhydrous dark-green salts K_3MnO_4, Na_3MnO_4, $Ba_3(MnO_4)_2$, $Sr_3(MnO_4)_2$ may be prepared also from manganates (by heating them strongly with alkalis in a current of nitrogen) and from manganese dioxide (by heating it fairly strongly with alkalis in a current of oxygen). In 1954 bluish-green Li_3MnO_4 was prepared by the reaction of $LiMnO_4$ with LiOH at 125° in a current of oxygen, and detailed studies were made of the corresponding sodium and potassium salts [38]. It should be noted, however, that attempts to prepare fluorine derivatives of quinquevalent manganese have not been successful [25].

Unlike chromium and manganese, iron has not yet been found at a degree of oxidation of +5. The most promising direction in which syntheses of such compounds might be sought lies in the cautious heating of a ferrate with a very concentrated solution of alkali, when reaction might be expected in accordance with an equation such as:

$$4Na_2FeO_4 + 4NaOH \rightarrow 4Na_3FeO_4 + O_2 + 2H_2O.$$

If such a process can indeed be realized, then the main difficulty will be the establishment of sufficiently mild conditions so that reduction of the iron will not go too far.

The comparatively small amount of material that we have examined here already shows that the study of the unusual degrees of oxidation of the elements gives results of interest and importance from the purely scientific point of view. In some cases these results are also acquiring importance in applied science. A good example is univalent aluminum (the compounds of which were reviewed recently [39]), which is beginning to play a substantial part in the development of a more rational procedure for the smelting of this metal [40]. We may expect that work on the unusual degrees of oxidation of various elements will be further intensified in the near future.

POSSIBLE MECHANISM OF THE CATALYTIC OXIDATION OF HYDROGEN ON METALS

O.V. Krylov and S.Z. Roginsky

The oxidation of hydrogen is actively catalyzed by the noble metals – platinum, palladium, ruthenium, and others – and also by some non-noble transitional metals (in the elementary state), namely, nickel, iron, copper, molybdenum, and tungsten. Various investigators who have studied this reaction have noted that the noble metals (platinum, palladium, osmium, iridium, ruthenium, and rhodium) are hundreds or thousands of times as active as the non-noble metals [1,2]. The quantitative investigation of oxidation at the surface of a non-noble metal is rendered difficult by the formation of oxide films. It was shown in the earlier investigations of 1920-30 [1,3-6] that the oxide films formed as distinct phases on non-noble metals are considerably less active in this reaction than the metals themselves. When oxygen acts upon noble metals, it undergoes chemisorption without the formation of oxide phases. However, under certain conditions of catalytic reaction the possibility of the formation of oxides at the surface of a noble metal cannot be excluded [7].

The principal kinetic laws governing the oxidation of hydrogen over platinum are as follows: 1) inactive platinum is activated by oxygen or a mixture of hydrogen and oxygen with the result that a constant, stable level of activity is attained [8-14]; 2) over wide ranges of temperatures and pressures (from −100° to +200° and from 0.01 mm to 5 mm) the rate of reaction is directly proportional to the pressure of oxygen and inversely proportional to the square root of the pressure of hydrogen [8-11]:

$$-\frac{dp}{dt} = k\frac{p_{O_2}}{\sqrt{p_{H_2}}} \qquad (1)$$

3) at pressures close to that of the atmosphere the rate of the reaction is proportional to the oxygen pressure and is almost independent of the hydrogen pressure [2,13]; 4) at temperatures above 200° the reaction may pass from the surface to the gas space [15-17], the limiting temperature being raised by reduction in pressure; 5) chemisorbed oxygen does not react appreciably with hydrogen present in the gas space at low temperatures [9,18,19], but with rise in temperature this reaction becomes appreciable; 6) adsorbed hydrogen reversibly poisons the active centers of the platinum, but in presence of the reaction mixture the poisoning rapidly disappears after a period of induction [9,10].

The behavior of the noble metals is essentially similar. This similarity in the kinetics and other features of the catalytic reaction in presence of different noble metals suggests that the mechanism is the same in each case. We have made a detailed investigation of the mechanism for the case of platinum [7-9]. This case is particularly interesting, for experiment shows that platinum behaves the same in the mass, when supported by a carrier, and in the form of a thin film [8].

In examining the mechanism of the oxidation of hydrogen over platinum, we shall start from the already established fact that the absorption of oxygen is an essential condition for the creation of a highly active surface on the noble metal [9]. The relationship of the catalytic activity of the platinum to its oxygen content is approximately linear when the oxygen content is not too high. The activating effect of a detonating hydrogen-oxygen mixture is also due essentially to the absorption of oxygen by the metal [7].

We assume, as our main postulate, that the chief obstacle to the reaction of oxygen with hydrogen is the readiness with which the oxygen passes into an inactive state – powerful sorption, resulting, in the case of non-noble metals, to the formation of phase oxides by the mechanism established by Wagner [20], Mott [21], and others. In the case of the noble metals, we shall identify this inactive state with powerful high-temperature

sorption of oxygen. The oxygen that enters into this surface compound is firmly attached to the metal and, although not reduced by hydrogen, it activates the metal with respect to the oxidation of hydrogen.

Some investigators [22-24], on the basis of data on the work required for the escape of an electron from platinum covered with oxygen, consider that the adsorbed oxygen occurs on the platinum surface in the form of atom ions O^- or O^{--}. There are some indirect data that support the formation of O_3^-. In any case, the various authors all consider that the absorbed oxygen is negatively charged. It is natural to assume that the 6s electrons of the platinum, which are the main source of its electrical conductivity, take part in the formation of these ions — O^-, O^{--}, or O_3^- — on the platinum surface. The capture of some of the s electrons should result in the freeing of some of the d electrons, so that some free places will appear in the d zone of platinum. As early as 1934 [25], one of the present authors emphasized the part played by d electrons in catalysis.

According to our results and those of others [9, 12, 19], at ordinary temperatures the adsorption of hydrogen by platinum in the mass is inappreciable. On dispersed platinum supported by a carrier, the adsorption of hydrogen is appreciable and has an activated character [26]. This view is supported by the results of a study of the effect of hydrogen on the work required for the escape of an electron from the platinum surface [27]. Taking these features of the adsorption of oxygen and hydrogen on the metal into account, we may offer some explanations of the kinetic equations that we have found:

1. When only oxygen enters the transitional complex, the kinetic equation is of the form:

$$W = k_{H_2} \cdot [O_2], \tag{2}$$

in which k depends on $[H_2]$ owing to the poisoning effect of hydrogen. The relationship expressed by Equation 1 may represent the poisoning of the active part of the metal surface, which consists of sites having identical properties, the poisoning agent — hydrogen — being dissociated during adsorption into atoms (Variant 1a). The number of active centers free for reaction with O_2 is

$$N_{act.\,free} = \frac{N_1\,act}{1 + ap^{1/2}}. \tag{3}$$

In which a is a constant and p is the gas pressure. When $ap^{1/2} \gg 1$, we obtain the relationship required*.

A similar result is obtained for a nonuniform surface with the aid of the statistical theory of poisoning [28, 29] (Variant 1b). In this case the physical meaning of the power to which p is raised is different, and this index may be less or greater than 0.5. The limits of error within which it may be determined from our data are ± 0.1. From the point of view of the usual concepts, the model of the nonuniform surface is used in both cases, but in the first variant the distribution of active sites is of a discrete character, and in the second variant it is of an extensive character.

2. The composition postulated for the activated complex is not the only one possible. The only essential feature is the entry of an undissociated oxygen molecule or oxygen ion into the complex. One could assume, for example, that absorbed hydrogen atoms entered into the transitional complex, their concentration being proportional to $[H_2]^{1/2}$ and the poisoning activity proportional to $[H_2]^{-m}$. In the case of a homogeneous surface (with respect to active centers), the retardant must be the undissociated hydrogen molecule, which does not appear very probable (Variant 2a). In the case of a nonuniform surface (Variant 2b), it must be assumed that $[H_2]$ enters into the denominator raised to a fractional power m not differing greatly from unity:

$$W = k_0 \frac{N_1}{[H_2]^m} \cdot [O_2]\,[H_2]^{1/2}. \tag{4}$$

It does not appear to be possible at present to make a final choice between Variants 1a, 1b, and 2b. An answer to this question might be provided by experiments on the oxidation of hydrogen in which hydrogen and oxygen isotopes would be employed. If the transitional complex does not contain hydrogen, then there should be no kinetic isotope effect when H_2 is replaced by D_2 or T_2, but there should be an appreciable kinetic effect in passing from $O_2^{16} + O_2^{18}$ to $O^{16}O^{18}$. The old results of Tuchloski [17] on the effect of the replacement of H_2 by D_2 on the reaction rate over Pd are not altogether unequivocal. Until more accurate data are available, both possibilities must be considered.

*In this case a includes not only the usual adsorption coefficient $a = a_0 e^{+\alpha Q}$, but also the factor K_{diss}.

On the basis of all these considerations, the first stages of the oxidation of hydrogen over platinum, including also the activation process, are very probably as follows:

1) Activation of platinum by oxygen (irreversible):

$$Pt + \tfrac{1}{2} O_2 \rightarrow Pt(O) \equiv Pt^{(O)}.$$

2) Adsorption of hydrogen on active centers (possibly with the formation of ions):

$$Pt^{(O)} + \tfrac{1}{2} H_2 \rightleftharpoons Pt \pm (O) \ldots H^{\pm}.$$

3) Activation of oxygen – the initial stage of the actual catalytic reaction, and probably the limiting stage:

$$Pt^{(O)} + O_2 \rightarrow Pt \pm (O) \ldots O_2^{-}.$$

In order to elucidate the further stages it is essential to carry out special investigations. The schemes suggested below are hypothetical and may be modified considerably in detail in the future; their common feature is the participation of charged particles* in the process and the occurrence of direct electron transitions. Several investigators have recently emphasized the importance of the part played by ionic mechanisms in catalysis [24, 30]. The possibility of ionic mechanisms for the oxidation of hydrogen over platinum follows from data on the kinetics of the oxidation of hydrogen over platinum in a solution [31, 32] and from the operation of similar laws of reaction in the decomposition of hydrogen peroxide [33].

We will write down some non-chain stages of the process:

$$4)\ O_{2\,ads}^{-} + H_2 \rightarrow O_{ads}^{-} + H_2O;$$

$$5)\ O_{ads}^{-} + H_2 \rightarrow H_2O$$

Other variants are:

$$4a \rightsquigarrow 5a)\ O_{2\,ads}^{-} + H_2 \rightarrow H_2O_2 \rightarrow H_2O + {}^1\!/_2 O_2;$$

$$4b \rightsquigarrow 5b)\ O_{2\,ads}^{-} + H \rightarrow HO_{2\,ads}^{-} \xrightarrow{+H} H_2O + O_{ads}^{-};$$

$$4c \rightsquigarrow 5c)\ O_{ads}^{-} + H \rightarrow OH_{ads}^{-} \xrightarrow{+H^+} H_2O.$$

Ionic mechanisms permit also surface chain formation, for example:

$$4d)\ O_{2\,ads}^{-} + H_2 \rightarrow O_{ads}^{-} + H_2O;$$

$$O_{ads}^{-} + O_2 \rightarrow O_{3\,ads}^{-};$$

$$O_{3\,ads}^{-} + H_2 \rightarrow O_{2\,ads}^{-} + H_2O.$$

$$4e)\ O_{2\,ads}^{-} + H \rightarrow HO_{2\,ads}^{-} \xrightarrow{+H_2} H_2O + OH_{ads}^{-} \text{ etc.}$$

Moreover, radicals may be formed and may initiate a homogeneous chain reaction (reaction in the gas space):

$$O_{2\,ads}^{-} + H_2 \rightarrow OH_{ads}^{-} + OH;$$

$$O_{ads}^{-} + H_2 \rightarrow H_{ads}^{-} + OH;$$

$$O_{2\,ads}^{-} + H \rightarrow HO_{2\,ads}^{-} \rightarrow HO_2;$$

$$O_{3\,ads}^{-} \rightarrow O_3 \text{ etc.}$$

It is probable that these considerations will be valid for other noble metals.

SUMMARY

1. An examination is made of the principal results of the study of the kinetics of the oxidation of hydro-

*The "ions" featuring in these schemes are not analogous to the ions in solutions and are probably highly polarized states of molecules and atoms.

gen in presence of platinum.

2. On the basis of a very large amount of experimental material, it is suggested that the stage limiting the process of the oxidation of hydrogen over platinum is the adsorption of oxygen without breakdown of the molecules into atoms.

3. The oxygen that forms a stable surface compound with platinum is not reduced by hydrogen, but it activates the platinum with respect to the reaction of hydrogen oxidation.

4. Suggestions are made concerning the further stages in the process of the oxidation of hydrogen over platinum.

5. The laws governing the oxidation of hydrogen over platinum apply also to palladium and other noble metals, and this fact makes it probable that the mechanism is the same in each case. Some stages of the mechanism that we have analyzed are probably to be found also in the case of the non-noble transitional metals.

INVESTIGATION OF THE ADSORPTION OF VAPORS ON QUARTZ

COMMUNICATION 2. ADSORPTION ISOTHERMS OF VARIOUS VAPORS

A.I. Sarakhov

With the aid of the apparatus described in the first communication [1] we have investigated the adsorption on highly dispersed crystalline quartz of some polar vapors – water, methanol, and 1,2-dichloroethane at 20° – and some nonpolar vapors – heptane at 20° and 40° and benzene at 20° and 25°.

The quartz was obtained from A.V. Kiselev's laboratory (Moscow State University). Its specific surface, determined from the adsorption isotherm for nitrogen at its boiling point, was 0.6 sq.m/g. X-ray analysis of this adsorbent showed that it was α-quartz having a particle size of about 0.001 cm, which, on the assumption that the particles were spherical, corresponded to a geometric surface of about 0.4 sq.m/g. The quartz was heated at 380° in a vacuum before each series of measurements.

TABLE 1

Adsorption of Water Vapor on Quartz at 20°

(a - adsorption in micromoles per gram; p/p_s - relative pressure, the value of p_s being 17.53 mm; the asterisks indicate desorption points)

a	$p/p_s \cdot 10^3$	a	$p/p_s \cdot 10^3$	a	$p/p_s \cdot 10^3$
0.093	0.00019	3.57	2.68	11.10	58.5
0.243	0.00063	3.91	3.76	11.33*	33.5
0.429	0.00274	4.43	5.82	13.18	70.2
0.672	0.00707	4.82	7.64	13.71*	57.5
0.877	0.0200	5.40	11.2	15.84	79.2
1.157	0.0530	6.03	15.8	20.04*	82.6
1.512	0.149	6.76	21.7	22.35	88.2
2.11	0.451	7.31	28.0	40.65	92.1
2.63	1.018	8.29	37.1		
3.01	1.65	9.22	45.6		

The results of the investigation are given in Tables 1-5 and are represented graphically in Fig. 1. As will be seen from Fig. 1, all of the isotherms are S-shaped, i.e. correspond to the second type of isotherms in Brunauer's classification. The adsorption isotherms for water and methanol vapors are irreversible for the desorption points (not shown in Fig. 1) do not coincide with the adsorption points at relative pressures of 0.8 and less, and at $p/p_s = 0$ an appreciable amount of adsorbed substance remains on the adsorbent. It is probable that in these cases not only physical adsorption occurs, but also chemisorption. The remaining isotherms are completely reversible over the whole of the p/p_s range investigated. The convexity of the isotherms in the region of unimolecular adsorption may be explained partially by some nonuniformity in the adsorbent (edges, apexes, and cracks) and partially by the repulsive forces between molecules of the adsorbed substance, which can exist only if the molecules are all oriented in the same way in the adsorption layer. In all of the adsorption isotherms, except that of water, the formation of a second layer becomes complete at a comparatively high relative pressure (about 0.75). This indicates that the adsorbed molecules of the first layer almost completely screen the field of the adsorbent, so that further adsorption approximates to ordinary condensation in character. This view is confirmed by the fact that in this region the heats of adsorption are approximately the same as the heats of condensation [2]. The steeper rise of the water isotherm and the completion of the second layer at a lower value of p/p_s is probably due to hydrogen bonding between the adsorbed molecules and the occurrence of a considerable amount of adsorption under the action of chemical forces. The sharp rises in the isotherms at relative pressures of greater than 0.8 may be explained by multimolecular adsorption and, at very high values of p/p_s, by capillary condensation at the points of contact between crystals.

TABLE 2

Adsorption of Methanol Vapor on Quartz at 20° (p_s = 93.86 mm)

a	$p/p_s \cdot 10^3$	a	$p/p_s \cdot 10^3$	a	$p/p_s \cdot 10^3$

There are numerous adsorption-isotherm equations in the literature, both empirical equations, and also equations based on various theoretical concepts. We attempted to apply some of these equations to our results. Very often, in the treatment of experimental data on adsorption, use is made of Harkins and Jura's equation [3], which is based on the analogy between the behavior of monolayers of macromolecular substances on water and that of adsorbed layers on a solid:

$$\log \frac{p}{p_s} = B - \frac{A}{a^2}, \quad (1)$$

in which B and A are constants, a is the adsorption, and p/p_s is the relative pressure. When experimental data are in accord with this equation, a plot of $1/a^2$ against $\log p/p_s$ should be a straight line, the slope of which is a function of the specific surface of the adsorbent: $s = k\sqrt{A}$, in which k is a coefficient dependent on the properties of the adsorbed substance, but not dependent on the properties of the adsorbent. Equation 1 describes our isotherms satisfactorily in the region of unimolecular coverage. However, experiment indicates that the value of k does depend on the adsorbent. Using the value of the specific surface of quartz found from the adsorption isotherm for nitrogen, we found that for quartz the adsorption of methanol is characterized by k = 0.164 sq. m per micromole, whereas for barium sulfate [4] k = 0.068 sq.m. per micromole, i.e., there is more than a twofold variation in k from one adsorbent to another.

Adsorption measurements on heptane and benzene at two different temperatures provided data for the calculation of differential heats of adsorption from the equation

$$Q_d = RT^2 \left(\frac{\partial \ln p}{\partial T}\right)_a \qquad (2)$$

The relationship between the differential heat of adsorption and the extent of adsorption is shown for benzene and heptane in Fig. 2. Each curve has a clearly defined maximum in the region of a complete unimolecular layer ($\Theta \approx 1$, Θ being the fractional unimolecular coverage), this being indicated on the curve by a_m. When adsorption increases beyond the unimolecular stage, the differential heat falls and approximates to the heat of condensation. The different courses taken by the curves in the unimolecular region indicate a substantial difference in the processes accompanying the sorption of these vapors. The fall in the differential heats of adsorption of benzene may result, firstly, from a certain nonuniformity of the quartz surface and, secondly, from the appreciable polarization of benzene in the adsorbed state, so that repulsive forces arise between the molecules, which are identically oriented induced dipoles. This view is indirectly confirmed by the definite solubility of benzene in water and therefore also the appreciable interaction of benzene molecules with the OH groups that cover the quartz surface. With further increase in the extent of adsorption, the distances between benzene molecules are reduced and short-range attractive forces begin to predominate. In this case the maximum on the differential heat curve should be at $\Theta = 1$. However, before the unimolecular layer is complete, some adsorption in the second layer apparently occurs. As the heat of adsorption in the second layer is less than that in the first owing to screening of the field of the adsorbent, the maximum on the curve $Q = f(a)$ is displaced to the left from the point a_m, a behavior that will be noted on both curves. Heptane, having an insignificant solubility in water, evidently forms considerably weaker bonds with water and therefore with the OH groups covering quartz than benzene does. Hence, at low adsorption

Fig. 1. Adsorption isotherms for vapors: 1) water; 2) methanol; 3) 1,2-dichloroethane; 4) benzene; 5) heptane (20° on quartz).

coverage the heat of adsorption may be less than the heat of condensation. The increase in the heat of adsorption, continuing until a unimolecular layer is completed, may be explained, as in the case of benzene, by an increase in the effect of attractive forces between adsorbed molecules as their concentration in the adsorbed layer increases. However, since the heptane molecule is nonpolar and is apparently not appreciably polarized in the adsorption field of the quartz surface, no repulsive forces arise between these molecules. It may be supposed that, in the adsorption of heptane on quartz, the first molecules adsorbed play the part of adsorption centers that are somewhat more active than the quartz surface itself.

The occurrence of maxima on Q = f(a) curves at θ = 1 has been observed by many investigators: by Orr [6] in a study of the adsorption of nitrogen and argon on crystals of potassium and cesium chlorides; by Rhodin [7] in an investigation of the adsorption of nitrogen and argon on monocrystals of copper and on a zinc surface; by Beebe and coworkers [8] in the course of direct measurements of the heats of adsorption of nitrogen and argon vapors on Graphon carbon black, distinct maxima at θ = 1 and θ = 2 being observed; and by Bering and Serpinsky [9] in an investigation of the adsorption of nitrogen vapor on sodium chloride crystals. The view that we have taken regarding the maxima on Q = f(a) curves is the same as that taken in the literature cited above. It must be stated that in our case the results of the calculation of differential heats of adsorption must be treated with some caution, since the temperature interval between the isotherms, especially the

Fig. 2. Differential heats of adsorption: 1) benzene; 2) heptane (on quartz).

benzene isotherms (5°), is not large enough to yield reliable data. This is particularly true for the region of low coverage.

The region of high adsorption is of no less interest. In particular, many researchers report the formation of very thick layers of adsorbed substance (up to 100 molecular layers and up to 1000 A) in the region of saturation [10-15]. Some theoretical papers have appeared [16-18] in which attempts are made to explain the formation of such thick adsorbed layers. On the other hand there have been investigations [19] in which no such formation of thick layers was observed. Using the value of a_m (extent of adsorption corresponding to the completion of a unimolecular layer) calculated by Brunauer, Emmett, and Teller's method, we

Fig. 3. Verification of the applicability of the equation for the multimolecular adsorption of vapors: 1) heptane; 2) benzene; 3) 1,2-dichloroethane; 4) methanol; 5) water (on quartz).

determined the number of layers formed in the adsorption of various substances on quartz (Table 6). It will be seen that in the region of saturation very thick adsorbed layers are not formed. It should be noted that these results, if incorrect, can only be too high, since it is assumed in the calculation that there is no capillary condensation at the places of contact between the particles.

Among theoretical papers devoted to the multimolecular region of adsorption, those of Halsey [20], Hill [21], and McMillan and Teller [22] deserve attention; they lead to the adsorption equation:

$$\ln \frac{p_s}{p} = \frac{k}{v^s} \qquad (3)$$

in which v is the number of adsorbed layers at pressure p; p_s is the saturated vapor pressure; and k is a proportionality constant determined by molecular forces. Halsey proposed a more general form of this equation, in which the power index 3 is replaced by the more general s. The physical basis of Equation 3 lies in the assumption that the potential of van der Waals forces between adsorbed atoms and the adsorbent falls off inversely as the cube of the distance. Experimental data obtained by Harkins and Jura [23] for the adsorption of nitrogen vapor on anatase (TiO_2 powder) are closely described by Equation 3 with a power index of 2.67 instead of 3. According to Drain and Morrison [24], $s = 2$ for the adsorption of argon on rutile. In a study of the adsorption of nitrogen, argon, and oxygen on aluminum foil, Bowers [25] obtained close accord with Equation 3 with a power index of approximately 3. We have verified the applicability of the equation of Frenkel, Halsey, and Hill to our data, but instead of the number of adsorbed layers we took the value of the adsorption, since in this way we could avoid the use of an uncertain value for the density of the substance in the adsorbed state, uncertain values for the surface of the adsorbent and for a_m, and the insufficiently valid assumption of the regular formation of layers of adsorbed substance on the adsorbent. When this is done, Equation 3 must be regarded rather as a semi-empirical equation than as a theoretical equation of the Frenkel-Halsey-Hill type.

Taking logarithms in Equation 3, we obtain a linear relationship between $\log \log p_s/p$ and $\log a$:

$$\log \log \frac{p_s}{p} = \log k - s \log a. \qquad (4)$$

Fig. 3 shows our experimental data expressed in these coordinates. It will be seen that the adsorption isotherms of heptane, benzene, and methanol are straight lines, so that Equation 4 is applicable. The applicability of the equation is somewhat less for 1,2-dichloroethane, and it is not applicable at all for water. It may be supposed that, in the case of water, the occurrence of hydrogen bonding results in the nonapplicability of Equation 4, and therefore also of Equation 3. The power index s calculated from the graph (Fig. 3) differs from 3 in all cases; for heptane it is 1.90, for benzene 2.06, for methanol 2.88, and for 1,2-dichloroethane 1.69, behavior that is in accord with the investigation of Bowers [26], who studied the thickness of saturated helium films on aluminum and obtained $s = 2.0 \pm 0.3$, and with those of Bering [27], who obtained $s = 2$ for the adsorption of methanol vapor on a mercury surface.

It is thus shown that Equation 4 is applicable in the region of multimolecular adsorption on nonporous adsorbents in the range of relative pressures of 0.65-0.97.

In conclusion I wish to express my deep indebtedness to M.M. Dubinin, B.P. Bering, and V.V. Serpinsky for their constant interest in this investigation.

SUMMARY

1. The adsorption of vapors of polar and nonpolar substances on crystalline quartz having a specific surface of 0.6 sq.m/g was investigated with the aid of a highly sensitive adsorption balance.

2. It was shown that the suggestion of Harkins and Jura to the effect that the coefficient k - which characterizes the compressibility of the adsorbed layer - is independent of the nature of the adsorbent surface is not in accordance with the experimental results.

3. On the curves for the differential heats of adsorption of benzene and heptane vapors, there are clearly defined maxima in the region of the point corresponding to the complete filling of a unimolecular layer.

4. In none of the investigated cases was the formation of a very thick adsorbed film observed. At a relative pressure of 0.9 the number of layers does not exceed 4-5, and at $p/p_s = 0.98$ the number of layers is 6-12.

5. The Frenkel-Halsey-Hill equation satisfactorily describes all of the isotherms (with the exception of that of water) in the middle region of multimolecular adsorption, but the power index must be given values of less than 3.

LIQUATION IN THE SYSTEM $ZrO_2 - SiO_2$

N.A. Toropov and F.Ya. Galakhov

The study of the systems containing zirconia is associated with the development of the manufacture of new kinds of silicate products, particularly refractories. The system zirconia-silica is of great importance, not only in itself, but also as the basis for the study of ternary silicate systems.

Zhirnova [1] was the first to determine the fusion diagram, and according to her results zircon $ZrSiO_4$ melts without decomposition and gives two eutectics: one with zirconia and one with silica. The fusion of zircon was described similarly in earlier papers [2], but the description was not confirmed in later investigations [3, 4] according to which zircon melts with decomposition and there is only one eutectic.

These contradictions made it desirable to make a further verification of the character of the fusion of zircon. In the course of this work the phenomenon of liquation was observed in the system, and this caused us to extend the investigation to a larger region of the system.

EXPERIMENTAL

Starting materials: zirconia, obtained by the calcination of zirconium nitrate and containing 0.35% SiO_2, 0.03% TiO_2, 0.16% Al_2O_3, and 0.06% Fe_2O_3, and powdered crystal quartz containing 99.90% SiO_2. Weighed amounts of the materials were mixed carefully in an agate mortar, moistened with a dextrin solution, compressed into the form of rods, and fused in an electric arc. The experiments were carried out in a microfurnace similar to that described previously [5]; the tungsten spiral was made from wire 0.8 mm in diameter, the internal diameter of the spiral was 5 mm, and the number of turns was 20. The spiral was protected by five tantalum screens and one external nickel screen. This arrangement enabled us to heat the samples to 2500° in oxygen-free argon. The temperature was measured with an optical pyrometer. The pyrometer was calibrated by the use of samples having known melting points: Al_2O_3 – 2050°, $MgO \cdot Al_2O_3$ – 2135°, La_2O_3 – 2316° and BeO – 2520°. The melting point was determined by observing the sample through the optical pyrometer, the temperature at which distinct melting occurred being recorded. The time taken in heating the sample from 1500° until it began to melt was 10-20 seconds, and the experiment was repeated three or four times, a new test sample being taken each time. Owing to the volatility of silica at high temperatures, all of the experiments had to be carried out very quickly with a minimum time of treatment.

No maximum for the compound $ZrSiO_4$ was found on the melting point curve. The examination of polished sections of samples differing in composition showed that only one crystalline phase separated, this being very prone to form dendrites or, occasionally, isometric grains (Fig. 1). The refractive index of the crystals, which was found to be greater than 2.05, indicated that they were zirconia. X-ray analysis of the crystals showed that they consisted of a solid solution of ZrO_2 in SiO_2, as found also in previous investigations [1, 3]. After being melted, all of the samples were opaque. In immersion preparations, a transparent glass was observed in samples containing not more than 20% of zirconia. As the zirconia content was increased, the glass became brown and more opalescent, and finally opaque.

Natural zircon crystals were also heated for 10-15 seconds at various temperatures and then examined in the form of polished sections. At 1800° glass and very fine crystals appeared. With rise in temperature the relative amount of glass increased and the dimensions of the newly formed crystals increased. It was found, unexpectedly, that two immiscible liquids were formed. A structure corresponding to this behavior was clearly observed in the sections. One liquid was dispersed in the other in the form of spherical or oval-shaped drops. A

Fig. 1. Zircon crystals (reflected light; magnification 450)

Fig. 3. Phase diagram of the system $ZrO_2 - SiO_2$ (according to the work of the authors and of Curtis and Sowman) S_s = solid solution.

photomicrograph of a section is shown in Fig. 2. The liquid that forms discrete droplets crystallizes, and very fine ZrO_2 crystals separate. The other liquid forms a turbid brown glass. It has thus been established that Barlett's suggestion [6] that two immiscible liquids may be formed in the system is correct. However, Barlett did not carry out any precise investigations in this direction.

Our further experiments had the object of defining the limits of the liquation field. The samples were heated until fully melted, cooled to the annealing temperature, at which they were kept for 5-30 seconds, and then pushed into the cold zone of the furnace with the aid of a magnet. Owing to its small dimensions, the sample cooled rapidly, particularly in the first stage of cooling. In order to determine the extent to which the composition of the sample changed on account of the vaporization of the silica under the experimental conditions, silica contents were determined on an unheated sample and on a sample heated for ten seconds at 2350°. The amount of material necessary for analysis was prepared by carrying out the heat treatment on numerous samples of identical composition. The silica content was determined from the loss in weight resulting from treatment with a mixture of hydrofluoric and sulfuric acids. In view of the fairly high purity of the starting materials, this indirect method for the determination of silica can be regarded as quite satisfactory. The original sample contained 55.60% of silica, and the heated sample also contained 55.60% of silica. The complete identity of the two results is of course fortuitous, but they indicate that silica volatilizes to a quite insignificant extent, this being attributable to the shortness of the period of heating. The products resulting from the heat treatment were examined microscopically in the form of sections. The results of the investigation are presented in the table.

TABLE

Results of the Determination of the Liquation Field in the System $ZrO_2 - SiO_2$

Sample No.	Composition (% by weight)		M.p. (°C)	Annealing temperature (°C)	Phases

7	30	70	2180		

Fig. 3 shows the phase diagram for the system $ZrO_2 - SiO_2$. That part of the diagram lying below 1800° is taken completely from Curtis and Sowman's paper [4]. The field of solid solutions was not investigated, and its limits are taken from the same paper. The liquation field is in the section from 41 to 42% by weight of SiO_2 (58.3-76.80 mole-%), and it begins at 2250° and has a critical point at 2430° (53% SiO_2).

In silicate systems the formation of two immiscible liquids has been observed most frequently when certain bivalent cations are present [7]. Liquation in a silicate melt in presence of a cation of higher valency (other than Zr^{4+}) is known only for Ti^{4+} [8]. According to the theoretical concepts developed for silicates by Esin [9], the occurrence of liquation is determined by the force of interaction between the metal cation and O^{2-}, and the greater the energy of interaction, the lower the silica content at which liquation begins. In the series of bivalent cations, with reduction in radius - and therefore with increase in the force of interaction with O^{2-} - the silica content at which liquation of the system begins also diminishes. The most powerful of the bivalent cations is Mg^{2+} (0.78 A). The Zr^{4+} cation, though of greater radius (0.87 A), should interact more strongly with oxygen ions because of its high charge, which is double that of the magnesium ion. Ti^{4+} is a still stronger cation (0.64 A). In the respective binary systems formed with these cations, liquation begins at silica contents of 60, 58.3, and 9.1 mole-% SiO_2. Thus, when we pass from bivalent to quadrivalent cations, we find that the same law holds with respect to the relationship between the strength of the cation and the beginning of liquation in the system.

SUMMARY

1. The system $ZrO_2 - SiO_2$ was investigated at 1800-2500°.
2. It was shown that zircon $ZrSiO_4$ melts with decomposition into zirconia and a liquid.

3. Liquation occurs in the system at high temperatures. The temperatures and concentrations at which the two liquids coexist were determined.

4. The high-temperature region of the phase diagram of the system $ZrO_2 - SiO_2$ was constructed.

EXCHANGE REACTIONS OF STEREOISOMERIC MERCURY DERIVATIVES OF STILBENE

A.N. Nesmeyanov, A.E. Borisov, and N.A. Volkenau

Continuing our investigation of the stereochemistry of electrophilic and radical exchange, we have now attempted to bring the stereoisomeric mercury derivatives of stilbene described in a previous communication [1] into exchange reaction with heavy-metal salts. It was found that mercury derivatives of stilbene, unlike the corresponding 2-chlorovinyl compounds [2], have little tendency to exchange their mercury atoms for atoms of other metals.

Cis- and trans-bis(1,2-diphenylvinyl)mercurys react with $TlCl_3$ as follows, without yielding organothallium compounds:

$$[C_6H_5CH{=}CC_6H_5]_2Hg + TlCl_3 \rightarrow C_6H_5CH{=}C(C_6H_5)HgCl + C_6H_5CH{=}C(C_6H_5)Cl + TlCl. \quad (1)$$

When treated with tin-sodium alloy, the stereoisomeric 1,2-diphenylvinylmercury chlorides are converted into the corresponding bis(1,2-diphenylvinyl)mercurys. Under severe conditions, trans-1,2-diphenylvinylmercury chloride yields also a little trans-stilbene.

Both in alcohol and also in absence of solvent (in the melt at 240-260°), trans-bis(1,2-diphenylvinyl)mercury fails to react with $SnCl_2$. When treated with $SnCl_2$ in alcohol, trans-1,2-diphenylvinylmercury chloride symmetrizes with formation of trans-bis(1,2-diphenylvinyl)mercury. In acetone both trans-1,2-diphenylvinylmercury chloride and trans-bis(1,2-diphenylvinyl)mercury react with $SnCl_2$ with formation of trans-stilbene, i.e. they react characteristically for organomercury compounds in which the radicals are at the left end of the series of relative electronegativeness [3].

Organotin compounds are obtained only when mercury derivatives of cis-stilbene are treated with $SnCl_2$ in acetone, but even then the reaction is not as smooth as usual [3]. At room temperature one of the products is bis(1,2-diphenylvinyl)tin dichloride, formed by Equation 2 (or 3):

$$[C_6H_5CH{=}CC_6H_5]_2Hg + SnCl_2 \rightarrow [C_6H_5CH{=}CC_6H_5]_2SnCl_2 + Hg \quad (2)$$

or

$$2C_6H_5CH{=}C(C_6H_5)HgCl + 2SnCl_2 \rightarrow [C_6H_5CH{=}CC_6H_5]_2SnCl_2 + SnCl_4 + 2Hg, \quad (3)$$

but this substance could not be isolated in the pure state as it was always mixed with 1,2-diphenylvinyltin trichloride and cis-stilbene. After hydrolysis with aqueous ammonia, however, it was possible to isolate α-stilbenestannonic acid and bis(1,2-diphenylvinyl)tin oxide. The first of these compounds is soluble in ether, chloroform, carbon tetrachloride, and benzene, but insoluble in alcohol and petroleum ether; it melts at 157-160°. The second compound is insoluble in organic solvents and is infusible. When the reaction with $SnCl_2$ is carried out at 70-80°, only 1,2-diphenylvinyltin trichloride (together with 20-30% of cis-stilbene) is formed.

It is probable that the exchange reaction is complicated by disproportionation. The isolation of 1,2-diphenylvinyltin trichloride from its mixture with liquid cis-stilbene is difficult and is accompanied by losses. In most of the experiments, therefore, the organotin trichloride was hydrolyzed to α-stilbenestannonic acid, which was then converted into 1,2-diphenylvinyltin trichloride by the action of $SOCl_2$ [4]. The analogous conversion of bis(1,2-diphenylvinyl)tin oxide into bis(1,2-diphenylvinyl) dichloride was not found to be possible, treatment with $SOCl_2$ resulting in the formation of only 1,2-diphenylvinyltin trichloride, which was obtained in low yield. The organotin compounds so obtained readily exchanged their tin atoms for mercury. Thus, with $HgCl_2$, 1,2-diphenylvinyltin trichloride gives cis-1,2-diphenylvinylmercury chloride, and with HgO α-stilbene-

stannonic acid and bis(1,2-diphenylvinyl)tin dichloride give cis-bis(1,2-diphenylvinyl)mercury. In an alcoholic medium, treatment of cis-1,2-diphenylvinylmercury chloride or cis-bis(1,2-diphenylvinyl)mercury with $SnCl_2$ gives cis-stilbene.

Although mercury derivatives of the stereoisomeric stilbenes do not readily exchange mercury for another metal, the transfer of a stilbene residue from one mercury atom to another is effected fairly easily. In the present investigation we have made a detailed study of such reactions. It was found that the desymmetrization of cis- and trans-bis(1,2-diphenylvinyl)mercurys by means of mercuric bromide gives the stereoisomeric 1,2-diphenylvinylmercury bromides, m.p. 118-120° and 157-158° respectively. As agents for the symmetrization of the stereoisomeric 1,2-diphenylvinylmercury halides, Na_2SnO_3 and NiI$_2$ can be used, as well as KI and C_4H_9Li [1].

With the object of investigating the stereochemistry of these reactions, we attempted to reconvert the organometallic compounds into the original α-bromostilbenes. We used dioxane dibromide as reagent [5]. The stereoisomeric mercury derivatives of stilbene were found to react with dioxane dibromide in accordance with Equations 4 and 5:

$$[C_6H_5CH = CC_6H_4]_2Hg + Br_2 \cdot O\langle\rangle O \rightarrow C_6H_5CH = C(C_6H_4)HgBr + $$

$$+ C_6H_5CH = C(C_6H_4)Br. \qquad (4)$$

$$C_6H_5CH = C(C_6H_4)HgX + Br_2 \cdot O\langle\rangle O \rightarrow C_6H_5CH = C(C_6H_4)Br + HgBrX. \qquad (5)$$

At room temperature, trans-bis(1,2-diphenylvinyl)mercury reacts mainly in accordance with Equation 4, with formation of 1,2-diphenylvinylmercury bromide, m.p. 157-158°, and trans-α-bromostilbene. After one hour at 70-80°, the trans isomers of bis(1,2-diphenylvinyl)mercury and 1,2-diphenylvinylmercury chloride, and also the high-melting 1,2-diphenylvinylmercury bromide, yield only $HgBr_2$ and trans-α-bromostilbene. Free bromine splits trans-bis(1,2-diphenylvinyl)mercury completely at room temperature. The mercury derivatives of cis-stilbene react with dioxane dibromide with formation of cis-α-bromostilbene and $HgBr_2$ already at room temperature. By this method it is possible to synthesize 1,2-diphenylvinylmercury bromide, m.p. 118-120°, only when strictly defined proportions of reactants are used. With dioxane dibromide the above-described 1,2-diphenylvinyltin trichloride, α-stilbenestannonic acid, and bis(1,2-diphenylvinyl)tin oxide yield cis-α-bromostilbene.

The reactions that we have carried out may be represented as follows (see also [1]):

All of these reactions are stereochemically pure, i.e. only one geometric isomer is obtained as product. The configurations of the stereoisomeric α-bromostilbenes are known [6, 7]. It will be seen from the scheme of reactions that, starting from trans-α-bromostilbene, we may carry out closed cycles of reactions consisting of two, three, or four links, and so return to the original trans-α-bromostilbene. Starting from cis-α-bromostilbene, we may carry out cycles having two, three, four, or five links, and again return to cis-α-bromostilbene. It is improbable that in all of these cycles inversion of the configuration occurs the exact number of times necessary for a return to the original form in each case. It is more probable that all of the compounds obtained from trans-α-bromostilbene have trans configurations, and all obtained from cis-α-bromostilbene have cis configurations. This conclusion is in accord with the tentative configurations assigned to the organomercury stereoisomers in a previous investigation [1]. As regards the compounds prepared in the present investigation, this conclusion enables us to assign cis configurations to the 1,2-diphenylvinylmercury bromide of m.p. 118-120°, the 1,2-diphenylvinyltin trichloride of m.p. 108-110°, and the α-stilbenestannonic acid of m.p. 157-160°. The trans configuration can be assigned to the 1,2-diphenylvinylmercury bromide of m.p. 157-158°.

The behavior observed in all of these reactions confirms the correctness of the rule relating to the preservation of geometric configuration in electrophilic and radical exchange reactions [2]. It is difficult to say why mercury derivatives of stilbene have such low reactivities, but it is very probable that the cause is to be found in steric difficulties. This view is confirmed by the fact that styrene derivatives of the type $C_6H_5CH = CHHgX$ [8] readily exchange a mercury atom for tin or thallium.

EXPERIMENTAL

1. Reaction of the Stereoisomeric Bis(1,2-diphenylvinyl)mercurys with Thallium Trichloride. A solution of 2.5 g (0.0080 mole) of $TlCl_3$ in 16.6 ml of ether was added to a solution of 4 g (0.0072 mole) of trans-bis(1,2-diphenylvinyl)mercury in 200 ml of anhydrous dioxane at 80°. The mixture was heated at 70-80° for one hour. The precipitate was then filtered off, washed with ether, and treated with boiling dioxane; it consisted of TlCl and weighed 1.85 g (97%). Suitable treatment of the combined dioxane solutions and repeated recrystallizations from alcohol yielded 2.7 g (91%) of trans-1,2-diphenylvinylmercury chloride, m.p. 140-141° (no depression in a mixture test) and 1.35 g (87%) of trans-α-chlorostilbene, m.p. 62-63.5° (the literature [9] gives 53-54°). Lowering of the reaction temperature resulted in incomplete decomposition of the original substance. The reaction does not go in ether owing to the low solubility of the original substance.

Under the same conditions, cis-bis(1,2-diphenylvinyl)mercury yield: 98% of TlCl and 91% of cis-1,2-diphenylvinylmercury chloride, m.p. 130-131°. In ether the course of the reaction is the same, but it is very slow and incomplete.

2. Reaction of the Stereoisomeric 1,2-Diphenylvinylmercury Chlorides with Tin-Sodium Alloy. a) trans-1,2-Diphenylvinylmercury Chloride. A mixture of 2 g (0.0048 mole) of trans-1,2-diphenylvinylmercury chloride, 6 g of a tin-sodium alloy (15% of sodium), and 20 ml of absolute xylene was boiled for three hours. The precipitate was then filtered off and treated with two portions of boiling xylene. The combined xylene filtrates yielded 1.05 g (77%) of trans-bis(1,2-diphenylvinyl)mercury, m.p. 238-241° after recrystallization from dioxane (no depression in a mixture test), and a very small amount of trans-stilbene, m.p. 122-123° after recrystallization from alcohol (no depression in a mixture test). It was found that, when the reaction was carried out in benzene, an eight-hour boil was necessary in order to attain a 70% yield of trans-bis(1,2-diphenylvinyl)mercury. In this case no trans-stilbene by-product was observed.

b) cis-1,2-Diphenylvinylmercury Chloride. A mixture of 3 g (0.0072 mole) of cis-1,2-diphenylvinylmercury chloride, 9 g of the tin-sodium alloy, and 60 ml of absolute benzene was boiled for three hours. The precipitate was filtered off and treated with two portions of boiling benzene. The combined benzene filtrates yielded 1.95 g (97%) of cis-bis(1,2-diphenylvinyl)mercury, m.p. 144-145° after recrystallization from a mixture of benzene and alcohol (no depression in a mixture test).

3. Reaction of trans-Bis(1,2-diphenylvinyl)mercury and of trans-1,2-Diphenylvinylmercury Chloride with Stannous Chloride. All experiments on the reaction of trans-bis(1,2-diphenylvinyl)mercury and of trans-1,2-diphenylvinylmercury chloride with $SnCl_2$ were carried out in sealed tubes. At the end of the period of heating, the tubes were opened and the precipitate of mercury or unchanged reactant was filtered off. Solvent was completely removed from the filtrate under reduced pressure, and the solid residue was crystallized from absolute alcohol. In those experiments (Nos. 3, 5, and 7 in Table 1) in which a mixture of trans-stilbene and trans-1,2-diphenylvinylmercury chloride was formed, the substance was dissolved in acetone and treated with an acetone solution of KI. The trans-1,2-diphenylvinylmercury chloride was then converted into trans-bis(1,2-diphenyl-

vinyl mercury, which was readily separated owing to its low solubility. Stilbene separated from the solution when acetone was distilled off. The results of the experiments are given in Table 1.

Reaction of trans-bis(1,2-diphenylvinyl) mercury with anhydrous $SnCl_2$ in absence of solvent (in the fused state) was also carried out in a sealed tube. When 1 g (0.0018 mole) of trans-bis(1,2-diphenylvinyl)mercury was heated with 0.5 g (0.0026 mole) of anhydrous stannous chloride at 240-260° for 10-15 minutes, 0.95 of the original substance was recovered unchanged (m.p. 242-243°). When heating was prolonged beyond 15 minutes, decomposition set in with separation of mercury, small amounts of trans-stilbene, and a resinous mass, free from metal.

TABLE 1

Expt. No.	Amount of			Temperature (°C)	Time (hrs)	Yield of trans isomer (g)		
	Mercury compound (g)	$SnCl_2$ (g)	Solvent (ml)			R*H	RHgCl	R_2Hg
			trans-bis(1,2-diphenylvinyl)mercury					
1	0.5	0.25	C_2H_5OH 20	100	9	–	–	0.45
2	0.5	0.25	C_2H_5OH 20	180	8	–	–	0.45

*R = ($C_6H_5CH = CC_6H_5$).

4. Reaction of cis-Bis(1,2-Diphenylvinyl)mercury and of cis-1,2-Diphenylvinylmercury Chloride with Stannous Chloride. All of the experiments were carried out in sealed tubes. At the end of the heating period the tubes were opened, the precipitate of mercury was filtered off (in all of the experiments the yield of mercury was almost quantitative), and solvent was removed under reduced pressure (all treatments were carried out at room temperature). The residue was extracted with benzene, and the benzene was removed. Also, in Experiments 1 and 5 (Table 2) the residue, which did not contain tin, was isomerized into trans-stilbene by means of iodine in chloroform in sunlight. In Experiments 2, 4, and 6 the residue was treated with excess of aqueous ammonia, and the precipitate that formed was filtered off; cis-stilbene was extracted from the residue with ether and isomerized into trans-stilbene, and, with the aid of chloroform, the residue was separated into soluble α-stilbenestannonic acid and insoluble bis(1,2-diphenylvinyl)tin oxide. In Experiments 3 and 7, 1,2-diphenylvinyltin trichloride was isolated directly from the residue by repeated recrystallization from heptane. The results of the experiments are given in Table 2.

1,2-Diphenylvinyl tin trichloride melts at 108-110°, is very soluble in benzene, chloroform, and carbon tetrachloride, and is of good solubility in ethanol, methanol, and heptane.

Found %: C 41.60; 41.63; H 2.78; 2.72; Cl 25.69; 25.68
$C_{14}H_{11}SnCl_3$. Calculated %: C 41.56; H 2.72; Cl 26.34

α-Stilbenestannonic acid melts at 157-160° (not sharp). It is readily soluble in chloroform, carbon tetrachloride, ether, and benzene, and is insoluble in alcohol and petroleum ether.

Found %: Sn 35.55; 35.63
$C_{28}H_{22}SnO_2$. Calculated %: Sn 35.87

Bis(1-2-diphenylvinyl)tin oxide does not melt, even above 300°; it is insoluble in organic solvents.

Found %: Sn 23.91; 23.85

$C_{28}H_{22}SnO$. Calculated %: Sn 24.07

*R = $(C_6H_5CH = CC_6H_5)$.

5. Reaction of α-Stilbenestannonic Acid and of Bis(1,2-diphenylvinyl)tin Oxide with Thionyl Chloride. A solution of 4.5 g (0.036 mole) of $SOCl_2$ in 25 ml of petroleum ether was added to a suspension of 3 g (0.009 mole) of α-stilbenestannonic acid in 10 ml of petroleum ether. The mixture was heated for 90 minutes at 60-70°. The petroleum ether and excess of $SOCl_2$ were then removed under reduced pressure. The product was 3.2 g (88%) of 1,2-diphenylvinyltin trichloride, m.p. 109-110° after recrystallization from heptane.

Under the same conditions, 2 g (0.004 mole) of bis(1,2-diphenylvinyl)tin oxide and 0.74 g (0.006 mole) of $SOCl_2$ in 20 ml of petroleum ether yielded 1.17 g of 1,2-diphenylvinyltin trichloride, m.p. 107-109.5° after recrystallization from heptane (the melting point was not depressed by admixture of the substance obtained from α-stilbenestannonic acid).

6. Hydrolysis of 1,2-Diphenylvinyltin Trichloride. Excess of aqueous ammonia was added to a solution of 3 g of 1,2-diphenylvinyltin trichloride in 20 ml of alcohol. The precipitate that formed was filtered off, dried, and recrystallized from a mixture of benzene and alcohol. The product was 2.35 g (97%) of α-stilbenestannonic acid, m.p. 158-160° (not sharp). A mixture test showed no depression.

7. Reaction of 1,2-Diphenylvinyltin Trichloride with Mercuric Chloride. Hot solutions of 1.5 g (0.0037 mole) of 1,2-diphenylvinyltin trichloride in 25 ml of alcohol and 1 g (0.0037 mole) of mercuric chloride in 5 ml of alcohol were mixed, and the mixture was boiled for 1-2 minutes and then set aside at room temperature for 12 hours. Alcohol was removed under reduced pressure. The residue was treated with boiling benzene, and the benzene was evaporated. The product, amounting to 1.35 g (87%), was cis-1,2-diphenylvinylmercury chloride, m.p. 129-130° after recrystallization from alcohol (no depression in a mixture test).

8. Reaction of α-Stilbenestannonic Acid and of Bis(1,2-Diphenylvinyl)tin Oxide with Mercuric Oxide. Boiling aqueous 5 N NaOH (100 ml) was added to a suspension of 2 g (0.0006 mole) of α-stilbenestannonic acid in

32 ml of alcohol, and to the resulting mixture a hot solution of 0.82 g (0.003 mole) of $HgCl_2$ in 24 ml of alcohol was added. The mixture was boiled for 1-2 minutes, and was then diluted with water. The precipitate was filtered off and dried. It was treated several times with boiling benzene, benzene was evaporated off, and the residue was recrystallized from a mixture of benzene and alcohol. The product, amounting to 1.5 g (89%) was cis-bis(1,2-diphenylvinyl)mercury, m.p. 145-146° (undepressed in a mixture test).

Under the same conditions, 1 g (0.002 mole) of bis(1,2-diphenylvinyl)tin oxide in 16 ml of ethanol, 50 ml of 5 N NaOH, and 0.55 g (0.002 mole) of $HgCl_2$ in 16 ml of alcohol yielded 0.76 g (67%) of cis-bis(1,2-diphenylvinyl)mercury.

9. Reaction of the Stereoisomeric Bis(1,2-diphenylvinyl)mercurys with Mercuric Bromide. A mixture of 3 g (0.0053 mole) of trans-bis(1,2-diphenylvinyl)mercury, 2.1 g (0.0058 mole) of $HgBr_2$, and 51 ml of absolute alcohol was heated in a sealed tube in a boiling water bath for 5.5 hours. The crystals that formed were filtered off, the filtrate was evaporated down, and the residue was treated with benzene. The substance remaining after evaporation of the benzene was added to the main bulk of the crystals, and the whole mass was crystallized twice from alcohol. The product, amounting to 4.8 g (98%) was 1,2-diphenylvinylmercury bromide, m.p. 157-158°. This substance is soluble in alcohol, benzene, and chloroform.

	Found %:	C 36.72; 36.89; H 2.43; 2.52
$C_{14}H_{11}HgBr$.	Calculated %:	C 36.58; H 2.39

Under the same conditions, 2 g (0.0035 mole) of cis-bis(1,2-diphenylvinyl)mercury and 1.35 g (0.0038 mole) of $HgBr_2$ in 34 ml of absolute alcohol yielded 4.85 g (95%) of 1,2-diphenylvinylmercury bromide, m.p. 118-120° after two crystallizations from alcohol. This substance is soluble in alcohol, benzene, and chloroform.

	Found %:	C 36.62; 36.74; H 2.52; 2.53
$C_{14}H_{11}HgBr$.	Calculated %:	C 36.58; H 2.39

10. Symmetrization of the Stereoisomeric 1,2-Diphenylvinylmercury Halides. a) Symmetrization of the Stereoisomeric 1,2-Diphenylvinylmercury Bromides with Potassium Iodide. A solution of 3.35 g (0.02 mole) of potassium iodide in 54 ml of acetone and 6.5 ml of water was added to a solution of 2 g (0.0021 mole) of the 1,2-diphenylvinylmercury bromide of m.p. 157-158° in 150 ml of acetone and 10 ml of water. The mixture stood at room temperature for one day. The precipitate was then filtered off and dried. The product, amounting to 1.2 g (93%), was trans-bis(1,2-diphenylvinyl)mercury, m.p. 239-241° after recrystallization from dioxane.

An experiment on the low-melting 1,2-diphenylvinylmercury bromide was carried out with the same amounts, but, owing to the appreciable solubility of cis-bis(1,2-diphenylvinyl) mercury in aqueous acetone, at the end of the reaction the reaction mixture was diluted with water and the precipitate filtered off. The substances obtained were cis-bis(1,2-diphenylvinyl)mercury, amounting to 0.65 g (53%) (m.p. 145-146° after recrystallization from a mixture of benzene and alcohol), and unchanged 1,2-diphenylvinylmercury bromide (m.p. 119-120°; 0.95 g, i.e. 7.5% of the amount taken).

b) Symmetrization with Sodium Stannite. A solution of Na_2SnO_2 (prepared from 3 g of $SnCl_2 \cdot 2H_2O$ and 7.5 g of NaOH in 75 ml of water) was added to a solution of 2.2 g of cis-1,2-diphenylvinylmercury chloride in 40 ml of alcohol. The mixture was set aside for 36 hours. The precipitate was then filtered off, dried, and carefully extracted with boiling benzene. The benzene was evaporated, and the residue, recrystallized from a mixture of benzene and alcohol, gave 1.2 g (95%) of cis-bis(1,2-diphenylvinyl)mercury, m.p. 145-147°.

Under the same conditions, the 1,2-diphenylvinylmercury bromide of m.p. 118-120° gave cis-bis(1,2-diphenylvinyl)mercury in 94% yield.

Trans-1,2-diphenylvinylmercury chloride and the 1,2-diphenylvinylmercury bromide of m.p. 157-158° were symmetrized with sodium stannite to the extent of 65-70%, the product being trans-bis(1,2-diphenylvinyl)-mercury.

c) Symmetrization with Ammonia. Ammonia gas was passed for two hours through a solution of 2 g of trans-1,2-diphenylvinylmercury chloride in 80 ml of chloroform. The solution was diluted with water, and the precipitate was filtered off, dried, and carefully extracted with boiling xylene. Xylene was removed under reduced pressure, and the residue was recrystallized from dioxane. The product, amounting to 0.8 g (59%), was trans-bis(1,2-diphenylvinyl)mercury, m.p. 240-241°. Under the same conditions, 1,2-diphenylvinylmercury

*R = ($C_6H_5CH = CC_6H_5$).

bromide of m.p. 157-158° gave trans-bis(1,2-diphenylvinyl)mercury in 60% yield. Cis-1,2-diphenylvinylmercury chloride and low-melting 1,2-diphenylvinylmercury bromide gave cis-bis(1,2-diphenylvinyl)mercury in 88% yield.

11. Reaction of Dioxane Dibromide with Organotin and Organomercury Derivatives of the Stereoisomeric Stilbenes. All of the experiments with dioxane dibromide were carried out in the same way. To a solution (or suspension) of the organometallic compound in dioxane (mercury compounds) or benzene (tin compounds), a dioxane solution of dioxane dibromide was added. When reaction was complete, solvent was removed under reduced pressure and the residue was treated with 3% HCl and ether. From the aqueous layer the metal sulfide was precipitated with H_2S (HgS was precipitated quantitatively, dried, and weighed). The stereoisomeric α-bromostilbenes - and in some experiments the stereoisomeric 1,2-diphenylvinylmercury bromides - were isolated from the ether layer. The α-bromostilbenes were extracted from the mixture with petroleum ether and were recrystallized from methanol cooled with solid carbon dioxide. The 1,2-diphenylvinylmercury bromides were recrystallized from alcohol. The results of the experiments are given in Table 3.

12. Reaction of trans-Bis(1,2-diphenylvinyl)mercury with Bromine. To a suspension of 2 g (0.0036 mole)

of trans-bis(1,2-diphenylvinyl)mercury in 70 ml of benzene, 1.15 g (0.0072 mole) of bromine was added at room temperature. The solution was decolorized immediately, and the precipitate disappeared. The mixture was set aside for 90 minutes, after which time it was treated with 3% HCl; the layers were separated. Hydrogen sulfide precipitated 0.82 g (38%) of HgS. From the benzene layer, 1.7 g (91%) of trans-α-bromostilbene, m.p. 30-32°, was isolated.

SUMMARY

1. By the reaction of cis-bis(1,2-diphenylvinyl)mercury and of cis-1,2-diphenylvinylmercury chloride with stannous chloride, cis-1,2-diphenylvinyltin trichloride, cis-α-stilbenestannonic acid, and cis-bis(1,2-diphenylvinyl)tin oxide were prepared.

2. By reaction of the stereoisomeric bis(1,2-diphenylvinyl)mercurys with mercuric bromide, the stereoisomeric 1,2-diphenylvinylmercury bromides were prepared.

3. It was shown that mercury derivatives of the stereoisomeric stilbenes do not give organothallium and organotin derivatives when treated with $TlCl_3$ and tin-sodium alloy, respectively. Trans-bis(1,2-diphenylvinyl)-mercury and trans-1,2-diphenylvinylmercury chloride do not give organotin compounds when treated with stannous chloride.

4. The reaction of mercury and tin derivatives of the stereoisomeric stilbenes with dioxane dibromide was investigated, and it was shown that it results in the formation of the stereoisomeric α-bromostilbenes.

5. The behavior of the metal derivatives of stilbene that we have studied is in accord with the rule relating to the preservation of geometric configuration in electrophilic and radical exchange reactions.

2-AMINOVINYL KETONES

COMMUNICATION 4. SYNTHESIS OF KETONES OF THE PYRIDINE SERIES

N.K. Kochetkov, Yanush Dombrovsky, A.V. Bazhenova, E.S. Severin,

and A.N. Nesmeyanov

2-Aminovinyl ketones are now readily accessible owing to the recent development in our laboratory of a method for their synthesis [1]. In the present paper we describe a new synthesis of ketones of the pyridine series based on the reaction between 2-aminovinyl ketones and 2-chlorovinyl ketones, which have been studied in our laboratory during recent years. These compounds react together without the aid of any condensing agent even at room temperature. In the case of 2-chlorovinyl methyl ketone and 2-aminovinyl methyl ketone, a substance corresponding in properties to 5-acetyl-2-methylpyridine can be isolated from the reaction mixture. The picrate and oxime of this substance were found to have the same constants as those cited in the literature. The yield of 5-acetyl-2-methylpyridine attained 50%. The reaction was found to be fairly general.

(1)

R = CH_3, C_2H_5, C_3H_7, C_5H_{11}

The best results were obtained under the following conditions. A mixture of the alkyl 2-chlorovinyl ketone and double the amount of the alkyl 2-aminovinyl ketone, without addition of solvent, was allowed to stand at room temperature. After a few hours precipitation began of the amine hydrochloride formed from the liberated hydrogen chloride, which was taken up by the excess of the 2-aminovinyl ketone. After several days precipitation ceased and, if considered necessary, the mixture was heated for a few hours in a water bath in order to complete the reaction. The reaction mixture was heated with dilute sulfuric acid in order to separate the pyridine derivative from other reaction products, and the pyridyl ketone was isolated from the acid solution by the usual method and was purified by distillation. By this method, starting from ethyl, propyl, and pentyl 2-aminovinyl ketones and the corresponding alkyl 2-chlorovinyl ketones, we prepared the corresponding 5-acyl-2-alkylpyridines in satisfactory yields.

As it is possible that the reaction between a 2-aminovinyl ketone and a 2-chlorovinyl ketone may proceed in a different direction with formation of a 3-acyl-4-alkylpyridine in accordance with the equation

(2)

The structure of the compounds obtained was in need of confirmation. We therefore submitted one of these compounds – ethylpropionylpyridine – to permanganate oxidation, which should yield either isocinchomeronic or cinchomeronic acid, depending on which of the two possible structures is correct. The acid obtained, which was

isolated from the oxidation products in 54% yield, corresponded in properties to isocinchomeronic acid, and, in final confirmation of its identity, its dimethyl ester was prepared and found to be a solid melting at 162° (dimethyl cinchomeronate is a liquid). It was thus established that the compounds that we had prepared were 5--acyl-2-alkylpyridines and that the reaction proceeds in accordance with the first scheme.

The reaction investigated is of interest from the preparative point of view, for reported methods for the synthesis of ketones of the pyridine series, particularly alkylpyridyl ketones, have not been adequately developed [2]. Our reaction is similar in character to that described by Benary for the synthesis of ketones of the pyridine series by the action of ammonia on hydroxymethylene ketones [3-5]. Benary's reaction has not been developed sufficiently to be regarded as a satisfactory method of synthesis, for the author gives no precise details of the yields of products and in some cases does not give their constants; moreover, it is known that by-products are formed in this reaction. The method that we have proposed has also the indisputable advantage that the original 2-chlorovinyl and 2-aminovinyl ketones are readily accessible; furthermore, their structures do not need special proof, whereas it is generally necessary to prove the structure of the hydroxymethylene ketone in each separate case and such structures have been the subject of dispute until quite recently (see, for example [6]).

The fact that 2,5- and not 3,4-substituted pyridines are formed in our reaction enables us to make some suggestions regarding the course of the reaction. It should be noted the reaction is similar to the condensation carried out earlier in our laboratory between 2-chlorovinyl ketones and 3-aminocrotonic ester, which yielded 2,6-dialkylnicotinic acids [7]. Since 2-aminovinyl ketones, being α,β-unsaturated β-amino compounds, are similar in character and behavior to 3-aminocrotonic ester, it is quite to be expected that the result will be the same in both the cases that we have studied: the alkyl radical and oxygen function will be in the 2,5-positions of the pyridine nucleus formed. It is well known that both derivatives of 3-aminocrotonic ester [8] and derivatives of 2-aminovinyl ketones [9] are alkylated with transfer of the reaction center to the α-carbon atom. It may be considered that, in our case also, the 2-aminovinyl ketone is first "ketovinylated" at the α-carbon atom, and the resulting derivative of an unsaturated δ-diketone undergoes redistribution of bonds and ring closure with formation of the energetically more favorable aromatic pyridine system. This view is expressed in the scheme:

An analogous scheme can be given for the condensation of 2-chlorovinyl ketones with 3-aminocrotonic ester, referred to above [7].

We have studied one example of the condensation of 2-aminovinyl ketones with β-keto acetals, which are readily accessible, being prepared from 2-chlorovinyl ketones [10]. It was found that the condensation of 2-aminovinyl methyl ketone with acetoacetaldehyde dimethyl acetal again yielded 5-acetyl-2-methylpyridine, identical with the substance prepared by the method described above.

This reaction, however, requires considerably more severe conditions (heating a mixture of the reactants for many hours at 135°), and the yield of pyridyl ketone is lower. As this reaction is inferior to the one already described as a preparative method, this variant of the synthesis was not developed further. The great difference in the condensation conditions between chlorovinyl ketones and β-keto acetals makes it impossible to make any suggestions regarding the course of the second reaction.

EXPERIMENTAL

5-Acetyl-2-methylpyridine. A mixture of 14.3 g (0.137 mole) of 2-chlorovinyl methyl ketone and 23.3 g (0.274 mole; 100% excess) of 2-aminovinyl methyl ketone was allowed to stand for two days at room tempera-

ture. The thick dark-colored reaction mixture was then boiled for 5 minutes with excess of 20% sulfuric acid, cooled, and extracted three times with ether. The aqueous layer was made alkaline with 40% aqueous caustic soda and extracted with ether; the extract was dried over potassium carbonate. The ether was distilled off, and the residue was vacuum-distilled, a fraction boiling at 95-97° (5 mm) being collected. The yield was 9.4 g (50.8%). After redistillation the 5-acetyl-2-methylpyridine had the following constants: b.p. 95-96° (5 mm); n_D^{20} 1.5319; d_4^{20} 1.0681.

Found %: C 70.76; 70.91; H 6.82; 6.76
C_8H_9ON. Calculated %: C 71.08; H 6.73

For 5-acetyl-2-methylpyridine the literature [3] gives b.p. 231-232°.

The oxime was prepared by heating the substance for two hours with hydroxylamine in aqueous alcohol; colorless needles, m.p. 183° (from 40% alcohol).

Found %: N 18.58; 18.85
$C_8H_{10}ON_2$. Calculated %: N 18.66

The literature [3] gives m.p. 182°.

The picrate was prepared in alcoholic solution; yellow crystals, m.p. 190° (from alcohol).

The literature [3] gives m.p. 190°.

2-Ethyl-5-propionylpyridine. This was prepared similarly from 9.3 g (0.078 mole) of 2-chlorovinyl ethyl ketone and 15.4 g (0.156 mole) of 2-aminovinyl ethyl ketone. Reaction was allowed to proceed for three days. The mixture was treated as indicated above. In the vacuum distillation the fraction boiling at 115-115° (8 mm) was collected, the yield being 10.2 g (80%). After redistillation the 2-ethyl-5-propionylpyridine had the following constants: b.p. 113-115° (7 mm); n_D^{20} 1.5160; d_4^{20} 1.0200.

Found %: C 73.07; 72.86; H 7.98; 8.09
$C_{10}H_{13}ON$. Calculated %: C 73.00; H 7.98

For 2-ethyl-5-propionylpyridine the literature [4] gives b.p. 247-248°.

The oxime was prepared as before; colorless needles, m.p. 102.5° (from 40% alcohol).

Found %: N 16.00; 15.83
$C_{10}H_{14}ON_2$. Calculated %: N 15.73

The literature [4] gives m.p. 104°.

5-Butyryl-2-propylpyridine. This was prepared similarly from 26.4 g (0.20 mole) of 2-chlorovinyl propyl ketone and 46 g (0.40 mole) of 2-aminovinyl propyl ketone. Reaction was allowed to proceed for seven days. The mixture was treated as before, and in the vacuum distillation the fraction boiling at 133-134° (8 mm) was collected, the yield being 15.5 g (41%). After redistillation the 5-butyryl-2-propylpyridine had the following constants: b.p. 134-135° (8 mm); n_D^{20} 1.5117; d_4^{20} 0.9877.

Found %: C 75.21; 75.07; H 8.72; 8.80
$C_{12}H_{17}ON$. Calculated %: C 75.35; H 8.96

For 5-butyryl-2-propylpyridine the literature [5] gives b.p. 152° (13 mm); d_4^{20} 0.9782.

The oxime was prepared as before; colorless needles, m.p. 88.5° (from 40% alcohol).

Found %: N 13.79; 13.95
$C_{12}H_{18}ON_2$. Calculated %: N 13.60

The literature [5] gives m.p. 84-86°.

5-Hexanoyl-2-pentylpyridine. This was prepared similarly from 6.8 g (0.042 mole) of 2-chlorovinyl pentyl ketone and 11.9 g (0.085 mole) of 2-aminovinyl pentyl ketone. Reaction was allowed to proceed for seven days. The mixture was boiled with 90 ml of dilute hydrochloric acid (1:5). Further treatment was as before, and in the vacuum distillation the fraction boiling at 183-184° (6 mm) was collected, the yield being 1.9 g (18.3%) (when reaction was allowed to proceed for only three days, the yield was 14%). After redistillation the 5-hexanoyl-2-pen-

tylpyridine had the following constants: b.p. 158-159° (3 mm); n_D^{20} 1.5010; d_4^{20} 0.9464.

Found %: C 77.54; 77.42; H 10.39; 10.32
$C_{10}H_{13}ON$. Calculated %: C 77.73; H 10.16

Reaction of 2-Chlorovinyl Methyl Ketone with Acetoacetaldehyde Dimethyl Acetal. A mixture of 25.5 g (0.20 mole) of acetoacetaldehyde dimethyl acetal and 24.7 g (0.29 mole) of 2-chlorovinyl methyl ketone was heated at 135° for 70 hours. When cool, the reaction mixture was extracted with ether, and the ether extract was dried over potassium carbonate. The ether was distilled off, and the residue was vacuum-distilled, the fraction boiling at 103-106° (7 mm) being collected. The yield was 8.6 g (31.5%). After redistillation the 5-acetyl-2-methylpyridine had the following constants: b.p. 85-85.5° (3 mm); n_D^{20} 1.5320; d_4^{20} 1.0664.

The oxime was prepared in the usual way: m.p. 182°, undepressed by admixture with the oxime of 5-acetyl-2-methylpyridine prepared from 2-aminovinyl methyl ketone.

The picrate was prepared in the usual way: m.p. 190°, undepressed by admixture with the picrate of 5-acetyl-2-methylpyridine prepared from 2-aminovinyl methyl ketone.

Oxidation of 2-Ethyl-5-propionylpyridine. Potassium permanganate (51.4 g) was added to a mixture of 6.13 g of 2-ethyl-5-propionylpyridine and 600 ml of water. The mixture was heated at 70° for two hours and was then boiled until decolorized. Manganese dioxide was filtered off and treated with boiling water. The combined filtrates were evaporated down to 200 ml. Concentrated hydrochloric acid (50 ml) was added to the hot solution, and the mixture was allowed to stand in a refrigerator for three days. The precipitate of acid was filtered off and dried at 90° (10 mm). The yield was 3.3 g (54%); m.p. 243°.

As the melting point data in the literature are very inconsistent and as there are indications [11] that the pure acid cannot be prepared by recrystallization, we converted our sample into the dimethyl ester. A mixture of 2.5 g of the acid, 48.6 ml of absolute methanol, and 2 ml of concentrated sulfuric acid was boiled for three hours. When the mixture was cooled, a precipitate formed and was filtered off and washed with methanol. Recrystallization from absolute methanol gave colorless needles, m.p. 162°. For dimethyl isocinchomeronate the literature [11] gives m.p. 164°.

SUMMARY

1. The reaction of alkyl 2-aminovinyl ketones with alkyl 2-chlorovinyl ketones was investigated. It provides a method for the synthesis of 5-acyl-2-alkylpyridines.

2. The structure of the products was confirmed by the oxidation of one of them to isocinchomeronic acid.

3. It was shown that the condensation of 2-aminovinyl methyl ketone with acetoacetaldehyde dimethyl acetal yields 5-acetyl-2-methylpyridine.

SEPARATION OF AMINO CARBOXYLIC ACIDS FROM AMMONIUM CHLORIDE WITH THE AID OF CATION - EXCHANGE RESINS

E.I. Vasilyeva and R.Kh. Freidlina

In the ammonolysis of chloro carboxylic acids, the corresponding amino acids are formed in admixture with ammonium chloride. As is well known, when the amino carboxylic acid and ammonium chloride have very similar solubilities in the solvents generally used for their separation (methanol, diethylamine, etc.), the separation is effected by treatment of the mixture with excess of lead oxide or silver oxide. This method is very laborious and is not always successful.

In recent years, increasing application has been found for ion-exchange resins for the isolation and separation of mixtures of amino carboxylic acids [1]. There is very little information in the literature regarding the isolation of amino carboxylic acids from their hydrochlorides and the separation of amino carboxylic acids from ammonium chloride with the aid of ion-exchange resins. We may here mention papers describing the use of anionites for the isolation of alanine [2] and ε-aminohexanoic acid [3] from their pure hydrochlorides or from the hydrochloride in admixture with ammonium chloride [2].

As far as we know, the separation of amino carboxylic acids from ammonium chloride with the aid of cation-exchange resins has not been described. The use of sulfocationites for this purpose appeared to us to be particularly attractive in view of the ready availability of various cation-exchange resins of this type having high capacity, mechanical strength, chemical stability, and other necessary qualities. It is known that sulfocationites can bind amino acids fairly firmly, so that it should be possible to separate amino acids from admixed acid and neutral substances simply by elution of the column with water after the solution containing the amino acid has been passed through.

By the use of the cationites SBS and SDV-3*, which contain sulfo groups, we succeeded in separating glycine, norvaline, 7-aminoheptanoic acid, and 9-aminononanoic acid from admixed ammonium chloride. We isolated these amino acids both from equimolecular mixtures of amino acid and ammonium chloride, and also from the reaction mixtures obtained by the ammonolysis of the corresponding chloro carboxylic acids with aqueous ammonia. In the second case the content of amino acid in the reaction mixture was determined in an aliquot by the van Slyke method. It was shown also that it is possible to isolate free 7-aminoheptanoic acid from its hydrochloride with the aid of the same cationites.

EXPERIMENTAL

Most of the experiments were carried out in columns containing 35-40 g of air-dry resin. The height of the column in a tube of diameter 2 cm was 35-40 cm. The loading and operation of the column were carried out in the usual way [4]. We studied the capacity of the cationite SBS both with respect to 7-aminoheptanoic acid, and also with respect to ammonium chloride. The dynamic capacity with respect to ammonium chloride was determined by titration of hydrochloric acid in the effluent.

It was found to be convenient to follow the course of the absorption and desorption of 7-aminoheptanoic acid by its qualitative reaction with ninhydrin, which is applicable to ω-amino as well as α-amino carboxylic acids. The amount of amino acid bound by the cationite was determined by washing the cationite with 5% am-

*All of the resins that we have examined were kindly provided by I.P. Losev, E.B. Trostyanskaya, and A.S. Tevlina, to whom we express our sincere thanks.

monia to bring about the desorption of the amino acid and then evaporating the eluate. The capacity with respect to 7-aminoheptanoic acid was found to be 125 mg per gram of resin for the passage of a 6% solution at 2 ml/min.sq.cm. The capacity with respect to ammonium chloride was found to be 50 mg per gram of resin for the passage of a 3% solution at 2-7 ml/min.sq.cm.

Fig. 1. Yield curves for: 1) glycine; 2) 7-aminoheptanoic acid; 3) norvaline; 4) 9-aminononanoic acid.

Fig. 2. Yield curves for 7-aminoheptanoic acid on the cationites: 1) SDV-1; 2) MSF; 3) SBSR; 4) SBS; 5) RF.

Using mixtures of 7-aminoheptanoic acid and ammonium chloride, we studied the effect of concentration and rate of passage on the dynamic capacity of the resin with respect to amino acid, and also the effect of the rate of passage and of the concentration of ammonia on the completeness of the removal of amino acid. The mixture to be separated contained 70% of 7-aminoheptanoic acid and 30% of ammonium chloride(Table 1).

These experiments showed that increase in the ammonia concentration from 5% to 10% did not reduce the volume of solution required for elution (Experiments 1 and 3) and that it was best to elute at a linear rate of passage of 1-1.5 ml/min.sq.cm. (Experiments 2, 5, and 6), but increase in the rate of passage to greater than 1.5-2 ml/min.sq.cm causes the amount of the amino acid passing into the effluent to increase (Experiments 2, 3, and 4).

Fig. 1 shows the yield curves for glycine, norvaline, 7-aminoheptanoic acid, and 9-aminononanoic acid on the cationite SDV-3. It will be seen that the acid that is most readily desorbed by ammonia is glycine (Curve 1), and the most difficultly desorbed acid is 9-aminononanoic acid (Curve 4). It will be seen also that in the first half of the whole volume of the eluate there is 75-90% of the total amount of amino acid to be eluted.

Fig. 2 presents the yield curves for 7-aminoheptanoic acid on the cationites SBS, SBSR, SDV-1, MSF, and RF. Some data characterizing these cationites have been reported in the literature [5-8]. It will be seen from Fig. 2 that the amino acid is most readily desorbed from SDV-1, and is most difficultly desorbed from RF.

Capacities with respect to 7-aminoheptanoic acid were determined for these cationites, and the results are shown in Table 2. The best results were obtained for the cationite SDV-1.

Some experiments on the purification of amino acids from ammonium chloride were carried out on a larger scale, and these showed that the results obtained in large columns were in accord with those obtained in 40-g columns. It was found that in the large columns the amount of 5% ammonia required for the complete desorption of the amino acids was very much less, since the dilute eluates could be used again in the following elution cycle. The results obtained are compared in Table 3, which shows that the proposed method for the separation of amino acids from ammonium chloride is applicable both to α-amino acids (Experiments 1 and 2) and to ω-amino acids (Experiments 3-5). In all cases the amino acids were recovered in 95-99% yield and they did not contain chlorine (Experiments 1-5). The isolation of amino acids from the reaction mixture obtained in the ammonolysis of the corresponding chloro carboxylic acids was also very satisfactory (Experiments 3-5).

From Table 3 it will be seen also that cationites containing sulfo groups are able to absorb amino acids from their hydrochlorides (Experiment 6). Thus, by passing pure 7-aminoheptanoic acid hydrochloride through the cationite SBS, 7-aminoheptanoic acid was obtained in 96% yield, and the resulting preparation was completely free from chloride ions.

TABLE 1

Expt. No.	Amount of mixture (g)	Concentration of mixture (%)	Linear rate of passage (ml/min. sq.cm)	Amount leaving column (g)	Concentration of aqueous NH_3 (%)	Linear rate of passage (ml/ min. sq.cm)*	Volume of eluate (ml)	Amount of amino acid obtained (g)**	Capacity with respect to amino acid (mg/g resin)
1	4.8	10	1.5-2	—	10	1-1.5	350	2.86	71
2	6	10	1.5	0.40	10	4	425	3.37	84
3	6	10	3	0.77	5	1-1.5	335	3.13	78
4	6	10	8	1.62	5	1-1.5	325	2.60	82
5	6	15	1.5-2	0.37	5	1-1.5	375	3.80	95
6	2	5	1.5-2	0.10	5	1.5	220	1.26	97

*Experiments 1-5 were carried out in a column containing 40 g of resin. In Experiment 6 the column contained 13 g of resin.
**The acid obtained melted at 183-184°, and the original acid at 186-187°.

TABLE 2

Cationite	Amount of resin (g)	Amount of mixture* (g)	Concentration of mixture (%)	Amount leaving column (g)	Volume of eluate** (ml)	Amount of amino acid obtained (g)	Capacity with respect to amino acid (mg/g resin)
MSF	40	8	10	0.04	150	5.53	138
SDV-1	38	8	10	—	100	5.55	158
SBSR	35	5.8	10	1.0	200	3.24	92
SBS	30	4.5	10	—	200	3.11	103
RF	6	2.5	10	0.65	140	1.0	62

*The mixture contained 70% of amino acid and 30% of ammonium chloride. The solution of the mixture was passed through the cationite at a rate of 1.5-2 ml/min.sq.cm.
**Elution was carried out at a rate of 1-1.5 ml/min.sq.cm.

TABLE 3*

Expt. No.	Cationite	Amount of mixture (g)	Amount of amino acid in mixture (g)	Amino Acid	Overall concentration of solution (%)	Rate of elution (ml/min)	Volume of eluate (ml)	Amt. of amino acid (g)	Amt. of amino acid (%)

6***	SBS	—	4	7-Aminoheptanoic acid	7	4-5	200	3.87	96.7

*The table gives the mean results of several duplicate experiments.
**In these experiments the amino acids were obtained by ammonolysis of the corresponding chloro carboxylic acids. The content of ω-amino acid in the solution was determined by the Van Slyke method.
***Isolation of the amino acid from the pure hydrochloride.

SUMMARY

1. A method is proposed for the separation of a mixture of an amino acid and ammonium chloride with the aid of cation-exchange resins.

2. It is shown that some amino carboxylic acids can be isolated from their hydrochlorides with the aid of cation-exchange resins.

3. It is shown that the Soviet cationites SBS, SBSR, and SDV can be successfully applied for the separation of amino carboxylic acids from ammonium chloride.

ADDITION OF MERCURY SALTS TO VINYL ETHERS

PREPARATION OF MERCURATED ACYLALS*

I.F. Lutsenko, R.M. Khomutov, and L.V. Eliseeva

The addition reaction of mercury salts in aqueous solution with substances containing an ethylene bond has been extensively investigated; the reaction results in the addition of a hydroxyl group and a residue of the mercury salt at the position originally occupied by the double bond. In this way olefins yield alcohols containing the residue of the mercury salt in the β-position [1]. When the medium is an alcohol [2] or amine [3] instead of water, the addition product contains an OR or NR_2 group instead of OH. The addition of mercury salts to olefins can be carried out also in a medium of aliphatic carboxylic acid [4]. In this case the double bond takes up a residue of the mercury salt and the acyloxy group corresponding to the acid used as medium.

A common feature of all of these reactions is the active participation of the solvent. The product always contains a residue of the solvent molecule (– OH, – OR, – NR_2, RCOO–) in its molecule. As regards the mechanism of the addition of mercury salts to ethylene bonds, on the basis of kinetic investigations it is generally considered that addition is preceded by reaction between the mercury salt and the solvent [5,6]. For reaction in an aqueous medium, therefore, the whole process can be represented as follows:

$$HgX_2 + H_2O \rightleftharpoons Hg\begin{matrix}X\\OH\end{matrix} + HX;$$

$$Hg\begin{matrix}X\\OH\end{matrix} + RCH = CH_2 \rightleftharpoons RCH(OH)CH_2HgX.$$

In a study of the addition of mercuric acetate to cyclohexene and styrene in dioxane, Wright [6] attempted to break down the addition reactions into its stages with the object of isolating intermediate products of the type $RCHXCH_2HgX$ and studying their hydrolysis (or alcoholysis), but no definite results were obtained. This type of direct addition of mercury salts without participation of the solvent is well known for compounds containing triple bonds and has been studied for hydrocarbons [7,8], alcohols [9], and ketones [10] of the acetylene series.

In view of the high reactivity of vinylethers, we considered that it would be possible to effect the addition of mercury salts to these compounds without the participation of the solvent, and so synthesize compounds of the type $XHgCH_2CH(OR)X$. Our experiments showed that mercuric acetate does indeed add rapidly at the double bond of a vinyl ether (methyl, ethyl, isopropyl, butyl, or phenylvinyl ether) as follows:

$$CH_2 = CHOR + (CH_3COO)_2Hg \rightarrow CH_2COOHgCH_2\begin{matrix}OR\\OCOCH_3\end{matrix}$$

By this reaction we have synthesized organomercury compounds of a new type - mercurated acylals - in almost quantitative yields. The reactions of methyl and ethyl vinyl ethers with mercuric acetate were carried out in

*Communication from Academician A.N. Nesmeyanov's Laboratory.

an absolute ether medium, the reaction with phenyl vinyl ether in absolute acetone, while the reactions of isopropyl and butyl vinyl ethers were carried out in absence of solvent. The mercurated acylals obtained from methyl, ethyl, and phenyl vinyl ethers are crystalline solids, and those obtained from the other two vinyl ethers are viscous oils. All of the compounds are rather unstable; they are readily hydrolyzed in the air, and they decompose within a few days when kept in a desiccator. When dissolved in water they are rapidly hydrolyzed to mercurated acetaldehyde.

The behavior of mercurated acylals towards certain reagents is interesting (for example, towards sodium iodide, triethyl phosphite, acetyl chloride, and caustic alkali). Under the action of these compounds mercurated acylals readily break down into the original reactants - the mercury salt and the vinyl ether. When mercurated acylals are treated with sodium iodide, the following reaction occurs:

$$CH_3COOHgCH_2CH(OR)OCOCH_3 + 4NaI \rightarrow CH_2 = CHOR + Na_2[HgI_4] + 2CH_3COONa.$$

The original vinyl ether is formed also when a mercurated acylal is treated with triethyl phosphite, and in addition, mercury and ethyl acetate are formed. The reaction can be represented as follows:

$$CH_3COOHgCH_2CH(OR)OCOCH_3 + P(OC_2H_5)_3 \rightarrow$$

$$\rightarrow CH_2 = CHOR + Hg + \left[\begin{matrix} CH_3COO & & OC_2H_5 \\ & P & \\ CH_3COO & & OC_2H_5 \end{matrix}\right] \downarrow$$

$$2CH_3COOC_2H_5 + (C_2H_5OPO_2)_x$$

Thus, we have a case here of alkylation by means of triethyl phosphite. A reaction carried out separately between mercuric acetate and triethyl phosphite also yielded ethyl acetate.

Under the action of acetyl chloride, mercurated acylals readily decompose as follows:

$$CH_3COOHgCH_2CH(OR)OCOCH_3 + CH_3COCl \rightarrow (CH_3CO)_2O + CH_2 = CHOR + CH_3COOHgCl.$$

The mercury salt that forms brings about the polymerization of the vinyl ether. If two molecular proportions of acetyl chloride are brought into reaction in one portion, instantaneous resinification of the liberated vinyl ether occurs.

When any of the mercurated acylals apart from that obtained from phenyl vinyl ether is treated with caustic alkali, mercuric oxide is precipitated.

Thus, none of this series of reactions, in which the mercurated acylal is readily decomposed into the original reactants - the vinyl ether and the mercury salt - and so behaves as a typical complex compound, permits the question of the structure of the compounds to be resolved unequivocally. A decisive reaction for determining whether the mercurated acylals are addition products of mercury salt and vinyl ether or are complexes was found in the bromination reaction.

If the mercurated acylals are complexes of the type $(CH_3COO)_2Hg \cdot CH_2 = CHOR$, then bromination should give the known dibromides of vinyl ethers:

$$(CH_3COO)_2Hg \cdot CH_2 = CHOR + Br_2 \rightarrow BrCH_2CH(OR)Br + (CH_3COO)_2Hg.$$

If, however, they are not complexes, but products of the addition of mercury salts to the double bonds of vinyl ethers, then bromination should result in the formation of bromicated acylals:

$$CH_3 \cdot COOHgCH_2CH(OR)OCOCH_3 + Br_2 \rightarrow BrCH_2CH(OR)OCOCH_3 + CH_3COOHgBr.$$

When the bromination of the mercurated acylals was carried out, it was found that the products were not dibromides of vinyl ethers, but bromo acylals. Bromo acylals are rather unstable compounds, which decompose rapidly when kept or when heated slightly.

The general chemical behavior of mercurated acylals enables us to conclude that we have here a new example of the phenomenon, extensively studied in recent times, of dual reactivity in organic compounds arising from the σ-conjugation of bonds [11].

EXPERIMENTAL

Preparation of the Acetic Ester of Acetoxymercuriacetaldehyde Ethyl Hemiacetal. A mixture of 3.2 g (0.01 mole) of mercuric acetate and 10 ml of absolute ether was cooled, and 0.72 g (0.01 mole) of ethyl vinyl ether was added. The mercuric acetate dissolved rapidly. When the reaction mixture was cooled with ice and salt, the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal, m.p. 38-39° (from ether), was precipitated. The yield was 3.6 g (92.3%).

Found %: C 24.28; 23.94; H 3.78; 3.64; Hg 51.90; 51.89
$CH_3COOHgCH_2CH(OC_2H_5)OCOCH_3$. Calculated %: C 24.61; H 3.59; Hg 51.44

Preparation of the Acetic Ester of Acetoxymercuriacetaldehyde Methyl Hemiacetal. A mixture of 6.4 g (0.02 mole) of mercuric acetate and 20 ml of absolute ether was cooled with ice and salt, and 4 ml of methyl vinyl ether was added. The yield of the acetic ester of acetoxymercuriacetaldehyde methyl hemiacetal was 7 g (91.7%); m.p. 48-49° (from acetone).

Found %: Hg 53.84
$CH_3COOHgCH_2CH(OCH_3)OCOCH_3$. Calculated %: Hg 53.28

Preparation of the Acetic Esters of Acetoxymercuriacetaldehyde Isopropyl and Butyl Hemiacetals. Isopropyl vinyl ether (0.86 g, i.e. 0.01 mole) was added with cooling to 3.2 g (0.01 mole) of mercuric acetate. The resulting oil was exposed to a vacuum for one hour to remove traces of isopropyl vinyl ether. The yield of the acetic ester of acetoxymercuriacetaldehyde isopropyl hemiacetal was 4 g (quantitative).

Found %: Hg 49.63; 49.75
$CH_3COOHgCH_2CH(OC_3H_7)OCOCH_3$. Calculated %: Hg 49.60

In a similar way, reaction of mercuric acetate with butyl vinyl ether gave a quantitative yield of the acetic ester of acetoxymercuriacetaldehyde butyl hemiacetal.

Found %: Hg 48.19; 48.40
$CH_3COOHgCH_2CH(OC_4H_9)OCOCH_3$. Calculated %: Hg 47.92

Preparation of the Acetic Ester of Acetoxymercuriacetaldehyde Phenyl Hemiacetal. To a cooled suspension of 3.2 g (0.01 mole) of mercuric acetate in 10 ml of dry acetone, 1.2 g (0.01 mole) of phenyl vinyl ether was added. When dissolution of the mercury salt was complete, the reaction mixture was cooled with ice and salt. The crystals of the acetic ester of acetoxymercuriacetaldehyde phenyl hemiacetal were filtered off; yield 4 g (93.1%); m.p. 96-97° (from ether).

Found %: Hg 45.95; 46.07
$CH_3COOHgCH_2CH(OC_6H_5)OCOCH_3$. Calculated %: Hg 45.73

Hydrolysis of the Acetic Ester of Acetoxymercuriacetaldehyde Ethyl Hemiacetal. A solution of 0.75 g (0.01 mole) of potassium chloride in 5 ml of water was added to a solution of 3.9 g (0.01 mole) of the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal in 10 ml of water. The crystals of chloromercuriacetaldehyde were filtered off; yield 2.8 g (quantitative); m.p. 128-129° (from water). There was no depression in a mixture melting point test with chloromercuriacetaldehyde prepared from ethyl vinyl ether.

Found %: Hg 71.95; 72.22
$CHgCH_2CHO$. Calculated %: Hg 71.88

Reaction of the Acetic Ester of Acetoxymercuriacetaldehyde Ethyl Hemiacetal with Sodium Iodide. A mixture of 36 g (0.24 mole) of sodium iodide and 100 ml of dry cyclohexanone was cooled with ice and salt, and a solution of 23.4 g (0.06 mole) of the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal in 15 ml of dry cyclohexanone was added. The mixture immediately became very thick. A fraction of boiling point 35-36°, amounting to 2.1 g (48.6%), was distilled from the reaction mixture on a water bath. The product (ethyl vinyl ether) had the following constants: b.p. 35-36°; n_D^{20} 1.3775; d_4^{20} 0.7545; found MR 21.97; calculated MR 21.85.

The literature [12] gives b.p. 36-36.1°; n_D^{20} 1.3779; d_4^{20} 0.7531. The ethyl vinyl ether obtained in this reaction was converted quantitatively into chloromercuriacetaldehyde [13].

Reaction of the Acetic Ester of Acetoxymercuriacetaldehyde Ethyl Hemiacetal with Acetyl Chloride. Acetyl chloride (2.2 ml, i.e. 0.03 mole) was added cautiously to a solution of 12 g (0.03 mole) of the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal in 10 ml of absolute ether. The reaction mixture became noticeably warm. Ether was distilled off from a water bath. Vacuum distillation gave a fraction of b.p. 35-36° (10 mm), which was found to be acetic anhydride; yield 1.7 g (56.6%). A light-brown viscous mass remained in the distillation flask (ethyl vinyl ether polymer). After being redistilled, the acetic anhydride had the following constants: b.p. 36° (10 mm); n_D^{20} 1.3895; d_4^{20} 1.0779; found MR 22.43; calculated MR 22.34. The acetic anhydride was converted into acetanilide.

Reaction of the Acetic Ester of Acetoxymercuriacetaldehyde Ethyl Hemiacetal with Triethyl Phosphite. Triethyl phosphite (11.7 g, i.e. 0.07 mole) was added to the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal (27.3 g, i.e. 0.07 mole). The reaction mixture became appreciably warm, and mercury separated immediately. The mixture was distilled from a water bath. The first fraction, b.p. 35-36°, was ethyl vinyl ether, obtained in 70% yield (3.5 g); n_D^{20} 1.3782; d_4^{20} 0.7564; found MR 21.98; calculated MR 21.85. A second fraction, b.p. 75-78°, yielded ethyl acetate in 86.0% yield (8.2 g); b.p. 76-77°; n_D^{20} 1.3733; d_4^{20} 0.9016; found MR 22.25; calculated MR 22.32. The literature [14] gives: b.p. 77.1°; n_D^{20} 1.3728; d_4^{20} 0.901.

Reaction of Triethyl Phosphite with Mercuric Acetate. To 16 g (0.05 mole) of mercuric acetate, 8.3 g (0.05 mole) of triethyl phosphite was added. Mercury separated rapidly, and the reaction mixture became very hot. When reaction was complete, a fraction boiling at 74-78° was distilled off; yield 4.8 g (54.5%). Redistillation yielded ethyl acetate having the following constants: b.p. 76-77°; n_4^{20} 1.3735 d_4^{20} ..8974; found MR 22.33; calculated MR 22.32.

Bromination of Mercurated Acylals. A solution of 2.5 ml (0.05 mole) of bromine in 10 ml of dry carbon tetrachloride was slowly added dropwise to a cooled (ice and salt) stirred solution of 19.5 g (0.05 mole) of the acetic ester of acetoxymercuriacetaldehyde ethyl hemiacetal in 50 ml of carbon tetrachloride. When the whole of the bromine had been added, the mixture was stirred for a few minutes further. The precipitate was filtered off and washed with dry carbon tetrachloride. Solvent was distilled from the filtrate, and the residue was distilled under reduced pressure. The acetic ester of bromoacetaldehyde ethyl hemiacetal came over at 77-79° (15 mm), the yield being 5.7 g (54%); it had n_D^{20} 1.4415; d_4^{20} 1.3610; found MR 40.38; calculated MR 40.97.

Found %: C 34.10; H 5.45

$BrCH_2CH(OC_2H_5)OCOCH_3$. Calculated %: C 34.12; H 5.21

The bromination of 40.4 g (0.1 mole) of the acetic ester of acetoxymercuriacetaldehyde isopropyl hemiacetal was carried out under similar conditions and gave 12.5 g (55.8%) of the acetic ester of bromoacetaldehyde isopropyl hemiacetal, b.p. 58° (5 mm); n_D^{20} 1.4457; d_4^{20} 1.3240; found MR 45.31; calculated MR 45.58.

Found %: C 37.29; 37.96; H 5.82; 6.09

$BrCH_2CH(OC_3H_7)OCOCH_3$. Calculated %: C 37.35; H 5.82

The bromination of 41.6 g (0.01 mole) of the acetic ester of acetoxymercuriacetaldehyde butyl hemiacetal yielded the acetic ester of bromoacetaldehyde butyl hemiacetal in 43.5% yield (10.4 g); this had b.p. 69-72° (5 mm); n_D^{20} 1.4445; d_4^{20} 1.2872; found MR 49.38; calculated MR 50.02.

Found %: C 40.11; 40.30; H 6.40; 6.44

$BrCH_2CH(OC_4H_9)OCOCH_3$. Calculated %: C 40.18; H 6.32

SUMMARY

1. By the addition of mercuric acetate to vinyl ethers, mercurated acylals of the following general formula were prepared:

R = CH_3, C_2H_5, i-C_3H_7, C_4H_9, C_5H_9.

2. By an investigation of the chemical behavior of the mercurated acylals it was established that they

have dual reactivity.

3. Bromo acylals of the following formula were synthesized:

R = C_2H_5, i-C_3H_7, C_4H_9.

PROPERTIES AND REACTIONS OF ALKYL AND ARYL PROPYLENE PHOSPHITES

COMMUNICATION 1. ADDITION REACTIONS

A.E. Arbuzov and N.A. Razumova

Cyclic phosphorous esters were first synthesized and studied by A.E. Arbuzov and Zoroastrova in 1945 [1]. Later, similar compounds were studied by A.E. Arbuzov in collaboration with Rizpolozhensky [2] and Azanovskaya [3]. Some investigations in this direction were carried out by Kabachnik and Rossiiskaya [4]. Lucas and coworkers [5] prepared some esters of propylene hydrogen phosphite. The study of these cyclic esters by A.E. Arbuzov and coworkers has shown that the cyclic phosphorous esters are in many respects similar in properties to open-chain phosphorous esters, but they show differences in certain properties [1,2].

In order to make a further study of the reactions of cyclic phosphorous esters, we prepared some alkyl and aryl propylene phosphites, of which some have already been reported in the literature and some were synthesized for the first time. These esters are of formula

R = CH_3; C_2H_5; n-C_3H_7; i-C_3H_7; n-C_4H_9; i-C_4H_9; n-C_5H_{11}; n-C_7H_{15}; n-C_9H_{19}; C_6H_5.

Esters of propylene hydrogen phosphite were first prepared by Lucas and coworkers [5]; Lucas did not study their reactions. The constants of some of our esters were identical with the values found by Lucas. The last four compounds were synthesized by us for the first time, and their constants are given in Table 1.

The esters were prepared either by the action of alkyl phosphorodichloridites on 1,2-propanediol or by the action of an alcohol on propylene phosphorochloridite in presence of pyridine. Propylene phosphorochloridite was converted also into propylene hydrogen phosphite, the constants of which are given in Table 1 since this substance was not characterized by Lucas.

One of the characteristic reactions of compounds containing tervalent phosphorus is the addition of sulfur. It was found that sulfur adds to alkyl propylene phosphites with evolution of heat. Thus, in the addition of sulfur to 8 g of methyl propylene phosphite, the temperature rose from 18° to 206°. With increase in the size of the alkyl radical, the addition reaction becomes less vigorous and the rise in temperature is reduced correspondingly.

By addition of sulfur to alkyl propylene phosphites, some mixed esters of phosphorothionic acid were obtained. Their constants are given in Table 2.

These phosphorothionic esters are colorless liquids. The methyl compound has an unpleasant thiol odor, but with increase in the size of the alkyl radical the odor becomes more feeble, and the hexyl compound is almost odorless.

A similar reaction - the addition of selenium - was carried out with ethyl propylene phosphite. Although the addition of selenium proceeds with evolution of heat, the selenium did not all react even when the mixture was heated to 130°. When the product was distilled in a high vacuum, it decomposed almost completely with separation of selenium.

A very small amount of an analytically pure mixed ester of phosphoroselenonic acid of the following formula was obtained:

 b.p. 107° (0.25 mm); n_D^{20} 1.4923

It was found that cuprous salts readily add to esters of propylene hydrogen phosphite with evolution of much heat, but no crystalline products were isolated. Some interesting reactions of these esters will be described in our second communication.

EXPERIMENTAL

Synthesis of Hexyl Propylene Phosphite

A mixture of 36.5 g of hexyl alcohol, 22 g of pyridine, and 1000 ml of absolute ether was prepared in a two-liter three-necked flask fitted with stirrer, dropping funnel, thermometer, and reflux condenser protected by a calcium chloride tube. The contents of the flask were vigorously stirred and cooled externally with snow and salt, and 50 g of propylene phosphorochloridite was added at such a rate that the temperature in the flask did not rise above −5°. When the whole of the acid chloride had been added, cooling was discontinued, but stirring was continued for 90 minutes at room temperature. The precipitate of pyridine hydrochloride was filtered off through a Nutsch filter and was washed 3-4 times on the filter with dry ether. After removal of ether the residue was vacuum-fractionated. Two fractionations (firstly with a Widmer column, and then from an Arbuzov flask) resulted in the isolation of the required hexyl ester, b.p. 109.5-111° (15 mm), in 19% yield (14 g); d_4^0 1.0369; d_4^{20} 1.0190; n_D^{20} 1.4465; found MR 54.00; calculated MR 54.62.

Found % P 15.03; 14.96

$C_9H_{19}O_3P$. Calculated % P 15.05

This ester is a colorless liquid of characteristic odor. It is sparingly soluble in organic solvents.

TABLE 8

Formula of substance	B.p. in °C (p in mm)	d_4^{20}	n_D^{20}	Analysis for P (%) calculated	found
	130-138 (2.5)	1.3001	1.4930	18.45	18.36 18.38
	102-104 (0.5)	1.2072	1.4762	17.03	17.14 17.02
	99-101 (0.2)	1.1221	1.4662	15.88	15.82 16.00
	86.5-88 (0.12)	1.1232	1.4705	14.76	14.63 14.50
	118.5-119 (0.15)	1.0891	1.4725	13.83	12.95 13.16

Synthesis of Heptyl Propylene Phosphite

The same procedure was used in the preparation of heptyl propylene phosphite. Reaction between 57.1 g of the acid chloride, 47.1 g of heptyl alcohol, and 32.1 g of pyridine in 800 ml of ether yielded 27 g (29%) of the heptyl ester, b.p. 130-132° (16 mm).

Found %: P 14.09; 13.83

$C_{10}H_{21}O_3P$. Calculated %: P 14.09

The heptyl ester is a colorless liquid of characteristic odor. It is sparingly soluble in organic solvents.

Synthesis of Octyl Propylene Phosphite

A similar procedure was used. Reaction was between 74 g of propylene phosphorochloridite, 89 g of octyl alcohol, and 42 g of pyridine in 800 ml of dry ether. Two fractionations with a Widmer column resulted in the isolation of 51 g (43%) of octyl propylene phosphite, b.p. 134-135° (10 mm); d_4^{20} 1.0031; d_4^{20} 0.9858; n_D^{20} 1.4470.

Found %: P 13.47; 13.23

$C_{11}H_{23}O_3P$. Calculated %: P 13.25

This ester is a colorless liquid having a feeble, but unpleasant odor. It is sparingly soluble in organic solvents.

Synthesis of Phenyl Propylene Phosphite

Under similar conditions, 40.65 g of 1,2-propanediol reacted with the corresponding amount of phenyl phosphorodichloridite in presence of pyridine and yielded, after vacuum fractionation, 54 g (52%) of phenyl propylene phosphite, b.p. 121-121.5° (11 mm).

Found %: P 15.60; 15.75

$C_9H_{11}O_3P$. Calculated %: P 15.66

This ester is a colorless liquid of feeble odor. It is soluble in organic solvents.

Preparation of Propylene Hydrogen Phosphite

Propylene phosphorochloridite (22 g) was placed in an Arbuzov flask fitted with a dropping funnel. The flask was cooled with snow and ice at −20°. The calculated amount of water (2.82 g) was added very cautiously from the dropping funnel. The reaction was very violent at first, but later became quieter. By the end of the reaction the liquid had become very viscous. The hydrogen chloride formed in the reaction was removed with a vacuum pump. Two fractionations from the Arbuzov flask yielded 15.5 g (86%) of propylene hydrogen phosphite, b.p. 96.5-97.5° (1 mm). Owing to the high viscosity of the substance, its density was not determined; it had n_D^{20} 1.4705.

Found %: P 25.03; 25.04

$C_3H_7O_3P$. Calculated %: P 25.40

The acid ester is a very hygroscopic thick colorless liquid. It is readily soluble in water, alcohol, benzene, and toluene, and it is sparingly soluble in carbon tetrachloride, ether, and dichloroethane.

Reaction of Sulfur with Methyl Propylene Phosphite

A mixture of 8.1 g of methyl propylene phosphite and 1.9 g of sulfur was prepared in a round-bottomed two-necked flask fitted with thermometer and reflux condenser protected from moisture with a calcium chloride tube. The temperature in the flask was maintained at 40° for 3-4 minutes, but it then began to rise rapidly, attaining 205°. The liquid remained clear, but acquired a bright-yellow color; the whole of the sulfur dissolved. Two fractionations from an Arbuzov flask yielded O-methyl O,O-propylene phosphorothioate in 18% yield (1.8 g); it had b.p. 136-138° (2.5 mm); d_4^{20} 1.3182; d_4^{20} 1.3001; n_D^{20} 1.4930; found MR 37.56; calculated MR 37.47.

Found %: P 18.36; 18.35

$C_4H_9O_2PS$. Calculated %: P 18.45

This substance is a colorless mobile liquid having a powerful thiol odor. It is vigorously oxidized by concentrated nitric acid. It is sparingly soluble in organic solvents.

By the method described sulfur-addition products were prepared from ethyl, propyl, isobutyl, and hexyl propylene phosphites (Table 2).

Reaction of Selenium with Ethyl Propylene Phosphite

By reaction of 10.7 g of ethyl propylene phosphite with 5.9 g of selenium, a very small amount of O-ethyl O,O-propylene phosphorselenoate was obtained (0.7 g, i.e. 4.7%); it had b.p. 107° (0.125 mm); n_D^{20} 1.4923. It is a clear colorless liquid having a very unpleasant odor. When the substance is stored, the red modification of selenium separates.

Found %: P 13.72; 13.85

$C_5H_{11}O_3PSe$. Calculated %: P 13.54

SUMMARY

1. Some previously undescribed alkyl and aryl propylene phosphites have been synthesized.

2. It has been shown that alkyl propylene phosphites give addition reactions with sulfur, selenium, and cuprous halides.

3. Previously undescribed O-alkyl O-propylene phosphorothioates have been synthesized.

O,O- AND O,S-DIALKYL ALKYLPHOSPHONOTHIOATES

M.I. Kabachnik, T.A. Mastryukova, and N.I. Kurochkin

In a study of the properties of O,O-dialkyl hydrogen phosphorothioites, Kabachnik and Mastryukova [1] found that, when treated with alkyl halides, their sodium derivatives enter into a reaction similar to the well known reaction of Michaelis and Becker [2] with formation of O,O-dialkyl alkylphosphonothioates:

In the examples of the reaction studied, sodium O,O-diethyl phosphorothioite was alkylated with ethyl iodide, ethyl chloride, benzyl chloride, and ethyl chloroacetate.

The structure of the resulting alkylphosphonothioic esters was proved by hydrolyzing them to the corresponding alkylphosphonic acids. Alkylphosphonothioic esters have been prepared also by other investigators. Thus, Pudovik and Zametaeva [3] prepared O,O-dialkyl alkylphosphonothioates containing electronegative substituents in the p-alkyl by addition of O,O-dialkyl hydrogen phosphorothioites to suitable unsaturated compounds. Arbuzov and Rizpolozhensky [4] and Razumov, Mukhacheva, and Sim-Do-Ken [5] prepared some O,O--dialkyl alkylphosphonothioates by addition of sulfur to alkylphosphonous esters and by reaction of alkylphosphonous dichlorides with sulfur and subsequent conversion of the alkylphosphonothioic dichloride into the ester. Finally, Pudovik and Kavyrzina [6] have recently made use of our method for the synthesis of O,O-dialkyl alkylphosphonothioates, and starting from O,O-dibutyl hydrogen phosphorothioite they have prepared some O,O--dibutyl alkylphosphonothioates.

Of all the proposed methods for the synthesis of O,O-esters of simple alkylphosphonothioic acids, the most general and convenient from the preparative point of view is the synthesis that we have described, which is based on a reaction of the Michaelis-Becker type. In our paper we showed also that O,O-diethyl ethylphosphonothioate is able to undergo isomerization; when this ester is heated at 140-150° with ethyl iodide in a sealed tube for three hours, an isomeric ester is formed, and the product has a higher boiling point, density, and refractive index than the original ester. As is well known, such a change in physical constants is characteristic for the Pishchimuka rearrangement. We therefore concluded that a rearrangement of this type occurs when a phosphonothionic ester is heated with an alkyl halide:

At that time we did not carry out a more rigorous proof of the structure of the ester obtained. In the present investigation we synthesized various O,O-dialkyl alkylphosphonothioates by the method described by us previously. In all cases the reaction gave the required product in satisfactory yields, ranging from 25% to 65%. The constants of the resulting esters are given in Table 1.

All of the phosphonothionic esters so obtained were subjected to the Pishchimuka rearrangement, for

which purpose they were heated with the corresponding alkyl bromides in sealed tubes at 140-200° for 4-10 hours. The higher the molecular weight of the ester, the more severe were the conditions required for reaction. The resulting phosphonthiolic esters were found to be colorless liquids of characteristic odor. Table 2 gives the physical constants of the phosphonothiolic esters (O,S-dialkyl alkylphosphonothioates) that we prepared.

*The upper figures refer to substances obtained by isomerization, and the lower figures to substances obtained from the phosphonic dichloride.

In order to prove the structure of the isomerization products, we took O,S-diethyl methyl- and ethyl-phosphonothioates as examples. We synthesized these substances by a method that left no doubt regarding their structure, namely by reaction between methylphosphonic dichloride, ethanol, and ethanethiol:

The properties and constants of the substances prepared by the two methods were practically identical (Table 3).

Moreover, the infrared spectra of the isomeric diethyl and dibutyl alkylphosphonothioates (Nos. 1-7 and Nos. 8-14) show quite clearly that the first are thionic isomers, and the second thiolic isomers (the presence of an intense absorption band in the region of 1215 cm^{-1} in the spectra of the latter is characteristic for substances containing a P=O linkage [7]).

EXPERIMENTAL

Preparation of O,O-Dialkyl Alkylphosphonothioates

The O,O-dialkyl hydrogen phosphorothiolte was converted into its sodium derivative by treatment with the calculated amount of sodium ethoxide, and the alkyl halide was then added dropwise with cooling. The reaction mixture was stirred at 70-80° for 2-3 hours, when the reaction mixture was found to be only weakly alkaline. The resulting sodium halide, which formed in a colloidal condition, was coagulated by adding a few drops of water and then heating the mixture. The sodium halide was filtered off, and the filtrate was dried over sodium sulfate. Benzene and alcohol were distilled off, and the residue was vacuum-distilled. Yields of 25-65% were obtained.

O,O-Diethyl Methylphosphonothioate. This was prepared from 15.4 g (0.1 mole) of O,O-diethyl hydrogen phosphorothiolte, sodium ethoxide prepared from 2.25 g (0.1 mole) of sodium and 4.5 g (0.1 mole) of dry ethanol, and 14.5 g (0.1 mole) of methyl iodide. The product, obtained in 42% yield (6.8 g) had b.p. 76.5-78° (13 mm); n_D^{18} 1.4610; d_4^{20} 1.0553; found MR 43.73, calculated MR 43.84.

Found %: C 36.28; 36.23; H 8.14; 8.05; P 18.68; 18.34
$C_5H_{13}O_2PS$. Calculated %: C 35.70; H 7.79; P 18.42

O,O-Diethyl Ethylphosphonothioate. This was prepared from 20 g (0.13 mole) of O,O-diethyl hydrogen phosphorothiolte, 8.8 g (0.13 mole) of sodium ethoxide, and 15 g (0.14 mole) of ethyl bromide. The product, amounting to 11.4 g (46%), had b.p. 80-83° (10 mm); n_D^{20} 1.4576; d_4^{20} 1.0324*.

O,O-Diethyl Propylphosphonothioate. This was prepared from 20 g (0.13 mole) of O,O-diethyl hydrogen phosphorothiolte, sodium ethoxide prepared from 3.0 g (0.13 mole) of sodium and 6.0 g (0.13 mole) of dry ethanol, and 16.0 g (0.13 mole) of propyl bromide. The product, amounting to 6 g (24%), had b.p. 63.5-65.5° (2 mm); n_D^{19} 1.4590; d_4^{20} 1.0158; found MR 52.86; calculated MR 52.88.

*The literature gives b.p. 90-93.5° (13 mm); n_D^{20} 1.4545; d_4^{20} 1.0324.

O,O-Dibutyl Ethylphosphonothioate. This was prepared from 39 g (0.18 mole) of O,O-dibutyl hydrogen phosphorothioite, 6.2 g (0.18 mole) of sodium ethoxide, and 20.5 g (0.19 mole) of ethyl bromide. It was obtained in 65% yield (28 g) and had b.p. 79.5-83° (2 mm); n_D^{20} 1.4533; d_4^{20} 0.9775; found MR 65.94; calculated MR 66.74°.

Preparation of O,S-Dialkyl Alkylphosphonothioates

O,S-Dialkyl alkylphosphonothioates were prepared by the isomerization of O,O-dialkyl alkylphosphonothioates in presence of excess of alkyl halide in sealed tubes. The temperature and duration of heating, depending on the identity of the original ester, ranged from 140° to 200° and from 4 to 11 hours, respectively. When cool, the tube was opened, and its contents were transferred to a Claisen flask. Excess of alkyl halide and other readily volatile substances were distilled from the solution, and the residue was vacuum-distilled.

O,S-Diethyl Methylphosphonothioate. This was prepared from 5.4 g (0.03 mole) of O,O-diethyl methylphosphonothioate, which was heated at 140-150° for 10 hours with 10 g (0.09 mole) of ethyl bromide. It was obtained in 31% yield (1.7 g) and had b.p. 106-108.5° (18 mm); n_D^{20} 1.4718; d_4^{20} 1.0904; found MR 43.18; calculated MR 43.35.

Synthesis of O,S-Diethyl Methylphosphonothioate

Dry ethanol (7.0 g, i.e. 0.15 mole) was added to a cooled mixture of 20 g (0.15 mole) of methylphosphonic dichloride, 19.4 g (0.16 mole) of dimethylaniline, and 150 ml of absolute ether. The reaction mixture was stirred at room temperature for three hours. The precipitate of dimethylaniline hydrochloride was then filtered off, and the filtrate was dried over calcined sodium sulfate. An ethereal solution of the ethyl methylphosphonochloridate so obtained was added to sodium mercaptide prepared from 6.2 g (0.1 mole) of ethanethiol and 2.3 g (0.1 mole) of sodium in 50 ml of dry ether. The reaction mixture became slightly warm. When the addition was complete, the mixture was set aside at room temperature for two days. The reaction mixture was treated with water, the ether layer was separated, and the aqueous layer was extracted with ether. The ether extracts were combined and dried over calcined sodium sulfate. After removal of ether and two vacuum distillations, 1.8 g of O,S-diethyl methylphosphonothioate was obtained; it had b.p. 110-111° (22 mm); d_4^{20} 1.0940; n_D^{18} 1.4743.

O,S-Diethyl Ethylphosphonothioate. This ester was prepared in a similar way from 24.6 g (0.16 mole) of ethylphosphonic dichloride; b.p. 64° (2 mm); d_4^{20} 1.0717; n_D^{18} 1.4721; yield 12.8 g (64%).

SUMMARY

1. Some O,O-dialkyl alkylphosphonothioates were prepared by a reaction of the Michaelis-Becker type.

2. It was found that when these esters were heated with alkyl halides to 140-200° Pishchimuka rearrangement occurred with formation of the isomeric O,S-dialkyl alkylphosphonothioates.

ACETYLENE DERIVATIVES

COMMUNICATION 173. CYANOETHYLATION OF ACETYLENIC ALCOHOLS

I.N. Nazarov and G.A. Shvekhgeimer

In previous papers [1] we have described the cyanoethylation of various acetylenic alcohols and glycols. Continuing this work, we have now studied the reaction of acrylonitrile with other secondary and tertiary acetylenic alcohols. The cyanoethylation reaction was carried out under comparable conditions at 20-30° for 20-24 hours, the catalyst being a 40% aqueous solution of potassium hydroxide.

The secondary acetylenic alcohols - ethynylmethylmethanol (3-butyn-2-ol) and ethylethynylmethanol (1-pentyn-3-ol) - reacted very vigorously with acrylonitrile, being converted into the corresponding 2-cyanoethyl ethers (I) in 80-90% yield:

(I)

R = CH_3, C_2H_5

In the series of tertiary acetylenic alcohols, increase in the size of a straight-chain radical has no appreciable effect on the cyanoethylation reaction, the corresponding 2-cyanoethyl ethers (II) being obtained in more than 90% yield:

(II)

R = n-C_3H_7, n-C_5H_{11}, n-C_9H_{17}

In the cyanoethylation of diethylethynylmethanol (3-ethyl-1-pentyn-3-ol), the 2-cyanoethyl ether (III) was obtained in 94% yield:

(III)

The cyanoethylation of tertiary acetylenic alcohols having branched chains was considerably more difficult. For example, in the cyanoethylation of ethynyldiisopropylmethanol (3-isopropyl-4-methyl-1-pentyn-3-ol), the 2-cyanoethyl ether (IV) was obtained in a yield of 97% on the amount of alcohol that reacted, but two-thirds of the acetylenic alcohol taken was recovered unchanged:

(IV)

Acrylonitrile adds smoothly also to 1-ethynylcyclopentanol and to 1-ethynyl-2-methylcyclohexanol with formation of the 2-cyanoethyl ethers (V) and (VI) in yields of greater than 90%:

(V)

(VI)

The results of the cyanoethylation of two stereoisomers of 4-ethynyl-1,2,5-trimethylpiperidinol (VII) show the effect of the spatial structure of a molecule on the addition of acrylonitrile. The low-melting isomer of (VII), m.p. 109-110°, reacting in dioxane solution at 30-40°, forms the 2-cyanoethyl ether (VIII) in 93% yield, about two-fifths of the original alcohol being recovered unchanged. Under the same conditions, the high-melting isomer of (VII), m.p. 176-177°, reacts with acrylonitrile only with great difficulty, and almost the whole of the alcohol is recovered unchanged. Thus, the hydroxyl group in the high-melting piperidinol (VII) is much more effectively screened, probably owing to its cis position with respect to the neighboring methyl group.

(VII)

(VIII)

Neither of the isomers of the piperidinol (VII) give any reaction with acrylonitrile in absence of catalyst (caustic potash) [2].

Cyanoethylation of the acetylenic glycol (IX), which is prepared by the condensation of acetylene with 5-hydroxy-2-pentanone, proceeds in two stages. The first acrylonitrile molecule reacts with the primary hydroxyl with formation of the monocyanoethyl ether (X), which then combines with a second acrylonitrile molecule with formation of the bis-2-cyanoethyl ether (XI):

(IX)

(X)

(XI)

The postulated position of the 2-cyanoethyl group in the monocyanoethyl ether (X) was confirmed by its nonreaction with naphthyl isocyanate, i.e. with respect to this reagent it behaves as a tertiary acetylenic alcohol. The glycol (IX), which has a free primary hydroxyl, readily reacts with naphthyl isocyanate.

EXPERIMENTAL

Reaction of Acrylonitrile with Ethynylmethylmethanol

Acrylonitrile (8.5 g, i.e. 0.16 mole) was added to a vigorously stirred mixture of 11.2 g (0.16 mole) of ethynylmethylmethanol (b.p. 102-107°) and 1.5 g of a 40% aqueous solution of potassium hydroxide, the rate of addition being adjusted so that the temperature of the mixture did not exceed 30°. When the addition was complete, the mixture was stirred at room temperature for four hours. It was then set aside overnight, and on the next day the alkali present was neutralized with dilute hydrochloric acid (1:1). The product was extracted with ether and the extract was dried with magnesium sulfate. Vacuum fractionation yielded 15.4 g of the 2-cyanoethyl ether of ethynylmethylmethanol (I; R = CH_3), b.p. 94-96° (16 mm); n_D^{20} 1.4351; d_4^{20} 0.9450; found MR 33.97; calculated MR 33.92.

Found %: N 10.65; 10.71

C_7H_9NO. Calculated %: N 11.38

The amount of the original alcohol recovered unchanged was 0.7 g.

The cyanoethylation of the other acetylenic alcohols was carried out in the same manner.

Reaction of Acrylonitrile with Ethylethynylmethanol

Reaction was between 50.5 g (0.6 mole) of ethylethynylmethanol (b.p. 123-124°) and 32 g (0.6 mole) of acrylonitrile in presence of 6 g of 40% aqueous caustic potash. The product was 73.5 g of the 2-cyanoethyl ether of ethylethynylmethanol (I; R = C_2H_5), b.p. 104-105° (15 mm); n_D^{20} 1.4393; d_4^{20} 0.9357; found MR 38.53; calculated MR 38.54.

Found %: N 9.83; 9.75

$C_8H_{11}NO$. Calculated %: N 10.22

The amount of the original alcohol recovered unchanged was 1.8 g.

Reaction of Acrylonitrile with Ethynylmethylpropylmethanol

Reaction was between 56 g (0.5 mole) of ethynylmethylpropylmethanol (2-propyl-3-butyn-2-ol) (b.p. 136-137°) and 26.5 g (0.5 mole) of acrylonitrile in presence of 6 g of 40% aqueous caustic potash. The product was 61.7 g of the 2-cyanoethyl ether of ethynylmethylpropylmethanol (II; R = n-C_3H_7), b.p. 112-114° (15 mm); n_D^{20} 1.4416; d_4^{20} 0.9163; found MR 47.61; calculated MR 47.78

Found %: N 8.39; 8.42

$C_{10}H_{15}NO$. Calculated %: N 8.48

The amount of the original alcohol recovered unchanged was 9.1 g.

Reaction of Acrylonitrile with Diethylethynylmethanol

Reaction was between 56 g (0.5 mole) of diethylethynylmethanol (b.p. 135-136°) and 26.5 g (0.5 mole) of acrylonitrile in presence of 6 g of 40% aqueous caustic potash. The product was 69.5 g of the 2-cyanoethyl ether of diethylethynylmethanol (III), b.p. 111-113° (15 mm); n_D^{20} 1.4438; d_4^{20} 0.9228; found MR 47.49; calculated MR 47.78.

Found %: N 8.62; 8.50
$C_{11}H_{15}NO$. Calculated %: N 8.48

The amount of the original alcohol recovered unchanged was 6.1 g.

Reaction of Acrylonitrile with Ethynyldiisopropylmethanol

Reaction was between 45 g (0.32 mole) of ethynyldiisopropylmethanol (b.p. 164-165°) and 20 g (0.38 mole) of acrylonitrile in presence of 5 g of 40% aqueous caustic potash. The usual treatment yielded 20.2 g of the 2-cyanoethyl ether of ethynyldiisopropylmethanol (IV), b.p. 126-128° (13 mm); n_D^{20} 1.4490; d_4^{20} 0.9260; found MR 55.90; calculated MR 57.10.

Found %: N 7.41; 7.54
$C_{13}H_{21}NO$. Calculated %: N 7.25

The amount of the original alcohol recovered unchanged was 30.1 g.

Reaction of Acrylonitrile with Ethynylhexylmethylmethanol

Reaction was between 45 g (0.32 mole) of ethynyl hexylmethylmethanol (1-ethynyl-1-methyl-1-heptanol) (b.p. 94-95°/19 mm) and 21.5 g (0.4 mole) of acrylonitrile in presence of 7 g of 40% aqueous caustic potash. The mixture was stirred for four hours at room temperature, and was then set aside for 48 hours. The product was 72.4 g of the 2-cyanoethyl ether of ethynylhexylmethylmethanol (II; R = n-C_6H_{13}), b.p. 115-116° (2.5 mm); n_D^{20} 1.4442; d_4^{20} 0.8997; found MR 61.42; calculated MR 61.63.

Found %: N 6.78; 6.83
$C_{15}H_{25}NO$. Calculated %: N 6.76

The amount of the original alcohol recovered unchanged was 7.8 g.

Reaction of Acrylonitrile with Ethynylmethyloctylmethanol

Reaction was between 55 g (0.3 mole) of ethynylmethyloctylmethanol (1-ethynyl-1-methyl-1-nonanol) (b.p. 138°/19 mm) and 16 g (0.3 mole) of acrylonitrile in presence of 6 g of 40% aqueous caustic potash. The product was 66.2 g of the 2-cyanoethyl ether of ethynylmethyloctylmethanol (II; R = n-C_8H_{17}), b.p. 148-150° (3.5 mm); n_D^{20} 1.4498; d_4^{20} 0.8693; found MR 70.99; calculated MR 70.87.

Found %: N 5.82; 5.92
$C_{17}H_{29}NO$. Calculated %: N 6.00

The amount of the original alcohol recovered unchanged was 3.5 g.

Reaction of Acrylonitrile with 1-Ethynylcyclopentanol

Reaction was between 22 g (0.2 mole) of 1-ethynylcyclopentanol (b.p. 155-156°) and 11 g (0.2 mole) of acrylonitrile in presence of 3 g of 40% aqueous caustic potash. The product was 30.5 g of the 2-cyanoethyl ether of 1-ethynylcyclopentanol (V), b.p. 125-127° (14 mm); n_D^{20} 1.4684; d_4^{20} 0.9936; found MR 45.63; calculated MR 45.58.

Found %: C 73.10; 73.28; H 7.83; 7.83
$C_{10}H_{13}NO$. Calculated %: C 73.62; H 7.97

The amount of the original alcohol recovered unchanged was 1.5 g.

Reaction of Acrylonitrile with 1-Ethynyl-2-methylcyclohexanol

Reaction was between 49 g (0.355 mole) of 1-ethynyl-2-methylcyclohexanol (b.p. 57-58°/3 mm) and 21.2 g

(0.4 mole) of acrylonitrile in presence of 7 g of 40% aqueous caustic potash. The mixture was stirred for seven hours at room temperature and then set aside for 48 hours. The product was 56.6 g of the 2-cyanoethyl ether of 1-ethynyl-2-methylcyclohexanol (VI), b.p. 135-136° (10 mm); n_D^{15} 1.4710; d_4^{20} 0.9783; found MR 61.69; calculated MR 61.84.

Found %: N 7.79; 7.88
$C_{12}H_{17}NO$. Calculated %: N 7.89

The amount of the original alcohol recovered unchanged was 6.8 g.

Reaction of Acrylonitrile with 4-Ethynyl-1,2,5-trimethylpiperidinol

a) A mixture of 51 g (0.3 mole) of the low-melting isomer of 4-ethynyl-1,2,5-trimethylpiperidinol (VII) (m.p. 109-110°), 20 g (0.38 mole) of acrylonitrile, 6 g of 40% aqueous caustic potash, and 25 ml of dioxane was stirred at 30-40° for four hours and at room temperature for six hours; it was then set aside overnight. The product was 35.3 g of the 2-cyanotheyl ether of 4-ethynyl-1,2,5-trimethylpiperidinol (VIII), b.p. 135-137° (3 mm); n_D^{15} 1.4817; d_4^{15} 0.9943; found MR 63.04; calculated MR 63.37.

Found %: N 13.35; 13.29
$C_{13}H_{18}N_2O$. Calculated %: N 12.72

The amount of the original piperidinol recovered unchanged was 22.4 g.

b) A mixture of 17 g (0.1 mole) of the high-melting isomer of 4-ethynyl-1,2,5-trimethylpiperidinol (VII) (m.p. 176-177°), 8 g (0.15 mole) of acrylonitrile, 2 g of 40% aqueous caustic potash, and 50 ml of dioxane was stirred at 40-45° for eight hours and then set aside overnight. The product, amounting to 3.7 g, boiled at 110-130° (13 mm). The amount of the original piperidinol recovered unchanged was 13.8 g.

Reaction of Acrylonitrile with 4-Ethynyl-1,4-pentanediol

a) Reaction was between 10 g (0.08 mole) of the acetylenic glycol (IX) (b.p. 105-106°/2.5 mm) and 4.1 g (0.08 mole) of acrylonitrile in presence of 1.5 g of 40% aqueous caustic potash. The main product was 9.4 g of the 2-cyanoethyl ether (X), b.p. 148-150° (3 mm); n_D^{15} 1.4608; d_4^{20} 1.0231.

Found %: C 66.27; 66.09; H 7.99; 8.11
$C_{11}H_{15}NO_3$. Calculated %: C 66.30; H 8.28

The reaction also gave 3.2 g of the bis-2-cyanoethyl ether of 4-ethynyl-1,4-pentanediol (XI), b.p. 190-192° (3 mm); n_D^{15} 1.4801; d_4^{20} 1.0276.

Found %: N 12.22; 12.19
$C_{15}H_{18}N_2O_2$. Calculated %: N 11.96

b) Reaction was between 7.5 g (0.06 mole) of the acetylenic glycol (IX) and 6.4 g (0.12 mole) of acrylonitrile in presence of 2.5 g of 40% aqueous caustic potash. The main product was 7.4 g of the bis-2-cyanoethyl ether of 4-ethynyl-1,4-pentanediol (XI), b.p. 182-185° (3.5 mm). The reaction gave also 4.5 g of the 2-cyanoethyl ether (X), b.p. 153-156° (3.5 mm).

Reaction of Acrylonitrile with the 2-Cyanoethyl Ether (X)

Reaction was between 9 g (0.05 mole) of the 2-cyanoethyl ether (X) and 4.2 g (0.08 mole) of acrylonitrile in presence of 1.5 g of 40% aqueous caustic potash. The product was 6.9 g of the bis-2-cyanoethyl ether of 4-ethynyl-1,4-pentanediol (XI), b.p. 190-195° (3 mm), and 3.4 g of the original 2-cyanoethyl ether (X) was recovered unchanged.

SUMMARY

1. Some secondary and tertiary acetylenic alcohols were cyanoethylated in presence of caustic potash, and the corresponding 2-cyanoethyl ethers were obtained in good yield. In the case of ethynyldiisopropylmethanol the greater part of the original alcohol was recovered unchanged.

2. Of the two isomers of 4-ethynyl-1,2,5-trimethylpiperidinol (VII), only the low-melting isomer reacts with acrylonitrile and gives the corresponding 2-cyanoethyl ether (VIII). The high-melting isomer of this piper-

idinol does not react with acrylonitrile under the usual conditions.

3. The acetylenic glycol (IX) reacts with acrylonitrile with formation of mono- and bis-2-cyanoethyl ethers, and the first acrylonitrile molecule reacts at the primary hydroxyl group.

EFFECT OF ENOLIZATION ON THE ABILITY OF β-DICARBONYL COMPOUNDS TO UNDERGO MICHAEL AND C-ALKYLATION REACTIONS

I.N. Nazarov, S.I. Zavylov, and M.S. Burmistrova

In a series of previous investigations [1-4] we have studied the condensation of dihydroresorcinol derivatives with various α,β-unsaturated carbonyl compounds, and on the basis of these reactions we have developed methods for the preparation of some bicyclic ketones that are of interest as intermediate products in the synthesis of polycyclic compounds related to steroids. The present communication presents new data on the alkylation and Michael condensation of cyclic β-diketones, and an examination is made of the dependence of the course of these reactions on the extent of enolization of the carbonyl compounds.

The dual reactivity of β-diketones in nucleophilic substitution reactions is greatly dependent on the structures of the reactants and the character of the solvent (medium); it is governed by very complex laws. We have now found, for example, that bromomethyl 1-hydroxycyclohexyl ketone (II) reacts when heated with the potassium derivative of 2-methyldihydroresorcinol (2-methyl-1,3-cyclohexanedione) in methanol solution with formation of the corresponding enol ether (III) in 40% yield, whereas 2-bromoacetophenone (IV), a substance of similar structure, reacts under these conditions with formation of the C-derivative (V) in 44% yield. When shaken in the cold with 2% hydrochloric acid, the enol ether (III) is hydrolyzed quantitatively into the original 2-methyldihydroresorcinol, whereas the triketone (V) is not affected under these conditions. When heated with 5% caustic potash solution, the triketone (V) undergoes hydrolytic scission with formation of the diketo acid (VI), which then recyclizes into the corresponding derivative of 2-cyclopenten-1-one (VII):

The low rate of the C-alkylation of dihydroresorcinol derivatives and their characteristic tendency to form enol ethers are evidently to be explained by the high degree of enolization of these β-diketones, a fact that is clearly manifest when a comparative study is made of the alkylation of 3-methyltetronic acid (XI), dihydroresorcinol, dimedone (5,5-dimethyl-1,3-cyclohexanedione) [5], 2-methyl-1,3-indandione (VIII), and ketones of the cyclohexane series [5]. The sodium salt of 3-methyltetronic acid (XI) is completely enolized in aqueous solution [6], but is not methylated to an appreciable extent when boiled with methyl iodide in methanol for three hours. On the other hand, the only slightly enolized 2-methyl-1,3-indandione reacts smoothly under the same conditions with formation of 2,2-dimethyl-1,3-indandione (IX), the structure of which is confirmed by its hydrolytic scission to the known o-isobutyrylbenzoic acid (X) [7]. Unlike dihydroresorcinol, which is com-

pletely enolized in aqueous solution [5], 2-methyl-1,3-indandione readily gives the C-methyl derivative (IX) even in a less polar solvent (dioxane).

(VIII) (IX) (X) (XI, XII)

(XI) R = CH_3, (XII) R = C_2H_5

Derivatives of the feebly enolized cyclohexanone can be C-alkylated much more readily than dihydroresorcinol derivatives [9,10]. For example, when the potassium derivative of 2-methyl-3-oxocyclohexanecarbonitrile (XIII) is treated with allyl bromide in tert-butyl alcohol, rapid formation occurs of 2-allyl-2-methyl-3-oxocyclohexanecarbonitrile (XIV), the structure of which was proved by its conversion into the formyl derivative (XV) by the action of formic ester and sodium:

(XIII) (XIV) (XV)

The inhibiting effect of enolization on the C-alkylation of cyclic β-diketones can be seen from Table 1.

In order to study the effect of enolization on the ability of keto-enols to undergo Michael condensation, we investigated the cyanoethylation of the 3-alkyltetronic acids (XI) and (XII), 2-methyl-1,3-indandione, ethyl 2-oxocyclopentanecarboxylate, and ethyl 2-oxocyclohexanecarboxylate. As shown previously [1-4], heat must be applied in order to effect the reaction of 3-alkyltetronic acids, dihydroresorcinol, and dimedone with acrylonitrile in aqueous dioxane in presence of caustic soda. In contrast to these β-diketones, the only slightly enolized 2-methyl-1,3-indandione reacts fairly readily with acrylonitrile, even at 20°, and forms the 2-cyanoethyl derivative (XVI) in 55% yield.

(XVI) (XVII) (XVIII)

In aqueous solutions of dioxane in presence of one-sixth of an equivalent of caustic soda the feebly enolized ethyl 2-oxocyclopentanecarboxylate reacts vigorously with acrylonitrile at room temperature (with evolution of heat), and after only 30 minutes a 75% yield of the 2-cyanoethyl derivative (XVII) is obtained. Under the same conditions, the more strongly enolized ethyl 2-oxocyclohexanecarboxylate gives a yield of only 33% of the 2-cyanoethyl derivative (XVIII).

The deactivating effect of enolization on the cyanoethylation of carbonyl compounds under comparable conditions can be seen clearly from an examination of Tables 2 and 3.

EXPERIMENTAL

Reaction of the Potassium Derivative of 2-Methyldihydroresorcinol with Bromomethyl 1-Hydroxycyclohexyl Ketone

A solution of the potassium derivative of 2-methyldihydroresorcinol was prepared from 0.8 g of potassium

TABLE 1

Methylation of β-Dicarbonyl Compounds (Action of Methyl Iodide on the Sodium Derivatives)

Formula of compound	Amount of enol in H_2O (%)	Solvent	Reaction temperature (°C)	Duration of reaction (hours)	Yield (%)
	0.2 [11]	Aqueous alcohol	20	2-3	75 [12]
	1.0 [11]	Methanol Dioxane	At boil 100	2 ½	67 70
	100 [3]	Methanol Dioxane Aqueous alcohol	At boil 100 20	3 ½ 3	40 [1] 0 0
	100 [6]	Methanol	At boil	3	0

TABLE 2

Cyanoethylation of β-Dicarbonyl Compounds in tert-Butyl Alcohol Solution in presence of Triton B

Formula of compound	Amount of enol in H_2O (%)	Reaction temperature (°C)	Duration of reaction (hours)	Yield [a] (%)
$CH_2(COOC_2H_5)_2$	Traces [8, 13]	30	2	83 [14]
$CH_3COCH_2COOC_2H_5$	0.5 [11]	30-40	1	50 [15]

and 2 g of 2-methyldihydroresorcinol (I) (m.p. 209-210°) in 15 ml of methanol, and 3 g of bromomethyl 1-hydroxycyclohexyl ketone (II) b.p. 103-105° (0.5 mm), n_D^{25} 1.5170 [16] was added. The mixture was refluxed for three hours. Methanol was distilled off under reduced pressure, and the residue was treated with 10 ml of water and 10 ml of ether. The precipitated crystals were filtered off and washed with ether. The product was 1.7 g (40%) of the enol ether (III), m.p. 135-136° (from aqueous methanol).

Found %: C 67.55; 67.48; H 8.19; 8.02

$C_{18}H_{22}O_4$. Calculated %: C 67.1; H 8.3

When the enol ether (III) was shaken in the cold with 2% hydrochloric acid, the original 2-methyldihydroresorcinol was formed in almost quantitative yield.

Reaction of the Potassium Derivative of 2-Methyldihydroresorcinol with 2-Bromoacetophenone

A solution of the potassium derivative of 2-methyldihydroresorcinol was prepared from 1 g of potassium and 3.2 g of 2-methyldihydroresorcinol in 25 ml of methanol, and 4.8 g of 2-bromoacetophenone was added.

[a] The yields refer to the bis-2-cyanoethyl derivatives.

TABLE 3

Cyanoethylation of ß-Dicarbonyl Compounds in Aqueous Dioxane Solution in Presence of One-Sixth of an Equivalent of Sodium Hydroxide

Formula of compound	Amount of enol in H_2O (%)	Reaction temperature (°C)	Duration of reaction (hours)	Yield (%)
	0.2 [11]	20-30	1/2	75

	100 [8]	20	5	0

•The yields refer to bis-2-cyanoethyl derivatives.

••The reaction was carried out in presence of one equivalent of sodium hydroxide.

The mixture was refluxed for three hours. When cool, the solution was filtered and evaporated to dryness under reduced pressure. The residue was treated in the cold with sodium carbonate solution, heated for 10-15 minutes at 60-70° with methanol acidified with a few drops of concentrated hydrochloric acid (to remove traces of the enol ether), and washed with water. The product was 2.2 g (44%) of the triketone (V), m.p. 125-128° (from methanol).

	Found %:	C 73.70; 73.84; H 6.73; 6.59
$C_{23}H_{22}O_3$.	Calculated %:	C 73.75; H 6.6

Hydrolytic Scission of the Triketone (V)

A mixture of 2 g of the above-described triketone (V), 1 g of caustic potash, and 20 ml of water was

heated at 60-70° until the crystals had dissolved completely. Acidification of the cooled solution with concentrated hydrochloric acid gave a precipitate of 1.6 g (80%) of the keto acid (VII), m.p. 94-95° (from water).

Found %: C 73.73; 73.82; H 6.42; 6.66
$C_{12}H_{12}O_3$. Calculated %: C 73.7; H 6.6
Titration equivalent found: 243.6; 250
$C_{12}H_{12}O_3$. Titration equivalent calculated: 244

The 2,4-dinitrophenylhydrazone melted at 131-132° (from methanol).

Found %: N 14.57; 14.90
$C_{21}H_{20}O_7N_4$. Calculated %: N 13.20

Methylation of 2-Methyl-1,3-indandione

1. A solution of the sodium derivative of 2-methyl-1,3-indandione was prepared from 0.12 g of sodium and 0.8 g of 2-methyl-1,3-indandione (VIII) (m.p. 84-85°) in 3 ml of methanol, and 1.5 g of methyl iodide was added. The mixture was refluxed for two hours, and was then cooled and treated with a solution of 2 g of sodium carbonate. Extraction with chloroform and removal of solvent gave a residue which crystallized completely, the product being 0.8 g (87%) of 2,2-dimethyl-1,3-indandione (IX), m.p. 106-107° (from aqueous methanol). The literature gives m.p. 107-108° [17].

2. A mixture of 0.2 g of finely ground sodamide, 0.8 g of 2-methyl-1,3-indandione, and 10 ml of dioxane was stirred at 60-70° for 10 minutes and then, after the addition of 1.5 g of methyl iodide, heated for a further 20 minutes at 100°. The solution was cooled and evaporated to dryness under reduced pressure; the residue was treated with 10 ml of saturated sodium carbonate solution. The product was 0.65 g (72%) of 2,2-dimethyl-1,3-indandione (IX), m.p. 106-107° (from aqueous methanol).

When dihydroresorcinol was treated under similar conditions, practically no C-methylation occurred.

Hydrolytic Scission of 2,2-Dimethyl-1,3-indandione

A mixture of 0.6 g of 2,2-dimethyl-1,3-indandione, 0.6 g of caustic potash, and 10 ml of water was stirred at 50-60° until solution was complete (about 20 minutes). Acidification of the cooled solution with concentrated hydrochloric acid gave a precipitate of 0.6 g (86%) of o-isobutyrylbenzoic acid (X), m.p. 120-121° (from water). The literature [7] gives m.p. 120-121°.

Reaction of Allyl Bromide with the Potassium Derivative of 2-Methyl-3-oxocyclohexanecarbonitrile

A solution of potassium tert-butoxide was prepared from 0.7 g of potassium and 30 ml of tert-butyl alcohol, and 2.5 g of 2-methyl-3-oxocyclohexanecarbonitrile (XIII) (m.p. 57-58°) [18] was added. The mixture was stirred while 3 g of allyl bromide was added in portions. After a few minutes a copious precipitate of potassium bromide formed. After standing for two hours at room temperature, the solution was evaporated to dryness under reduced pressure and the residue was treated with 10 ml of water and extracted with ether. The product was 1.7 g (51%) of 2-allyl-2-methyl-3-oxocyclohexanecarbonitrile (XIV), b.p. 103-107° (2 mm); n_D^{20} 1.4850.

Found %: C 74.67; 74.52; H 8.62; 8.77; N 7.68; 7.87
$C_{11}H_{15}ON$. Calculated %: C 74.6; H 8.5; N 7.9

The semicarbazone melted at 175-176° (from aqueous methanol).

Found %: N 23.67; 23.79
$C_{12}H_{18}ON_4$. Calculated %: N 23.9

Formylation of 2-Allyl-2-methyl-3-oxocyclohexanecarbonitrile

Ethyl formate (4 g) and the above-described 2-allyl-2-methyl-3-oxocyclohexanecarbonitrile (XIV) (4.6 g) were added to 1 g of granulated sodium in 50 ml of ether. The mixture was stirred for one hour and then set aside for 12 hours at room temperature. The precipitated sodium derivative was then filtered off, washed with ether, and treated with ice and dilute (1:1) hydrochloric acid. The oil that separated was extracted with ether and vacuum-distilled. The product was 2.4 g (46%) of 2-allyl-4-formyl-2-methyl-3-oxocyclohexanecarbonitrile (XV), b.p. 123-126° (1 mm); n_D^{20} 1.5160.

	Found %:	C 70.50; 70.53;	H 7.33; 7.19;	N 6.55; 6.70
$C_{12}H_{13}O_3N$.	Calculated %:	C 70.3;	H 7.3;	N 6.8

The substance gives a dark coloration with ferric chloride, and it dissolves in cold dilute alkali.

Cyanoethylation of 2-Methyl-1,3-indandione

Acrylonitrile (4 g) was added to a solution of the sodium derivative of 2-methyl-1,3-indandione prepared from 0.08 g of caustic soda, 1.6 g of 2-methyl-1,3-indandione (VIII), and 12 ml of aqueous dioxane (1:3). The mixture was set aside at 20° for five hours and then acidified to congo red with dilute (1:1) hydrochloric acid. It was then treated with a solution of sodium carbonate, and the product was extracted with ether. When the solvent was removed, the residue crystallized completely. The product was 1.2 g (55%) of 2-methyl-1,3-dioxo-2--indanpropionitrile (XVI), m.p. 84-85° (from aqueous methanol).

	Found %:	C 72.95; 73.03;	H 5.20; 5.33;	N 6.85; 6.91
$C_{13}H_{11}O_2N$.	Calculated %:	C 73.2;	H 5.1;	N 6.6

When treated under similar conditions, dihydroresorcinol, dimedone, 2-methyldihydroresorcinol, and the 3--alkyltetronic acids (XI) and (XII) do not undergo cyanoethylation.

Cyanoethylation of Ethyl 2-Oxocyclopentanecarboxylate

To a stirred solution of 0.28 g of caustic soda in 10 ml of water, 6.4 g of ethyl 2-oxocyclopentanecarboxylate (b.p. 103-105°/15 mm; n_D^{20} 1.4505 [19]) and a solution of 4 g of acrylonitrile in 34 ml of dioxane were added in quick succession. The temperature of the solution rose slowly to 20-30°. After 30 minutes the reaction mixture was cooled with ice, acidified with dilute (1:1) hydrochloric acid to congo red, and extracted with chloroform. After removal of solvent, the residue was vacuum-fractionated. The product was 6.4 g (75%) of 1--(ethoxycarbonyl)-2-oxocyclopentanepropionitrile (XVII), b.p. 176-178° (8 mm); n_D^{20} 1.4644.

	Found %:	C 62.78; 62.95;	H 7.01; 7.11;	N 6.85; 6.93
$C_{11}H_{15}O_3N$.	Calculated %:	C 63.1;	H 7.2;	N 6.7

The semicarbazone melted at 147-148° (from aqueous methanol).

	Found %:	N 20.72; 20.85
$C_{12}H_{18}O_3N_4$.	Calculated %:	N 21.1

Cyanoethylation of Ethyl 2-Oxocyclohexanecarboxylate

When ethyl 2-oxocyclohexanecarboxylate (b.p. 103-107°/11 mm; n_D^{20} 1.4750 [19]) was cyanoethylated under the above-described conditions, no evolution of heat was observed. Treatment of 6.8 g of the 2-oxocyclohexanecarboxylic ester gave 3 g (33%) of 1-(ethoxycarbonyl)-2-oxocyclohexanepropionitrile (XVIII), b.p. 167-169° (7 mm); n_D^{20} 1.4715 [20]. In addition 2.4 g of the 2-oxocyclohexanecarboxylic ester was recovered unchanged. The semicarbazone of (XVIII) melted at 168-169° (from aqueous methanol).

	Found %:	N 19.69; 19.83
$C_{13}H_{20}O_3N_4$.	Calculated %:	N 20.0

SUMMARY

1. When the potassium derivative of 2-methyldihydroresorcinol was treated with bromomethyl 1-hydroxycyclohexyl ketone (II) in methanol solution, the corresponding enol ether (III) was formed in 40% yield. Under the same conditions, reaction between the potassium derivative of 2-methyldihydroresorcinol and 2-bromoacetophenone gave the C-derivative (V) in 44% yield.

2. When boiled for three hours with methyl iodide in a methanol medium, 3-methyltetronic acid (XI) was not methylated, whereas 2-methyl-1,3-indandione gave the C-methyl derivative (IX) in 70% yield.

3. Unlike dihydroresorcinol, 2-methyl-1,3-indandione readily undergoes C-methylation in dry dioxane.

4. In condensations with acrylonitrile, 2-methyl-1,3-indandione reacts more readily than dihydroresorcinol derivatives and 3-alkyltetronic acids.

5. In aqueous dioxane in presence of caustic alkali, the cyanoethylation of ethyl 2-oxocyclohexanecarboxylate is more difficult than that of ethyl 2-oxocyclopentanecarboxylate.

6. These examples of low nucleophilic reactivity in keto-enol compounds is to be explained by the deactivating effect of enolization.

POSSIBILITY OF FORMING CYCLOPENTADIENE FROM HETEROCYCLIC COMPOUNDS CONTAINING FIVE CARBON ATOMS

N.I. Shuikin and V.A. Tulupov

Cyclopentadiene was synthesized by Zelinsky and Levina [1] in accordance with the scheme:

As is well known, cyclopentadiene is formed in the high-temperature treatment of coal, petroleum, hydrocarbon gases, and other organic substances. For example, it has been isolated from the products obtained in the coking of coal [2] and in the cracking of gas oil [3, 4]. Volzhinsky and Shcheglova [5] found that a fraction of boiling range 28-50° obtained in the cracking of kerosene at low pressure contained about 35% of dienes, mainly cyclopentadiene. There are references to the presence of cyclopentadiene in pyrolysis products from natural gas [6], and also in illuminating gas and water gas [7]. Kazansky and Plate [8] detected cyclopentadiene in pyrolysis products from cyclopentane. In addition to the latter, cyclopentadiene is formed also as the result of a disproportionation reaction between hydrogen and cyclopentene, which occurs at 450° and 500° on an alumina-chromia catalyst and at 180-200° on palladium black [9]. Cyclopentadiene is formed also in the pyrolysis of the lower-paraffins [10], in the pyrolysis of olefins [11], and even in the cracking of phenol and alkylbenzenes [12].

Fig. 1. Fractionation curve for the transformation products of piperidine

Fig. 2. Dependence of the yields of cyclopentadiene (Curve 1) and piperylene (Curve 2) on the reciprocal of the space velocity for the passage of tetrahydro-2-methylfuran over $TiO_2 + Al_2O_3$ (5 mole-%)

The problem of the direct preparation of cyclopentadiene by the catalytic cyclization of piperylene was first tackled by Kennedy and Hetzel [13], who showed that a condensate containing up to 9% of cyclopentadiene is obtained from piperylene at 600-620° under low pressure. On the other hand, various investigations [14-17] have shown that certain heterocyclic compounds may be converted into piperylene. It was considered to be of interest, therefore, to determine whether it is possible in principle to prepare cyclopentadiene directly from simple heterocyclic compounds under the conditions required for the cyclization of piperylene. With this object

we investigated the contact-catalysis reactions of tetrahydro-2-methylfuran, tetrahydro-2 methylthiophene, 2--methylpyrrolidine, and piperidine.

The most accessible of these compounds is tetrahydro-2-methylfuran, and most of the experiments designed to determine the optimum conditions for reaction, to elucidate various matters relating to the mechanism of the formation of cyclopentadiene, and to select the most active catalyst were therefore carried out with this substance. It was shown that the optimum conditions of temperature and pressure are 600° and 30-35 mm. Of the catalysts investigated - Al_2O_3, Al_2O_3 + MnO (1:2), $ZrSiO_4$, TiO_2 + Al_2O_3 (5, 10, and 25 mole-% of Al_2O_3), and TiO_2 + ThO_2 (3:1) - the mixed catalyst TiO_2 + Al_2O_3 (5 or 10% Al_2O_3) was found to be the most active. Hence, in giving the results of our investigation into the reactions of the above-mentioned heterocycles, we shall confine ourselves to the work with titania-alumina catalysts.

We found that, over the catalyst TiO_2 + Al_2O_3 (5 mole-% Al_2O_3) at 600° and 30-35 mm pressure, tetrahydro-2-methylfuran and tetrahydro-2-methylthiophene, passed at a space velocity of 1 $hour^{-1}$, are converted into cyclopentadiene at a yield of about 20%. When passed over TiO_2 + Al_2O_3 (10 mole-%) at a space velocity of 0.2 $hour^{-1}$, they give a yield of only about 5% of cyclopentadiene. In both cases an appreciable amount of piperylene is also formed (see below). As regards 2-methylpyrrolidine and piperidine, in contact with TiO_2 + Al_2O_3 (5 mole-% Al_2O_3) only the latter gives traces of cyclopentadiene, the bulk of the catalyzate being pyridine, as can be seen from the fractionation curve of one sample (Fig. 1). In addition to pyridine, pyrrole is obtained in this reaction in yields of up to 5.4%.

Under the given conditions, 2-methylpyrrolidine is converted mainly into 2-methylpyrrole.

In order to elucidate certain matters relating to the mechanism of the formation of cyclopentadiene, we investigated the dependence of the yields of cyclopentadiene and piperylene on the time of contact of tetrahydro-2-methylfuran with the catalyst. In addition, a comparison was made of the degrees of conversion of piperylene and of tetrahydro-2-methylfuran into cyclopentadiene for identical times of contact. It was found that for a given catalyst tetrahydro-2-methylfuran gave a higher yield of cyclopentadiene than piperylene did, although the reverse would have been expected if the formation of cyclopentadiene proceeds through the intermediate stage of piperylene. It was shown also that, in the transformation of tetrahydro-2-methylfuran, the formation of cyclopentadiene and the formation of piperylene (Fig. 2) proceed both as parallel and as successive reactions, the yield maxima being displaced with respect to each other. For a certain time of contact (Fig. 2) the two reactions appear to be independent, but after a sufficiently long period of contact cyclopentadiene is formed not only directly from tetrahydro-2-methylfuran, but also indirectly via piperylene.

With the same object, we investigated the effect of the presence of bases in the original tetrahydro-2-methylfuran on the yield of cyclopentadiene. Tetrahydro-2-methylfuran containing 5% by weight of piperidine was treated under the conditions indicated above over TiO_2 + Al_2O_3 (5 mole-%). The yield of cyclopentadiene then fell from 8.2% to 0.7%. It was thus shown that one of the factors governing catalytic action was the "acidity" of the catalyst.

EXPERIMENTAL

Synthesis of the Starting Substances and Preparation of the Catalysts

Tetrahydro-2-methylfuran and piperidine were prepared from 2-methylfuran and pyridine respectively by hydrogenation (at 125° and 150° respectively) by the flow method in presence of nickel deposited on a nickel-aluminum alloy (27% Ni) prepared by a method previously described by one of us [18]. The hydrogenation products were fractionated over sodium through a 30-plate column. The properties of the products were: tetrahydro-2-methylfuran - b.p. 79-79.2° (745 mm); d_4^{20} 0.8582; n_D^{20} 1.4087; piperidine - b.p. 105.5° (760); d_4^{20} 0.8640; n_D^{20} 1.4592. According to the literature, tetrahydro-2-methylfuran [19] has b.p. 78.5-80° (746); d_4^{20} 0.8582; n_D^{20} 1.4072; and piperidine [20] has b.p. 106°; d_4^{20} 0.8612; and n_D^{20} 1.4523.

Tetrahydro-2-methylthiophene and 2-methylpyrrolidine were prepared by reaction of tetrahydro-2-methylfuran with hydrogen sulfide and ammonia respectively in presence of catalysts [20]. Each catalyzate was fractionated twice from a Favorsky flask, and tetrahydro-2-methylthiophene and 2-methylpyrrolidine were prepared in yields of 36% and 20% respectively. The constants of the products were: tetrahydro-2-methylthiophene - b.p. 131-132° (757 mm); d_4^{20} 0.9533; n_D^{20} 1.4907; and 2-methylpyrrolidine - b.p. 104-105° (750 mm); d_4^{20} 0.8312; n_D^{20} 1.4380. Yuryev gives the following constants [20]: tetrahydro-2-methylthiophene - b.p. 131.2-131.5°; d_4^{20}

0.9541; n_D^{20} 1.4922; 2-methylpyrrolidine - b.p. 104-104.5° (755 mm); d_4^{20} 0.8307; n_D^{20} 1.4372.

Piperylene was obtained by fractionation of the commercial product through a 70-plate column. A narrow fraction was collected; boiling range 41.7-43.8° (757 mm); d_4^{20} 0.6834; n_D^{20} 1.4317; it was a mixture of cis- and trans-piperylenes. For a mixture of cis- and trans-piperylenes, the literature [21] gives b.p. 43°; d_4^{20} 0.685; n_D^{20} 1.4309.

Samples of titania-alumina catalyst having alumina contents of 5 and 10 mole-% were prepared by carefully grinding a mixture of pure titania and freshly precipitated aluminum hydroxide in a mortar. The mixture was formed into the form of small balls, and these were given a preliminary drying at 150°.

Catalytic Transformations of Tetrahydro-2-methylfuran, Tetrahydro-2-methylthiophene, 2-Methylpyrrolidine, and Piperidine

The experiments were carried out at 600° and 30-40 mm pressure in a silica tube of internal diameter 16 mm. The substances were passed to the catalysis tube from an automatic buret. In the experiments on tetrahydro-2-methylfuran, piperylene, and piperidine, we took 50 g of each substance, and in those on tetrahydro-2-methylthiophene and 2-methylpyrrolidine we took 25 g and 20 g respectively. In the kinetic experiments 15 g of tetrahydro-2-methylfuran was taken. The catalysis products were collected in a water-cooled receiver and in three successive traps, of which two were immersed in a mixture of dry ice and methanol, and the third was immersed in liquid nitrogen. The extent of cracking was determined by the weight of liquid catalyzate. Analysis for the cyclopentadiene content of the catalyzate was carried out by the method propored by Afanasyev [22]. The total diene content was determined by reaction with maleic anhydride in accordance with Krauze, Kogan, and Polievktova's method [23], the piperylene content being found by difference. The catalyzates obtained in experiments with tetrahydro-2-methylfuran and piperidine were fractionated through a column, but the tetrahydro-2-methylthiophene and 2-methylpyrrolidine catalyzates were fractionated from a Favorsky flask. The results obtained in experiments on tetrahydro-2-methylfuran and tetrahydro-2-methylthiophene are given in Table 1.

TABLE 1

Transformations of Tetrahydro-2-methylfuran and Tetrahydro-2-methylthiophene in presence of $TiO_2 + Al_2O_3$ at 600°

Expt. No.	Starting substance	Content in catalyzate (mole-%)	Experimental conditions: Pressure (mm)	Experimental conditions: Space velocity ($hour^{-1}$)	Yield of catalyzate (% by wt.)	Yield of dienes (%): Cyclopentadiene	Yield of dienes (%): Piperylene
1	Tetrahydro-2-methylfuran	5	30-35	1	95.0	18.7	40.0
2	Tetrahydro-2-methylfuran	5	30-35	0.5	93.7	6.2	48.3
3	Tetrahydro-2-methylfuran	10	30-40	0.2	70.0	4.6	28.5
4	Tetrahydro-2-methylfuran + 5% piperidine	5	30-40	0.5	89.2	0.7	33.4
6	Tetrahydro-2-methylthiophene	5	30-35	1	95.4	20.3	42.1
7	Tetrahydro-2-methylthiophene	10	30-35	0.2	68.7	5.0	27.9

The catalyzates of Experiments 1, 2, and 3 were combined and fractionated through a 30-plate column. The following fractions were collected at 751 mm: Fraction I, b.p. 24-41° (5.7 g); d_4^{20} 0.6375; n_D^{20} 1.3824; bromine value 203.1; content of unsaturateds 89.9% calculated as C_5; Fraction II, b.p. 41-44° (83.7 g); d_4^{20} 0.6824; n_D^{20} 1.4329; Residue (12.3 g), which was not investigated. The catalyzates of Experiments 6 and 7 were distilled at 757 mm from a Favorsky flask. Two fractions were collected: Fraction of b.p. 25-41° (1.7 g); n_D^{20} 1.3850 and Fraction of b.p. 41-44° (23.4 g); n_D^{20} 1.4330; they were not investigated further. The results of the kinetic measurements on tetrahydro-2-methylfuran are given in Tables 2 and 3.

TABLE 2

Yield of Cyclopentadiene in the Transformations of Tetrahydro-2-methylfuran and Piperylene over $TiO_2 + Al_2O_3$

Expt. No.	Content of Al_2O_3 in catalyzate (mole-%)	Experimental conditions: Pressure (mm)	Temperature (°C)	Space velocity ($hour^{-1}$)	Starting substance	Yield of cyclopentadiene (% of theory)
1	5	30-35	600	0.5	Tetrahydro-2-methylfuran	6.2
2	5	30-35	600	0.5	Piperylene	2.0
3	10	30-40	600	0.2	Tetrahydro-2-methyl furan	4.6
4	10	30-40	600	0.2	Piperylene	2.9

TABLE 3

Dependence of the Yields of Cyclopentadiene and Piperylene on the Space Velocity of the Passage of Tetrahydro-2-methylfuran over $TiO_2 + Al_2O_3$ (5 mole-%) at 600° and 25-30 mm

Expt. No.	Space velocity ($hour^{-1}$)	Yield of dienes (%): Cyclopentadiene	Piperylene	Expt. No.	Space velocity ($hour^{-1}$)	Yield of dienes (%): Cyclopentadiene	Piperylene
1	5	5.1	Not investigated	4	0.3	4.6	52.3
2	1	20.0	39.7	5	0.2	3.6	59.3
3	0.7	9.4	36.3	6	0.1	6.5	25.1

The transformations of pipendine (50 g) were investigated in presence of $TiO_2 + Al_2O_3$ (5 mole-% Al_2O_3). In the catalyzate, which amounted to 33.5 g, only traces of cyclopentadiene could be detected. The catalyzate was fractionated through a 30-plate column (see Fig. 1), and the following fractions were collected:

	B.p. (°C)	Amount (g)	Yield (% of catalyzate)	d_4^{20}	n_D^{20}
Fraction I	82-116	0.8	2.3	—	1.4420
Fraction II	116	23.0	68.7	0.9779	1.5073
Fraction III	116-130	1.7	5.1	0.9738	1.5062
Fraction IV	130-132	1.8	5.4	0.9697	1.5044
	Residue	5.2	15.5	—	—

The individual compounds obtained were pyridine (Fraction II) and pyrrole (Fraction IV). For pyrrole the literature [24] gives b.p. 130-131°; d_4^{20} 0.9891; and n_D^{20} 1.5035.

The transformations of 2-methylpyrrolidine were also carried out in presence of $TiO_2 + Al_2O_3$ (5 mole-% Al_2O_3), the temperature being 600° and the space velocity 0.5 $hour^{-1}$. From 20 g of 2-methylpyrrolidine 19.0 g of catalyzate was obtained, and this was fractionated from a flask fitted with a column. A very small amount (0.5 g) came over in the range 79-143° (741 mm), and the bulk (14.7 g) came over at 148-151°. This substance gave a reaction for pyrrole and had d_4^{20} 0.9289 and n_D^{20} 1.5003. For 2-methylpyrrole Yuryev gives the following constants [20]: b.p. 148.5-150°; d_4^{20} 0.9295 and n_D^{20} 1.5012. The small residue was not investigated. In the course of the transformations of the nitrogen-containing heterocycles, a very small amount of ammonia was formed.

On analogy with certain other reactions peculiar to heterocycles, it might be expected that all of the heterocycles studied would be converted into cyclopentadiene. Our investigation, however, indicates that there is an essential difference between the oxygen- and sulfur-containing hydrogenated heterocycles on the one hand and the nitrogen-containing hydrogenated heterocycles on the other. In the given case the reaction of cyclopentadiene formation over a titania-alumina catalyst is of limited scope.

Owing to the absence of sufficient experimental material, it is not yet possible to state the true significance of the important fact that we have noted. However, on the basis of our results we may make an attempt to elucidate the mechanism of the formation of cyclopentadiene. There is no discussion of this matter in the literature, and the scheme that is generally applicable to the dehydration of ethers does not cover all of the products obtained in the reaction under consideration. In fact, if we were concerned with successive dehydration and dehydrocyclization reactions so that tetrahydro-2-methylfuran would first give piperylene, which would then undergo dehydrocyclization into cyclopentadiene:

then the yield of cyclopentadiene obtained by passage of piperylene over the same catalyst should be greater than that obtained from tetrahydro-2-methylfuran. The behavior observed, however, is the reverse. Moreover, kinetic measurements show that cyclopentadiene and piperylene are formed as the result of reactions that occur in parallel. Hence, the reaction being catalytic, it would appear that adsorption of tetrahydro-2-methylfuran on the catalyst surface forms a complex that reacts with formation of both compounds:

Experiment indicates that the nature of the catalyst is an important factor in the process, the extent of conversion being determined, therefore, by an energy factor.

SUMMARY

1. An investigation was made into the possibility of the formation of cyclopentadiene from tetrahydro-2-methylfuran, tetrahydro-2-methylthiophene, 2-methylpyrrolidine, and piperidine in presence of a titania-alumina catalyst at 600° at low pressure.

2. It was shown that, under these conditions, only tetrahydro-2-methylfuran and tetrahydro-2-methylthiophene give cyclopentadiene, the yield being about 20%.

3. The main reaction undergone by piperidine and 2-methylpyrrolidine was dehydrogenation into pyridine and 2-methylpyrrole respectively. In addition, piperidine gave 5% of pyrrole.

4. It was shown that the formation of cyclopentadiene from tetrahydro-2-methylfuran over a titania-alumina catalyst occurs as a result of both parallel and successive reactions.

CONTACT-CATALYSIS REFINING OF TUIMAZIN GASOLINE

N.I. Shuikin and E.D. Tulupova

As is well known, straight-run Tuimazin gasoline – owing to its low quality, which results from the high content of n-alkanes and organically bound sulfur – cannot be used in automobile engines without being refined. In the present investigation we studied the possibility of improving the performance properties of Tuimazin straight-run gasoline by desulfurization and modification of composition in a two-stage contact-catalysis process.

In the first stage of the refining the catalyst used was aluminum chloride, which is known to effect simultaneously the desulfurization of the gasoline and the isomerization of the n-alkanes present into branched forms. In the second stage the desulfurized gasoline was submitted to Zelinsky dehydrogenational catalysis. In this process the cyclohexane hydrocarbons, both those present in the original gasoline and those formed by the isomerization of cyclopentane hydrocarbons, were converted into the corresponding aromatic hydrocarbons.

There are various references in the literature [1-4] to the ability of aluminum chloride to give complexes with various organic sulfur compounds, both aliphatic and aromatic. Other authors [5] have noted that the response of gasolines to TEL (tetraethyllead) additions is much greater after treatment with aluminum chloride. Zelinsky and Yuryev [6] showed that with the aid of aluminum chloride it is possible to effect almost complete desulfurization of gasoline containing 0.392% of organically bound sulfur. Similar results were obtained by Goldshtein and Semenova [7] for the aluminum chloride desulfurization of gasoline containing thiols, aliphatic sulfides, and thiophene. The occurrence of the isomerization of mono- and di-alkylcyclopentanes into cyclohexane hydrocarbons in presence of aluminum chloride was demonstrated by Nenitzescu and Cantuniari [8] and others [9]. This reaction was studied in detail by Turova-Polyak and coworkers [10]. As regards the isomerization of n-alkanes in presence of aluminum chloride, several review articles have appeared [11-13].

In determining the conditions for the refining of Tuimazin gasoline, we used aluminum chloride with the object of removing organically bound sulfur from the gasoline, converting five-membered cycloalkanes into six-membered cycloalkanes (which were subsequently dehydrogenated into aromatic hydrocarbons), and isomerizing n-alkanes into branched forms. The results of the investigation showed that the two-stage refining (reforming) of Tuimazin gasoline (boiling limit 200°, octane rating 37.5 without TEL and 59.6 with 1.5 ml of TEL) was able to raise the octane rating to 50 without TEL and to 71.6 with 1.5 ml of TEL. This improvement in the performance properties of the gasoline is to be attributed to complete desulfurization, aromatization of cycloalkanes, and isomerization of n-alkanes.

EXPERIMENTAL

The following samples of Tuimazin gasoline were submitted to the refining process: 1) the whole gasoline, boiling range 34-200°; 2) the gasoline after removal of the head fraction, boiling range 60-200°; and 3) the gasoline after removal of the heptane-methylcyclohexane fraction (91-103°). Removal of the head fraction was carried out with the object of avoiding its loss during the aluminum chloride treatment. Removal of the heptane-methylcyclohexane fraction had the object of determining the possibility of obtaining toluene by its catalytic dehydrogenation at 300°. The properties of the original samples of Tuimazin gasoline are given in Table 1.

The separation of the head and heptane-methylcyclohexane fractions was carried out with the aid of a 19-plate column. The head fraction, amounting to 10% of the gasoline, was purified from sulfur compounds by means of sulfuric acid (3% on the weight of the fraction) and was subsequently mixed with the refined part of the gasoline.

TABLE 1

Properties of the Original Samples of Tuimazin Gasoline

Sample No.	Gasoline	Boiling range (°C)	n_D^{20}	d_4^{20}	Content of aromatic hydrocarbons (% by wt)	Sulfur content (% by wt)	Octane rating by the motor method		
							without TEL	with 1 ml TEL	with 1.5 ml TEL

2	Gasoline without head fraction	60-200	1.4149	0.7418	8.0	0.08	–	–	–
3	Gasoline without 91-103° fraction	34-200	1.4122	0.7332	7.5	0.079	39.0	–	60

TABLE 2.

Characteristics of Samples of Refined Tuimazin Gasoline

Sample No.	Sample of refined gasoline	Yield after $AlCl_3$ treatment (% by wt)	Boiling range (°C)	n_D^{20}	d_4^{20}	Content of aromatic hydrocarbons (% by wt)	Octane rating by the motor method		
							without TEL	with 1 ml TEL	with 1.5 ml TEL
1	Whole gasoline after catalysis	–	47-200	1.4195	0.7460	22.0	40.0	62.0	–
2	Whole gasoline after treatment with $AlCl_3$ (6%) at 80° for 6 hrs.	97.8	40-200	1.4128	0.7335	8.5	40.5	60.0	64.0
3	Sample No. 2 after catalysis	–	48-200	1.4270	0.7579	28.0	44.0	64.0	67.0
4	Gasoline without 91-103° fraction after treatment with $AlCl_3$ under the same conditions	97.0	40-200	1.4127	0.7346	8.0	40.0	59.3	63.4
5	Sample No. 4 after catalysis	–	47-200	1.4232	0.7523	22.0	48.0	65.0	68.0
6	Gasoline without head fraction after treatment with $AlCl_3$ (10%) at 80° for 20 hours	96.3	60-200	1.4114	0.7392	8.0	–	–	–
7	Sample No. 6 after catalysis and admixture with the head fraction	–	42-200	1.4238	0.7491	25.0	50.0	–	71.6

Experimental Conditions and Procedure

The following factors were varied in the experiments on the treatment of gasoline with aluminum chloride: the amount of aluminum chloride was varied from 6% to 10%, the duration of reaction from 6 hours to 20 hours, and the temperature from 80° to 100°. In each experiment 500 g of the gasoline was taken. The experiments were carried out in a three-necked flask fitted with mechanical stirrer, reflux condenser, and ther-

mometer. The condenser was connected to a trap cooled with dry ice, and this was followed by a wash bottle containing plumbite solution. After the catalysis operation, the gasoline was separated from aluminum chloride, washed - first with water, then with 10% caustic soda, and finally with water - and then dried with calcium chloride. The loss of gasoline in this treatment was 3.5-4%.

The catalyzates were characterized by refractive index, density, boiling range, and content of aromatic hydrocarbons (sulfuric acid method). The content of sulfur compounds was determined by the lamp method (All-Union State Standard 17872-39), and octane ratings were determined with a Vokesh engine. The dehydrogenation of the gasoline was carried out in a flow apparatus of the usual type at 300-305° (when platinized charcoal was used) and at 310-315° (when Ni on Al_2O_3 + SiO_2 was used).

TABLE 3

Group Compositions of the Original and Refined Tuimazin Gasolines (by Aniline Point Method)

2	Ditto	8	6	86.0	40-112	1.3835	0.6751	11.2
3	"	6	8	88.0	40-112	1.3852	0.6753	12.0
4	"	6	12	85.0	41-112	1.3850	0.6755	12.5
5	Octane	6	8	90.5	43-146	1.3941	0.6965	11.0
6	Ditto	6	8	90.0	43-150	1.3948	0.6968	11.5

*In order to establish the structure of the heptane isomers we separated the 80-90° fraction from the combined isomerizate. Raman spectra measurements by M.I. Batuev showed that this fraction consisted mainly of 2,4-dimethylpentane, very small amounts of 2,2-dimethylpentane and 2,2,3-trimethylbutane also being present.

Catalysts. The catalysts used, (platinized charcoal containing 10% of platinum, and nickel on a silica-alumina mixture, 30% Ni) were prepared by the procedure developed by Shuikin and coworkers. The volume of reduced catalyst was 150 ml. The space velocity for the passage of the gasoline was taken to be 0.4 $hour^{-1}$. The variation in the activity of platinized charcoal during the dehydrogenation of gasoline is shown in the figure. In this reaction, the nickel catalyst differed from the platinized charcoal in having a somewhat lower stability, but it could be regenerated about nine times. After regeneration with air at 300° for 4-5 hours and reduction with hydrogen at 350°, the catalyst again acquired high activity (the extent of the dehydrogenation of cyclohexane was 95-90%). The extent of the isomerization of five-membered cycloalkanes into six-membered cycloalkanes was established by dehydrogenation of gasoline after the first stage of refining, a platinized charcoal catalyst (10% Pt) being used.

In the catalytic treatment the content of aromatics in this gasoline was raised from 8% to 28%. The increase in the content of aromatics attributable to isomerization of cyclopentanes into cyclohexanes was 6% (see

samples No. 1 and No. 3 in Table 2). The optimum conditions for this isomerization were found to be: duration of catalytic treatment 6 hours, amount of aluminum chloride 6% on weight of original gasoline, temperature 80°. Raising of the temperature to 100° in the treatment of gasoline in presence of aluminum chloride does not improve the quality of the treated gasoline.

Variation in the activity of platinized charcoal with time in the aromatization of Tuimazin gasoline. Control experiments with cyclohexane.

With increase in the time of contact and in the amount of aluminum chloride, there was an increase in the isoparaffin content of the gasoline and therefore in its octane rating, which was raised to 71.6 (see Table 2, sample No. 7), i.e. 12 points higher than that of the original gasoline. The properties of the samples of refined gasoline are given in Table 2.

It may be concluded from the results presented in Table 2 that the use of the two-stage process enables a high level of refining to be attained in the treatment of Tuimazin gasoline, this being the result of the aromatization of cycloalkanes, the partial isomerization of n-alkanes, complete desulfurization (which results in a higher response of the gasoline to additions of TEL), and the removal of cyclopentane hydrocarbons, which, beginning with ethylcyclopentane, have low octane ratings. It should be noted that one single portion of aluminum chloride can be used effectively in three operations. Experiment shows that the octane rating of the gasoline can be raised to 64 (with 1.5 ml of TEL), i.e. by 4.4 points, in the first stage of the refining. The change in the chemical group composition in the first stage of the refining is shown in Table 3.

Table 3 shows that, as a result of the isomerization of the cyclopentane hydrocarbons, the content of cyclohexane hydrocarbons in the gasoline may be increased by 8.9%.

The occurrence of the isomerization of the n-alkanes of the gasoline was confirmed in separate experiments on pure heptane and octane.

Isomerization of n-Alkanes in Presence of Aluminum Chloride

Isomerization experiments were carried out on pure heptane and octane, which were first distilled through a 28-plate column. They had the following constants, which were close to values reported in the literature [14]: heptane - b.p. 98.6° (corrected), n_D^{20} 1.3875; d_4^{20} 0.6843; octane - b.p. 126.0° (corrected), n_D^{20} 1.3970; and d_4^{20} 0.7020. The catalytic reaction was carried out at 100° at atmospheric pressure for 6-12 hours. The treatment of the heptane and octane isomerizates was similar to that described above. The contents of isoparaffins were determined by a method described by Moldavsky and Livshits [15]. The evolved gas was analyzed in an Orsat-Lunge apparatus; it consisted entirely of saturated hydrocarbons. The experimental conditions and the properties of the isomerizates are given in Table 4.

The data presented in Table 4 show that, with increase in the amount of aluminum chloride and in the time of contact, there is an increase also in the isoparaffin content of the isomerizate. A partial cracking of the hydrocarbons is also to be observed. When the "whole" gasoline was treated with aluminum chloride under our conditions, cracking occurred to such a small extent that the boiling range of the gasoline remained practically unchanged. Losses in the form of gas did not generally exceed 3.5-4%. The possibility cannot be excluded that the absence of cracking is to be explained by the suppression of the aggressive action of aluminum chloride that has not entered into complex formation by the complexes formed by part of the aluminum chloride with sulfur compounds [1] and aromatic compounds [16].

SUMMARY

1. It was shown that Tuimazin gasoline can be completely desulfurized by treatment with aluminum chloride (6-10%). When the fact that one portion of aluminum chloride can be used for three successive operations is taken into account, it is found that its consumption does not exceed 2-3.5% on the weight of gasoline.

2. It was established that the desulfurization was accompanied by simultaneous isomerization of cyclo-

pentanes into cyclohexanes (the content of cyclohexane hydrocarbons was increased by 8.9%) and of n-alkanes into isoparaffins (to the extent of 10-12%).

3. As the result of a two-stage refining process, the octane rating of the gasoline was raised to 71.6 (with 1.5 ml of TEL), i.e. 10 points higher than that of the original gasoline.

POLYMERIZATION AND COPOLYMERIZATION OF N-VINYL COMPOUNDS

COMMUNICATION 2. SOME CHARACTERISTICS OF THE COPOLYMERIZATION OF VINYL ACETATE WITH 9-VINYLCARBAZOLE AND THE PROPERTIES OF THE COPOLYMERS

S.N. Ushakov and A.F. Nikolaev

We have shown in a previous communication that the addition of 9-vinylcarbazole to vinyl esters greatly reduces the rate at which they polymerize [1]. Values found for the copolymerization constants r_1 and r_2 for vinylcarbazole and vinyl esters (the formic, acetic, propionic, and butyric esters) indicate that the activities of vinylcarbazole and the vinyl ester in the copolymerization reaction are greatly different. Vinylcarbazole is always the more active component. As knowledge of the copolymerization constants does not allow us to obtain a complete picture of the behavior of the mixture of monomers in the copolymerization reaction or to predict certain properties of the copolymer, we have now made a more detailed study of the system vinyl acetate–vinylcarbazole. In studying this system we also had the object of verifying our hypothesis concerning the dependence of the molecular weight of the copolymers on the rate of the copolymerization reaction in such systems. The procedure used for the copolymerization reaction and for the isolation and purification of the copolymers was described in the previous communication.

Effect of Temperature. The effect of temperature on the rate of copolymerization of vinyl acetate and vinylcarbazole was studied at 65°, 80°, and 100°. At each temperature 10-12 different ratios of components were examined. It will be seen from Fig. 1 that the rate of copolymerization rises with rise in reaction temperature for all component ratios. Whereas at 80° and 100° copolymerization was observed at all monomer ratios, at 65° it occurred only at certain ratios; when the mole percentage of vinylcarbazole in the original mixture was in the range 10-35, no copolymer formation was observed in the course of nine hours in presence of 0.5% of benzoyl peroxide. This result, which was observed for the first time, suggests a more critical attitude to certain statements concerning the absence of copolymerization for various monomer pairs [2, 3]. When copolymerization trials are being carried out, it is necessary to take the initial composition of the mixture, the temperature, the duration of the process, and the initiator concentration into account. When due account is taken of these factors and reaction conditions are suitably chosen, there can be no doubt that copolymers will be obtained from compounds previously considered to be incapable of forming copolymers.

Effect of the Initial Composition of the Mixture on the Composition of the Copolymer. The effect of the composition of the monomer mixture on the composition of the copolymer formed was studied for twelve different mixtures. All of the experiments were carried out at 100° in presence of 0.5% of benzoyl peroxide. The results are given in Table 1.

It will be seen from Table 1 that all of the copolymers are enriched in vinylcarbazole with respect to the initial mixture, but the extent of the enrichment falls as the vinylcarbazole content of the initial mixture increases.

Effect of the Benzoyl Peroxide Concentration. The effect of the concentration of benzoyl peroxide on the rate of copolymerization of vinyl acetate and vinylcarbazole was studied for three different monomer mixtures. All of the experiments were carried out for one hour at 100°. The benzoyl peroxide concentration was varied from zero to 2%. The results are given in Table 2, and it will be seen from this table and from Fig. 2 that with rise in the concentration of benzoyl peroxide the rate of copolymerization rises, the mean rate being proportional to the square root of the initial benzoyl peroxide concentration (the mean rate of the process is expressed as percentage conversion per hour).

In experiments carried out at a molar ratio of vinyl acetate to vinylcarbazole of 10:1 in absence of benzoyl

peroxide, no copolymer formation was observed in the first hour, whereas in systems of high vinylcarbazole content (molar ratios of 2 : 1 and 1 : 1) some copolymer had already formed within the first hour. The amount formed increased with increase in the vinylcarbazole content of the initial mixture.

Solubility. The solubilities of vinyl acetate-vinylcarbazole copolymers of various compositions were determined in thirteen solvents. Solubility was determined qualitatively as follows: 10 ml of solvent was poured over 10 mg of the substance in a test tube, and the system was kept for 24 hours at 20°; the copolymer was considered to be soluble when a homogenous solution was obtained. It was found that all of the copolymers were soluble in dioxane, chloroform, and benzene, but insoluble in petroleum ether. Copolymers having low contents of vinylcarbazole (up to 30 mole-%) were soluble also in acetone, ether, carbon tetrachloride, and

ethyl acetate, whereas copolymers having vinylcarbazole contents of up to 10 mole-% were soluble in methanol, ethanol, and acetic acid. A comparison of the dissolving powers of solvents for vinyl acetate-vinylcarbazole copolymers was carried out as follows [4]: 50 mg of the copolymer was dissolved in 2 ml of solvent, and the solution was "titrated" with nonsolvent (petroleum ether) at 20°. The end point was determined by comparison of the turbidity formed with the turbidity of a standard sample prepared by mixing 2 ml of 0.001 N $AgNO_3$ with 1 ml of N NaCl acidified with nitric acid. The number of milliliters of petroleum ether required was taken to be the precipitation value. This method made it possible at the expense of very little material, to find the variation of the solubilities of the copolymers with composition and to show which were the best solvents. The results are given in Fig. 3. It was found that dioxane and chloroform are the best solvents for vinyl acetate-vinylcarbazole copolymers.

Intrinsic Viscosity of Copolymer Solutions. In the viscosimetric determination of molecular weight, the most comprehensive and satisfactory relationship that has yet been found is $[\eta] = kM^a$ [5], in which $[\eta]$ is the intrinsic viscosity, k is a coefficient which is constant in a given polymer homologous series in a given solvent, and a is a quantity that characterizes the form of the macromolecule in solution. The value of a depends on the flexibility of the chains and varies from 0.5 to 2.

The intrinsic viscosity of a polymer solution depends on the nature of the solvent, but for a given solvent it rises with increase in the molecular weight of the polymer. Although the viscosimetric method does not enable us to obtain absolute values for the molecular weights of polymers of various classes (since the values of k and a are not known) – particularly of copolymers – nevertheless, the method does enable us to compare and characterize macromolecular substances. In our viscosity study we used solutions of vinyl acetate-vinylcarbazole copolymers in benzene at concentrations of 0.2, 0.4, and 0.8 g per 100 ml of solvent. Immediately before the measurements the solutions were filtered through a No. 2 glass filter to remove small specks. The measurements were carried out in an Ostwald viscometer at 20°. The temperature in the 30-liter thermostatic water bath was maintained constant within ± 0.001° with the aid of a contact thermometer and electronic relay of the type designed by Sochevanov

[6]. The dimensions of the capillary of the viscometer were selected so that the time of flow for benzene was not less than 90 seconds. Each measurement was repeated at least five times, and only those results which agreed within 0.2 second were taken into account. In order to keep a check on the cleanliness of the capillary, control measurements were made on pure benzene at definite intervals of time. Values of reduced viscosity (η_{sp}/c) were graphed against concentration, and the curves were extrapolated to zero concentration in order to give the intrinsic viscosity $[\eta]$ [7].

Fig. 4 shows that an addition of even a small amount of vinylcarbazole (about 20 mole-%) to vinyl acetate greatly reduces the molecular weight of the reaction products. All of the copolymers of vinyl acetate and vinylcarbazole have lower intrinsic viscosities than that of polyvinylcarbazole prepared under the same conditions. Our experimental results are in accord with the suggestion that we made [1] concerning the lowering of the molecular weight of the reaction products in the copolymerization of monomers of the vinylcarbazole type with vinyl esters.

Vitrification Temperature. The vitrification temperatures of vinyl acetate-vinylcarbazole copolymers of various compositions were determined by the dilatometric method, in which the point of inflection (T_v) is determined on the curve for volume against temperature. The compressed sample (1 g) was placed in a tube, which was then connected through the ground joint at its open end to a capillary 50 cm in length and 0.5 mm in internal diameter. The dilatometer was evacuated, and then filled with mercury up to a definite level in the capillary. In order to determine the volume as a function of temperature, the dilatometer was placed in a thermostat heated at a rate of 1° per minute over a period of five minutes. In the succeeding five minutes the temperature was maintained constant, and the height of the mercury column in the capillary was then read. The results of these experiments are shown in Fig. 5.

Fig. 5 shows that for vinyl acetate-vinylcarbazole copolymers the vitrification temperature varies with composition. The introduction of a little vinylcarbazole (3-10 mole-%) results in a lowering of T_v below that of polyvinyl acetate, whereas copolymers of low vinyl acetate content have vitrification temperatures that are even higher than that of polyvinylcarbazole.

It is known that the proportion of polar groups and atoms present in the polymer molecule, the nature of these groups, and the possibility of more or less close packing determine the forces of interaction between the macromolecular chains. Polyvinyl acetate contains the polar groups $-OCOCH_3$ having a molecular cohesion of 5600 cal/mole, and polyvinylcarbazole has nonpolar carbazole groups having a high molecular cohesion on account of the large number of $=CH-$ groups present in the molecule. Moreover, the polyvinylcarbazole molecules are arranged so that interaction must occur between the planes, and not the edges, of the hexagons, and the bonding energy is very high. Polyvinylcarbazole, therefore, has a higher vitrification temperature than polyvinyl acetate.

The lowering of the vitrification temperature of copolymers containing only a small amount of vinylcarbazole may be explained by a loosening of the packing of the chains and a reduction of the forces of interaction between chains arising from the introduction of large vinylcarbazole molecules into the polyvinyl acetate chains. The forces of interaction between carbazole groups do not then make up for the lowering of the energy of dipole linkages ($-OCOCH_3$) between chains.

The rise in the vitrification temperature of copolymers containing only a small proportion of vinyl acetate molecules is probably to be explained by steric effects that prevent the complete interaction of the carbazole groups of the polyvinylcarbazole chains. On this account the introduction of a few acetic ester groupings into the polyvinylcarbazole molecule will facilitate the rotation of monomer units about carbon-carbon bonds and lead to a more complete approach of the planes of the carbazole groups of the chains. The consequence of this is a rise in the vitrification temperature. Similar rises in the vitrification temperatures of copolymers, as compared with those of the homopolymers, was observed by Margaritova and Raiskaya [8] for the systems butadiene-dinonyl maleate and butadiene-dinonyl fumarate.

SUMMARY

1. A study was made of the effect of the initial ratio of components, the reaction temperature, and the initiator concentration on the rate of the copolymerization of vinyl acetate and vinylcarbazole.

2. Vinyl acetate-vinylcarbazole copolymers of various compositions prepared at 100° were characterized. It was shown that the solubilities, molecular weights, and vitrification temperatures of copolymers prepared under identical conditions are dependent on composition.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 91. TRANSARYLATION OF BIBENZYL AT VARIOUS TEMPERATURES

G. S. Kolesnikov and V. V. Korshak

We have previously shown that, in presence of aluminum chloride, bibenzyl and other diarylalkanes undergo a linear-polycondensation reaction, which we have called transarylation [1-3]. We considered that it was desirable to determine the main laws governing this reaction, and therefore undertook a more detailed study of the transarylation of bibenzyl. We selected bibenzyl for study because in this case the probability of the occurrence of an intramolecular cyclization reaction is practically zero and the course of the main process will therefore not be distorted by it, as it might be in the transarylation of, for example, diphenylmethane. In the present paper we present our results on the transarylation of bibenzyl at various temperatures.

The experimental procedure was as follows. A weighed amount of bibenzyl was placed in a test tube provided with a side tube and was heated in a bath of glycerol or Wood's metal, which was maintained at a constant temperature. The tube was closed with a stopper through which passed a thermometer and a bubbling tube that reached almost to the bottom of the test tube. When the bibenzyl reached the desired temperature and was found to undergo no further change in the course of 15-20 minutes, finely ground aluminum chloride was introduced into the tube, care being taken to prevent the aluminum chloride from falling on the sides of the tube. Immediately after this addition, the stopper with the thermometer and bubbling tube was replaced and dry nitrogen was passed through the reaction mixture at 40 ml/minute. The side tube of the reaction vessel was connected to a water-cooled condenser and a receiver graduated accurately within 0.1 ml. The reaction time was reckoned from the time when the aluminum chloride was added to the bibenzyl.

Fig. 1. Transarylation of bibenzyl at various temperatures: 1 - 80°; 2 - 90°; 3 - 100°; 4 - 105°.

After the addition of aluminum chloride the reaction mixture immediately darkened and foamed as a result of the evaporation of the benzene formed; the bulk of the benzene collected in the receiver in the first 20-40 minutes. At the end of the prearranged period for the particular experiment, the test tube was taken from the heating bath, dilute hydrochloric acid and benzene were added as quickly as possible, and the contents of the test tube were transferred quantitatively to a separating funnel with the aid of benzene. The aqueous layer was separated from the benzene solution, which was washed several times with water and dried with calcium chloride. The calcium chloride used for drying was washed with two small portions of dry benzene, and this benzene was added to the main benzene solution. Benzene was distilled off, bibenzyl was distilled off under reduced pressure, and the residue was weighed.

When, apart from soluble poly(ethylenephenyl), an insoluble three-dimensional polycondensation product was formed, the contents of the reaction vessel were transferred quantitatively to a conical flask, and the whole mixture was filtered through a sintered-glass filter under suction. The insoluble product was washed with benzene until the washings were no longer colored, and it was then dried and weighed. The washings were added to the filtrate, which was treated as indicated above.

In order to determine the effect of temperature on the rate of the transarylation of bibenzyl, four series

Fig. 2. Effect of temperature on the rate of the transarylation of bibenzyl.

Fig. 5. Transarylation of bibenzyl at 140°.

Fig. 6. Transarylation of bibenzyl at various temperatures.

Fig. 7. Effect of reaction temperature on the molecular weight of poly(ethylenephenyl).

of experiments were carried out at various temperatures. In all the experiments of these series the aluminum chloride concentration was constant at 6.8 mole-%. In the experiments of a given series the temperature was kept constant. The results of these experiments are presented in Tables 1-4 and Fig. 1. The rate constants for the transarylation reaction were calculated from the usual formulas:

$$K_1 = \frac{2.303}{t} \log \frac{a}{a-x}$$

$$K_2 = \frac{1}{t} \cdot \frac{x}{a(a-x)},$$

in which a is the maximum yield of poly(ethylenephenyl) that is theoretically possible (on the assumption that each bibenzyl molecule is converted into $-C_6H_4CH_2CH_2-$) (in basal moles); x is the amount of poly(ethylenephenyl) formed (basal moles); and t is time (seconds). The dimensions of the second-order rate constant will be $sec^{-1}mole^{-1}$, for each basal mole of poly(ethylenephenyl) formed corresponds to one mole of bibenzyl that has undergone reaction.

In the separation of the reaction products we isolated the unchanged bibenzyl, but part of it was lost owing to incomplete condensation during distillation. We were therefore obliged to have recourse to the units of measurement indicated above.

It will be seen from Tables 1-4 that the transarylation reaction is governed by the laws of a second-order reaction. At 90°, 100°, and 105°, the rate constant calculated for a first-order reaction diminishes with time; at 80° this "constant" is indeed constant, probably because of the low concentration of growing chains at this temperature, which results in a quasiunimolecular reaction. Moreover, the poly(ethylenephenyl) formed probably reacts with benzene, which is somewhat difficult to remove from the reaction mixture at 80°. At 80° the second-order rate constant rises at first and then remains constant. At 80°, for times not less than 30 minutes, the mean second-order constant is $13.5 \cdot 10^{-3}$, and for 90°, 100° and 105° the mean second-order constants are $21.5 \cdot 10^{-3}$, $31.5 \cdot 10^{-3}$, and $40.0 \cdot 10^{-3}$, respectively. On the basis of these values, the temperature coefficients of the reaction rates are:

The molecular weight of the poly(ethylenephenyl) formed in the transarylation of bibenzyl in presence of aluminum chloride depends on the reaction temperature. It will be seen from Tables 1-4 and Fig. 3 that raising of the transarylation temperature results in a rise in the molecular weight of the poly(ethylenephenyl), which is not very noticeable in the early stages of reaction, but is quite obvious in the later stages. From Tables 1-4 and Figures 1 and 3 it can be seen also that the rise in the molecular weight of poly(ethylenephenyl) is more rapid in the second half of the process than the rise in the

TABLE 5

180	71.8	24.5	3130

actual yield of poly(ethylenephenyl). This indicates, that in addition to the gradual rise in the molecular weight of the poly(ethylenephenyl) resulting from its reaction with bibenzyl, products of higher molecular weight are formed by reaction of poly(ethylenephenyl) molecules among themselves.

In order to determine the variation of molecular weight in the course of the transarylation of bibenzyl at higher temperatures, we carried out a series of experiments at 140° in presence of 6.8 mole-% of aluminum chloride. The results are given in Table 5 and in Figures 4 and 5.

It will be seen from Table 5 and Figures 4 and 5 that at 140° the transarylation of bibenzyl results in the formation of soluble poly(ethylenephenyl) and an insoluble, infusible, three-dimensional polycondensation product, the yield of which rises with increase in the duration of the reaction. It is interesting to note that the molecular weight of the soluble poly(ethylenephenyl) rises rapidly at first, attains a maximum value, and then immediately begins to fall; simultaneously the yield of three-dimensional polycondensation products rises. In our opinion, this fall in molecular weight is to be explained by the removal of the longest linear molecules, which participate preferentially in the cross-linking that results in the formation of the three-dimensional products; as we have shown previously [4], the probability of branching, and therefore the probability of participation in the formation of three-dimensional molecules, rises with increase in the length of the molecules of

linear condensation products.

We studied also the effect of temperature on the molecular weight of the transarylation products from bibenzyl over the range 90-180° for a constant aluminum chloride concentration of 6.8 mole-% and a constant duration of reaction of five hours. The results are given in Table 6 and Figures 6 and 7.

Table 6 shows that rise of transarylation temperature results in the formation of three-dimensional product, the yield of which rises with rise in temperature. The molecular weight of the soluble poly(ethylenephenyl) increases at first, attains a maximum of 150°, and then rapidly diminishes (Fig. 7). In our opinion, this fall in molecular weight is due to the formation of three-dimensional products from the poly(ethylenephenyl) of highest molecular weight. It is quite probable that at 160-180° the poly(ethylenephenyl) of highest molecular weight reacts simultaneously with the polycondensation products of lower molecular weight and with the bibenzyl that has not yet reacted. As a result of these reactions, the molecular weight of the soluble poly(ethylenephenyl) falls.

SUMMARY

1. The transarylation of bibenzyl in presence of aluminum chloride was studied at various temperatures.

2. It was found that the transarylation of bibenzyl is subject to the laws of a second-order reaction, the activation energy being 11,400 ± 500 cal/mole.

3. It was shown that, in the transarylation of bibenzyl, chain growth occurs not only as a result of the reaction of poly(ethylenephenyl) with bibenzyl, but also as a result of the reaction of poly(ethylenephenyl) molecules among themselves.

MACROMOLECULAR COMPOUNDS

COMMUNICATION 92. EFFECT OF CATALYST CONCENTRATION ON THE TRANSARYLATION OF BIBENZYL

G.S. Kolesnikov and V.V. Korshak

In our previous communication we showed the effect of temperature on the transarylation of bibenzyl and we established that this reaction is subject to the laws of a second-order reaction [1]. We had previously shown that the aluminum chloride concentration is not a matter of indifference in the polycondensation of 1,2-dichloroethane with benzene, and it would be expected that in the transarylation of bibenzyl the aluminum chloride concentration would again affect the course of the process and the molecular weights of the reaction products [2]. In the present paper we give the results of experiments carried out with the object of verifying this supposition.

Fig. 1. Transarylation of bibenzyl at different aluminum chloride concentrations: 1 - 3.4 mole-%; 2 - 6.8 mole-%; 3 - 10.2 mole-%; 4 - 13.6 mole-%.

TABLE 1

Transarylation of Bibenzyl at an Aluminum Chloride Concentration of 3.4 mole-%

Duration of reaction (minutes)	Yield of poly(ethylenephenyl) (%)	$K_2 \cdot 10^3$	Molecular weight of poly(ethylenephenyl)
10	36.3	8.7	—
20	51.6	8.1	1430
30	59.9	7.6	1520
60	78.3	9.1	1640
80	81.4	8.3	1660

In order to determine the effect of catalyst concentration on the rate of the transarylation of bibenzyl, four series of experiments were carried out at 90° for different concentrations of aluminum chloride. The results are presented in Tables 1-4 and Fig. 1. As it has already been established [1] that the transarylation of bibenzyl is governed by the laws of a second-order reaction, only second-order constants were calculated. The experimental procedure was the same as before [1].

The mean values of the rate constants for the transarylation of bibenzyl at aluminum chloride concentrations of 3.4, 6.8, 10.2, and 13.6 mole-% are $8.4 \cdot 10^{-3}$, $21.5 \cdot 10^{-3}$, $32.9 \cdot 10^{-3}$, and $46.9 \cdot 10^{-3}$ respectively. These results show that the rate constant for the reaction is directly proportional to the concentration of the catalyst, aluminum chloride (Fig. 2).

It will be seen from Tables 1-4 and Fig. 3 that the molecular weight of the poly(ethylenephenyl) rises with increase in the catalyst concentration and the rise in molecular weight in the second half of the process is more rapid than the increase in yield. This indicates that the formation of poly(ethylenephenyl) proceeds not

Transarylation of Bibenzyl at 140° with Various Amounts of Catalyst

Catalyst concentration (mole-%)	Yield (%)		Molecular weight of soluble poly(ethylenephenyl)
	of soluble poly(ethylenephenyl)	of three-dimensional poly(ethylenephenyl)	
3.4	65.6	—	1520
6.8	58.6	13.1	10100
13.6	60.4	18.4	8580
20.4	56.9	24.9	6460
27.2	63.9	25.8	5790

Fig. 2. Effect of the aluminum chloride concentration on the rate of the transarylation of bibenzyl.

Fig. 3. Effect of the aluminum chloride concentration on the molecular weight of the poly(ethylenephenyl): 1 - 3.4 mole-%; 2 - 6.8 mole-%; 3 - 10.2 mole-%; 4 - 13.6 mole-%.

only as a result of reaction between growing poly(ethylenephenyl) molecules and bibenzyl, but also as a result of reaction of poly(ethylenephenyl) molecules among themselves [1].

Fig. 4. Transarylation of bibenzyl at 140°.

Fig. 5. Transarylation of bibenzyl at 140°: 1 - total yield; 2 - yield of three-dimensional product.

With the object of determining the effect of catalyst concentration on the molecular weight of poly(ethylenephenyl) formed in the transarylation of bibenzyl at a higher temperature, a series of experiments was carried out at 140° with varying amounts of catalyst, the duration of the reaction being kept constant for four hours. The results are presented in Table 5 and Figures 4 and 5.

It will be seen from Table 5 and Fig. 4 that, with increase in catalyst concentration, the molecular weight of the poly(ethylenephenyl) increases rapidly at first, but later there is a lowering of the molecular weight of the soluble poly(ethylenephenyl) with simultaneous increase in the yield of three-dimensional poly-(ethylenephenyl). The formation of three-dimensional transarylation products occurs mainly at the expense of the poly(ethylenephenyl) of highest molecular weight.

SUMMARY

A study wasmade of the effect of aluminum chloride concentration on the rate of the transarylation of bibenzyl and on the molecular weight of the poly(ethylenephenyl) formed.

SYNTHESIS AND REACTIONS OF CHLORO(2-METHYLALLYL)SILANES

A.D. Petrov and G.I. Nikishin

In recent papers by Petrov and Mironov [1] and Petrov and Nikishin [2], the organomagnesium synthesis of some methyl(2-methylallyl)- and trichloro(2-methylallyl)silanes were described. On the other hand, the direct synthesis of chloro(2-methylallyl)silanes has not yet been studied, though some papers have appeared relating to the direct synthesis of other alkenylsilanes. Hurd [3] prepared vinyl- and allyl-chlorosilanes, and Petrov and Sadykh-Zade [4] prepared a whole range of chloro compounds containing one and two silicon atoms.

The direct synthesis of chloro(2-methylallyl)silanes would be of no less interest, if only because of the valuable properties which, according to the patent literature [5], are possessed by organosilicon polymers derived from monomers containing 2-methylallyl radicals. Among the products that we have prepared in the present investigation of the direct synthesis of chloro(2-methylallyl)silanes in a total yield of 40%, trichloro-(2-methylallyl)silane $Cl_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$ predominated; the synthesis therefore differs in this respect from that of chloroisobutylsilanes, in which dichloroisobutylsilane $Cl_2HSiCH_2-\underset{\displaystyle CH_3}{\underset{|}{CH}}-CH_3$ predominated. The isolation of pure chloro(2-methylallyl)silanes was rendered difficult by the presence of diene hydrocarbons of similar boiling point; 2,5-dimethyl-1,5-hexadiene, formed evidently, by the combination of free 2-methylallyl radicals and partially isomerized under the conditions of the synthesis into 2,5-dimethyl-2,4-hexadiene.

Contrary to our expectations, attempts to methylate $(CH_3)_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$ with excess of methylmagnesium chloride or iodide were unsuccessful. The main product was hexamethyldisiloxane, and only when methylmagnesium chloride was used was $(CH_3)_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$ obtained also, the yield being only 3%:

$$Cl_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2+CH_3MgI\xrightarrow{H_2O}(CH_3)_3Si-O-Si(CH_3)_3$$

and

$$Cl_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2+CH_3MgCl\xrightarrow{H_2O}$$

$$\rightarrow (CH_3)_3Si-O-Si(CH_3)_3+(CH_3)_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$$

A less direct method for the synthesis of $(CH_3)_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$ from $Cl(CH_3)_2SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$ and excess of methylmagnesium chloride (though a smaller excess than in the case of $Cl_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$) gave the desired compound as the main product, although again the replacement of methyl chloride by methyl or ethyl iodide resulted in the isolation of only siloxanes:

In the reaction of methylmagnesium iodide with trimethyl- and triethyl-(2-methylallyl)silanes, the main products of the subsequent hydrolysis were siloxanes (obtained in 42% and 70% yield, respectively).

and

In the case of triethyl(2-methylallyl)silane, the 2-methylpropene that was isolated was identified in the form of 1,2-dibromo-2-methylpropane. When $(C_2H_5)_3SiCH_2-CH=CH_2$ was treated with methylmagnesium iodide and the product hydrolyzed, breakdown at the Si-C link did not occur and allyltriethylsilane was recovered unchanged. It is interesting to compare these results with those of Petrov and Shchukovskaya [6] on the reaction between phenyllithium and $(C_6H_5)_3SiCH_2-CH=CH_2$, which proceeds as follows:

Hence, with respect to their effectiveness in attacking allylsilanes, we may place the nucleophilic reagents studied in the following order: $C_6H_5Li > CH_3MgI > CH_3MgCl$.

In order to make a further study of condensation reactions with RMgX, we then carried out the chlorination of $Cl_3SiCH_2-C(CH_3)=CH_2$ in the hope that the main reaction would be Lvov-Tishchenko anomalous chlorination. Our hopes were realized: in addition to the dichloride (which underwent β-breakdown), a monochloro compound was also obtained:

Methylation of this monochloro derivative with methylmagnesium chloride occurred without breakdown at the Si-C linkage:

Hence, the strength of the Si-C linkage with respect to the action of nucleophilic reagents is lower in $(CH_3)_3Si-CH_2-C(CH_3)=CH_2$ than in $(C_2H_5)_3SiCH_2CH=CH_2$ and $(CH_3)_3SiCH_2-C(CH_2Cl)=CH_2$. The strengthening of the Si-C bond by the introduction of chlorine into the 2-methylallyl radical is probably to be explained by a reduction in the polarity of the Si-C bond, which approaches the C-C bond in character and becomes inert both to

products of the hydrolysis of Grignard reagents and also to the reagents themselves.

It should be noted that, as shown in separate experiments, boiling with 5% or 10% aqueous caustic potash does not break the Si-C bond in triethyl(2-methylallyl)silane. Hence, the above-mentioned breakdown of this compound with formation of 2-methylpropene is not due to the action of alkaline hydrolysis products. It is evident that the Grignard reagent and the alkenylsilane form some sort of complex, which is hydrolyzed by water.

EXPERIMENTAL

Chloro(2-methylallyl)silanes. 2-Methylallyl chloride was passed at 30 g per hour through a glass tube (length 600 mm, diameter 40 mm) filled with pieces of Si-Cu alloy (80% Si, 20% Cu) and mounted in an electric tube furnace, which maintained the temperature at 330 ± 10°. The reaction products were condensed with a water condenser. From 906 g (10 moles) of 2-methylallyl chloride, 726 g of condensate was obtained, and fractionation of this through a column (1100 mm in height, and filled with glass rings, 3 mm in diameter) gave the following fractions:

Fraction	I, B.p	30-100°; 114 g;	15.7%
Fraction	II, B.p	100-115°; 8 g;	1.1%
Fraction	III, B.p.	115-122°; 95 g;	13.2%
Fraction	IV, B.p.	122-135°; 23 g;	3.1%
Fraction	V, B.p.	135-140°; 166 g;	22.8%
Fraction	VI, B.p.	140-207°; 34 g;	4.7%
Fraction	VII, B.p.	207-213°; 32 g;	4.4%
	Residue	137 g;	18.9%

When refractionated, Fractions III, V, and VII yielded, respectively: dichloro(2-methylallyl)silane, trichloro(2-methylallyl)silane, and dichlorobis-2-methylallylsilane (for properties see Table), and also small amounts of 2,5-dimethyl-1,5-hexadiene (b.p. 113-114°; n_D^{20} 1.4314) from Fraction III and of 2,5-dimethyl-2,4-hexadiene (b.p. 133.5°; n_D^{20} 1.4738) from Fraction V. The total yield of chloro(2-methylallyl)silanes was 40%, i.e. was less than the yield of allylchlorosilanes obtained by Hurd [3], namely 60%.

Methylation of $Cl_3SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$. A stream of methyl chloride was passed through 700 ml of ether containing 40 g (1.64 moles) of magnesium until the whole of the metal had disappeared. Trichloro(2-methylallyl)silane, amounting to 72 g (0.38 mole), was added to the resulting organomagnesium compound. The mixture was boiled for five hours and then decomposed with water. Fractionation of the dried ethereal solution gave 12.2 g (39.5%) of hexamethyldisiloxane (b.p. 97-101°; n_D^{20} 1.3778; d_4^{20} 0.7623) (the literature [7] gives b.p. 99-100°; n_D^{20} 1.3771; d_4^{20} 0.7638) and 1.5 g (3%) of trimethyl(2-methylallyl)silane, b.p. 110.5-112°; n_D^{20} 1.4195; d_4^{20} 0.7436. When methyl iodide was used, only hexamethyldisiloxane could be isolated.

Methylation of $Cl_2HSiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$. All the succeeding methylations of various chloro(2-methylallyl)silanes with methyl chloride or iodide were carried out under identical conditions with excess of CH_3MgX. Reaction of 29 g (0.186 mole) of dichloro(2-methylallyl)silane and methylmagnesium chloride prepared from 8.24 g (0.75 mole) of magnesium gave 8.5 g (40%) of dimethyl(2-methylallyl)silane, b.p. 91-95°. In this synthesis no siloxane was obtained.

Preparation of $Cl(CH_3)_2SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$. A mixture of 64.5 g (0.5 mole) of dichlorodimethylsilane and 8 g (0.75 mole) of 2-methylallyl chloride was added over a period of six hours to 24.32 g (1 mole) of magnesium in 1.2 liters of ether. When the addition was complete, the mixture was boiled for four hours. The precipitate was filtered off, and fractionation of the ethereal solution gave 33.4 g (44.9%) of chlorodimethyl(2-methylallyl)-silane, b.p. 130-134°, and 7.6 g (9%) of dimethylbis-2-methylallylsilane, b.p. 176-179° and n_D^{20} 1.4556. The properties of chlorodimethyl(2-methylallyl)silane are given in the table.

Methylation of $Cl(CH_3)_2SiCH_2-\underset{\displaystyle CH_3}{\underset{|}{C}}=CH_2$. Reaction between methylmagnesium chloride, prepared from

8.08 g (0.33 mole) of magnesium, and 25 g (0.17 mole) of chlorodimethyl(2-methylallyl)silane yielded 8.1 g (40%) of trimethyl(2-methylallyl)silane, b.p. 111-112° (see table). A very small amount of hexamethyldisiloxane (5%) was obtained. When methylmagnesium iodide was used, only hexamethyldisiloxane (b.p. 97-100°, n_D^{20} 1.3779; d_4^{20} 0.7633; yield 55%) was obtained.

Found %: C 45.63; H 11.17
Calculated %: C 44.4 ; H 11.17

Ethylation of $Cl(CH_3)_2SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$. Reaction between ethylmagnesium iodide, prepared from 7.3 g (0.3 mole) of magnesium, and 22.3 g (0.15 mole) of chlorodimethyl(2-methylallyl)silane gave 4.6 g (32%) of a product boiling over the range 149-151° (n_D^{20} 1.4008; d_4^{20} 0.7972). For $C_2H_5(CH_3)_2Si-O-Si(CH_3)_2C_4H_7$ the literature [8] gives b.p. 148° (751); n_D^{20} 1.4014; d_4^{20} 0.7995. No silahydrocarbons were obtained.

Chlorination of $Cl_3SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$. The chlorination of 83 g of trichloro(2-methylallyl)silane was carried out in ultraviolet radiation in the apparatus described by Ponomarenko and Moronov [3]; the treatment was continued until the boiling point of the liquid in the flask attained 176° (8 hours 15 minutes). Fractionation of the reaction mixture yielded 10 ml of silicon tetrachloride (b.p. 58-60°), 8 ml of 2-methylallyl chloride (b.p. 70-72°; n_D^{20} 1.4280), 31.5 g of unchlorinated trichloro(2-methylallyl)silane, and 19.1 g of a substance boiling at 187.5-189.5° and obtained in 31.5% yield on the amount of trichloro(2-methylallyl)silane that reacted. The properties of the product are given in the table.

Methylation of $Cl_3SiCH_2-\underset{\underset{CH_2Cl}{|}}{C}=CH_2$. This structure is ascribed to the product on the basis of the known mechanism of the chlorination of 2-methylpropene and of the chlorination of 2-methylallyl chloride [10], in which $ClCH_2-\underset{\underset{CH_2}{|}}{C}-CH_2Cl$ was obtained. Reaction between methylmagnesium chloride prepared from 10 g (0.41 mole) of magnesium, and 18 g (0.08 mole) of $Cl_3SiCH_2-\underset{\underset{CH_2Cl}{|}}{C}=CH_2$ gave 7.75 g (59.5%) of [2-(chloromethyl)allyl]trimethylsilane, b.p. 160-164°, the properties of which are given in the table.

The structure of $(CH_3)_3SiCH_2-\underset{\underset{CH_2Cl}{|}}{C}=CH_2$ (I) was confirmed also by a study of its Raman spectra, which was carried out by Egorov. The presence of the lines 1415, 1631, and 3087 cm^{-1} indicated the terminal position of the C=C bond [11, 12]. The choice, therefore, can be only between formulas (I) and $(CH_3)_3SiCHCl-\underset{\underset{CH_2}{|}}{C}=CH_2$ (II). This coice suggests a comparison with the spectrum of $(CH_3)_3SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$ (III). In this last compound frequencies of 1396 and 1415 cm^{-1} are present and the C=C frequency is 1 38 cm^{-1}. In the monochloro compound under investigation frequencies in the range of 1380-1395 cm^{-1} are absent and the C=C frequency is lowered to 1631 cm^{-1}. Since the 1380-1395 cm^{-1} frequencies belong to a CH_3 group at a C=C bond, preference must be given to the form (I), in which such a group does not occur; moreover, this structure explains the lowering of the C=C frequency (effect of the chlorine atom).

Reactions of $(CH_3)_3SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$; $(C_2H_5)_3SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$ and $(C_2H_5)_3SiCH_2-CH=CH_2$ with Methylmagnesium Iodide. 7.45 g of trimethyl(2-methylallyl)silane, 22 g of triethyl(2-methylallyl)silane, or 12 g of allyltriethylsilane was added to ethereal methylmagnesium iodide (prepared from 3.12, or 6 g of magnesium, respectively). There were visible signs of reaction. The ether was distilled off, and the residue was heated at 70-85° for 7-8 hours. In the case of $(C_2H_5)_3SiCH_2-\underset{\underset{CH_3}{|}}{C}=CH_2$, the internal space of the apparatus was connected to the atmosphere through a trap cooled by a mixture of dry ice and acetone. The trap remained empty during the whole time of heating. The flask was cooled, the ether that had been distilled off was added, and the contents of the flask were decomposed with water. In the first case 2 g (42%) of hexamethyldisiloxane (b.p. 102-104°,

n_D^{20} 1.3917; d_4^{20} 0.7628)was isolated from the ether layer, and in the second case 11.3 g (70%) of hexaethyldisiloxane (b.p. 232-233°, n_D^{20} 1.5088; d_4^{20} 1.7670) was isolated. The liquid that collected in the trap during decomposition of the reaction mixture rapidly absorbed bromine, and the dibromide so formed (11% yield) had the following properties: b.p. 152°, n_D^{20} 1.5088, and d_4^{20} 1.7670; these properties correspond to 1,2-dibromo-2-methylpropane. The allyltriethylsilane was recovered unchanged after the operation.

SUMMARY

1. The direct synthesis of chloro(2-methylallyl)silanes was carried out for the first time. A total yield of 40% was obtained, and trichloro(2-methylallyl)silane accounted for more than half of this.

2. It was shown that in trialkyl(2-methylallyl)silanes the Si-C bond is more resistant to the action of Grignard reagents than in allylsilanes.

3. Lvov-Tishchenko anomalous chlorination of trichloro(2-methylallyl)silane was carried out for the first time, and it was shown that the introduction of a chlorine atom into the 2-methylallyl radical strengthens the Si-C bond and makes it incapable of being broken down under the action of Grignard reagents.

ACTION OF DILUTE NITRIC ACID ON ISOLATED LIGNIN

A.A. Chuksanova, L.L. Sergeeva, and N.N. Shorygina

The first investigations on the action of dilute nitric acid on lignin were associated with the question of the delignification of raw material of vegetable origin. Very little study has been devoted to the nitration of isolated lignin with dilute nitric acid. There is a reference to the oxidation of "hydrochloric acid" lignin with hot dilute nitric acid, which was found to result in a loss of methoxyl groups and an increase in the content of acidic groups [1]; oxalic acid was formed simultaneously. Hachihama and Oshishi [2], who treated lignin isolated from sugar cane with 5% nitric acid at 100°, obtained a nitro product containing 3-4% of nitrogen.

It is known that heating of vegetable raw materials with dilute nitric acid not only nitrates the lignin, but also brings about the partial breakdown of the lignin molecule. Nitrated monomers are formed in small amount. Thus, the Japanese chemists Hachihama and Oshishi [2], in their treatment of sugar cane with dilute nitric acid, found that the following substances were present in admixture with the nitrolignin: 4-hydroxy-3--nitrobenzaldehyde, 4-hydroxy-3-nitrobenzoic acid, and 4-hydroxy-3,5-dinitrobenzaldehyde. K. Shinra and J. Shinra [3] isolated 4-hydroxy-3-nitrobenzaldehyde from the liquid obtained by the digestion of Graminaceae with nitric acid.

We considered it to be of interest to study the nitration of isolated lignin with dilute nitric acid at the boil.

EXPERIMENTAL

Samples of "hydrochloric acid" and "hydrolysis" lignins were used in the experiments. The "hydrochloric acid" lignin was isolated from pine chips by means of fuming concentrated hydrochloric acid, sp. gr. 1.21, in accordance with Willstätter's method. The "hydrolysis" lignin of the Leningrad Hydrolysis Works was ground in a ball mill, extracted with water, extracted twice with dichloroethane, and dried - first in the air, and then over phosphoric oxide. The composition of the "hydrochloric acid" lignin was C 60.30%; H 6.25%; OCH_3 15.50%. The composition of the "hydrolysis" lignin was C 62.78%; H 5.79%; OCH_3 10.00%. Nitration was effected with 3%, 5%, and 7% nitric acid at the boil.

A stirred mixture of 10 g of lignin and 400 ml of 3% nitric acid was heated to the boil. When boiling began the mixture was heated for a further 15-180 minutes. The first experiments did not give positive results: the lignin remained unchanged. In later experiments it was observed that when stirring was switched off during the heating of the reaction mixture oxides of nitrogen were rapidly formed and the whole mass then foamed up. After 20-30 minutes the foaming ceased. It is to be noted that the formation of oxides of nitrogen during the heating did not depend on the temperature, but generally occurred at 70-80°. It was frequently observed that the addition of sodium nitrite hastened the onset of reaction, whereas in presence of ammonium nitrate nitration of lignin by dilute nitric acid did not take place.

In this way nitrolignins were obtained in the form of light-yellow powders, which could be readily filtered off and washed with water. The filtrates, which were of a pale-brown color, contained mainly oxalic acid. The composition of the nitrolignin obtained from "hydrochloric acid" lignin was C 54.14%, H 4.75%. The composition of the nitrolignin obtained from "hydrolysis" lignin was C 49.67%, H 4.28%.

All of the samples were analyzed for nitrogen, methoxyl, and carboxyl contents. Methoxyl groups were determined by Zeisel's method. Carboxyl groups were determined by Purves' method [4]. The results are given in the table.

TABLE

Expt. No.	Nitrating agent*	Reaction temperature (°C)	Time after coming to boil (minutes)	Yield of nitrolignin (% of original)	Nitrogen content (%)	OCH_3 content (%)**	COOH content (%)***	Notes
			"Hydrochloric Acid" lignin					
1	3% HNO_3	98	15	99.90	1.89	–	3.07	Evolution of oxides of nitrogen was observed
2	Ditto	98-99	30	99.20	2.02	10.90	2.77	Ditto
3	"	98-99	60	92.90	1.98	10.70	3.67	"
4	"	98-100	180	89.60	2.27	10.00	4.51	"
			"Hydrolysis" lignin					
1	3% HNO_3	99.5	15	80.20	2.86	4.00	4.88	"
2	3% HNO_3 with addition of $NaNO_2$	98	15	70.27	3.05	5.70	4.84	"
3	7% HNO_3	96	15	80.80	2.55	3.50	4.49	"
4	Ditto	96	15	80.80	2.50	–	4.47	"
5	5% HNO_3	98	15	82.56	2.32	–	4.33	"
6	3% HNO_3	100	30	92.30	0.32	10.00	1.38	No oxides of nitrogen were evolved

* Bath ratio 1:40 for 3% HNO_3 and 1:20 for 7% HNO_3.
** OCH_3 content of "hydrochloric acid" lignin 15.3%, and of "hydrolysis" lignin 10.00%.
*** COOH content of "hydrochloric acid" lignin 0.68%, and of "hydrolysis" lignin 0.66%.

As will be seen from the table, in the experiments in which no evolution of oxides of nitrogen was observed, no nitration occurred and the lignin remained almost unchanged. In all of the experiments in which oxides of nitrogen were formed, nitration of the lignin occurred. The nitrogen content of the nitrolignins was 2-3%. The nitration of lignin was accompanied by partial loss of methoxyl groups: a loss of 24-30% for "hydrochloric acid" lignin, and a loss of 38-62% for "hydrolysis" lignin.

In all of the experiments in which oxides of nitrogen were formed, oxidation of the nitrolignin occurred with the formation of carboxyl groups. It is possible that the number of carboxyls formed was considerably greater, since the reaction conditions facilitated decarboxylation.

From the nitrolignins obtained we were able to isolate 4,6-dinitroguaiacol (Chemical Abstracts numbering) in 0.82% yield in the following way. Dry nitrolignin prepared under the conditions described above (100 g; nitrogen content 2-3%) was extracted in the cold with ether. The ether extract was dried, and the ether was distilled off. The dry residue, amounting to 1.80 g, was a pale-brown crystalline mass. Recrystallization from ethanol yielded 4,6-dinitroguaiacol, m.p. 122.5°, undepressed by admixture with synthetic 4,6-dinitroguaiacol.

Found % N 12.74
$C_7H_6O_6N_2$. Calculated % N 13.08

SUMMARY

1. A study was made of the nitration of "hydrolysis" lignin with dilute nitric acid (3%, 5%, and 7%) at the boil.

2. It was shown that under these conditions the nitrating agent was oxides of nitrogen. The nitrogen content of nitrolignins obtained under these conditions does not exceed 3.0%.

3. When lignin is nitrated with dilute nitric acid at the boil, the methoxyl content diminishes and the carboxyl content increases.

4. From the nitration products from "hydrochloric acid" and "hydrolysis" lignins oxalic acid was isolated, and also 4,6-dinitroguaiacol in 0.32% yield.

BRIEF COMMUNICATIONS

CONDENSATION OF FERROCENE WITH ALDEHYDES

A.N. Nesmeyanov and I.I. Kritskaya

The publication of work by Weinmayr [1] on the condensation of ferrocene (dicyclopentadienyliron) with aldehydes prompted us to publish our results in this field, which were included in a paper read by A.N. Nesmeyanov at the Fourteenth International Congress on Pure and Applied Chemistry in June 1955, but which did not constitute a finished investigation.

The aromatic properties of ferrocene, which are evident in sulfonation reactions [1], in arylation reactions with diazo compounds [2], in acylation with acid anhydrides, acid chlorides, and silicoanhydrides of acids, and in metallation, including mercuration [3], are manifested also in its condensation with aldehydes. We have found that, in presence of concentrated sulfuric acid, ferrocene is able to react with aqueous formaldehyde and also with benzaldehyde. Reaction proceeds readily and rapidly at 65-75° and gives 65-75% yields of condensation products. The products contain two ferrocene nuclei, and they correspond in composition to dimethylenediferrocene and dibenzylidenediferrocene $(C_5H_4)_2$ $Fe(CHR)_2$ $Fe(C_5H_4)_2$, in which R = H or C_6H_5. In the reaction of ferrocene with benzaldehyde, the substance $(C_5H_4)_2$ Fe [$CH(C_6H_5)$] [CH (OH) (C_6H_5)] Fe (C_5H_4) (C_5H_5) is also obtained. The benzaldehyde reaction products differ in melting point; they differ also in their solubilities in acetone, and it was therefore possible to separate them. All of the reaction products were obtained in the oxidized form as ferricinium derivatives, and they were isolated in the crystalline state by reduction with stannous chloride.

For the same condensation Weinmayr employed anhydrous hydrofluoric acid, which is much less convenient. Moreover, in the reaction with benzaldehyde he obtained a single substance, to which he attributed two greatly differing melting points. According to our results, the two melting points correspond to two different substances.

All of our products are readily crystallized from dioxane and benzene and are less readily crystallized from acetone. They are orange in color and are oxidized after long standing in the air. Work on these compounds will be continued.

EXPERIMENTAL

Dimethylenediferrocene. A mixture of 7.2 g (0.04 mole) of ferrocene and 1.2 g (0.04 mole) of formaldehyde (4.2 g of a 40% aqueous solution) was cooled to − 15°, and it was stirred while 50 ml of 96% sulfuric acid, also cooled to − 15°, was added rapidly. Stirring with cooling was continued for 15 minutes; the mixture was then stirred further for 30 minutes at room temperature and for 1 hour 15 minutes at 65-75°. The solution, which was at first reddish brown, gradually became green. The reaction mixture was cooled to room temperature and poured into 250 ml of water. The black precipitate that formed was filtered off; it contained traces of unchanged ferrocene and probably also products of far-reaching oxidation of the molecule. Concentrated hydrochloric acid (30-40 ml) was added to the filtrate, and then stannous chloride in small portions. As soon as the first portions of stannous chloride were added, a precipitate began to form which, toward the end of the reduction, became pure yellow in color. The addition of the reducing agent was continued until the green color of the solution disappeared, and the mixture was then set aside at room temperature for two hours. The precipitate was filtered off, washed - first with water acidified with hydrochloric acid, and then with pure water - and dried. The precipitate was found to be soluble in benzene, chloroform, and dioxane - less soluble in acetone and alcohol; it could be purified by shaking the benzene solution with alumina and recrystallization from dioxane.

It melted at 191° in a sealed capillary. The yield was 65-75%. Its molecular weight, determined cryoscopically in benzene, was 377, the value calculated for dimethylenediferrocene being 398.

Found %: C 66.45; 66.62; H 5.57; 5.68; Fe 27.13; 27.02
$C_{22}H_{22}Fe_2$. Calculated %: C 66.71; H 5.09; Fe 28.20

The substance oxidized in the air.

Dibenzylidenediferrocene. This substance can be prepared and isolated under the same conditions. A mixture of 14.4 g (0.08 mole) of ferrocene and 4.24 g (0.08 mole) of benzaldehyde was prepared under cooling, and it was then heated at 65-70° for 90 minutes. The precipitate was reduced, washed, and dried, and the product was heated with successive portions of acetone until the solution obtained was almost colorless. The acetone solution contained dibenzylidenediferrocene together with traces of ferrocene. The dibenzylidenediferrocene was purified by shaking the acetone solution with alumina and recrystallization from dioxane or acetone. The melting point of dibenzylidenediferrocene was 218-220° (sealed capillary). The total yield of condensation products was 12.4-16.2 g (60-75%). The mixture of products contained about 50% of dibenzylidenediferrocene.

Found %: C 74.14; 73.91; H 5.71; 5.91; Fe 20.05; 19.80
$C_{34}H_{28}Fe_2$. Calculated %: C 74.47; H 5.14; Fe 20.37

The acetone-insoluble part of the precipitate was crystallized from dioxane or benzene (the solution was first shaken with alumina, which adsorbed oxidation products). It melted at 268-270° (sealed capillary). The product was probably an intermediate compound containing one hydroxy group.

Found %: C 72.50; 72.46; H 5.70; 5.82; Fe 19.82; 19.80
$C_{34}H_{30}Fe_2O$. Calculated %: C 72.11; H 5.34; Fe 19.73

When allowed to stand for a long time in the air, all three substances darken and acquire an impurity that is adsorbed by alumina, i.e. are oxidized.

SUMMARY

1. The reaction of ferrocene with aliphatic and aromatic aldehydes was studied.

2. It was shown that, in presence of concentrated sulfuric acid, ferrocene reacts with formaldehyde and with benzaldehyde with formation of a dimethylenediferrocene and dibenzylidenediferrocene, respectively. In the reaction with benzaldehyde a compound corresponding in composition to $(C_5H_4)_2$ Fe $[CH(C_6H_5)]$ $[CH(OH)(C_6H_5)]$ Fe $(C_5H_4)(C_5H_5)$ was also obtained.

DIPOLE MOMENTS OF ALKYL 2-DIALKYLAMINOVINYL KETONES

A.N. Shidlovskaya, Ya.K. Syrkin, and N.K. Kochetkov

We have measured the dipole moments of some members of a class of unsaturated amino compounds $RCOCH = CHNR_2'$ synthesized by Kochetkov [1]. The polarities of these compounds may serve as a criterion for the conjugation of the carbonyl bond with the unshared electron pair of the nitrogen via the double bond. The shift of electrons may be represented by the formula:

As a result of the increase in the negative charge on the oxygen, the weakening of the double-bond character of the C=C bond, and the increase in the positive charge on the nitrogen, a considerable dipole moment should arise. It is of interest to compare the results of a physical method with the chemical behavior of these substances.

Dielectric constants were determined by the heterodyne-beat method in benzene solution at 25°. The refractions R_D were measured by Kochetkov. It is interesting that departures from additivity of 4-5 cc were here detected. Values of the total polarization P_∞, the refraction R_D, and the dipole moment μ are given in Table 1.

TABLE 1

Substance	P_∞	R_D	$\mu \cdot 10^{18}$
2-Diethylaminovinyl methyl ketone $CH_3COCH = CHN(C_2H_5)_2$ (I)	715.40	47.26	5.67

The conjugation of the carbonyl group with the C=C double bond has almost no effect on the value of the moment, as can be seen from the example of mesityl oxide, the moment of which is 2.8 D, i.e. approximately the same as the moment of acetone. Three N–C bonds give a total moment of not more than 0.9 D. Evidence has recently appeared which indicates that the urea molecule is flat [2], i.e., the C–N and N–H bonds are arranged as if sp^2-hybridization occurred as a result of the existence of a strong internally ionized state. It is possible that this occurs also in our case. If that is so, then the three bonds will be mutually inclined at 120° and their moments will neutralize each other. In any case, in addition to the moment of the carbonyl bond the compounds have a considerable supplementary polarity on account of the conjugation with nitrogen. This is in accord with their chemical behavior. They are unable to undergo the diene synthesis, probably owing to the weakening of the double bond character of the C=C bond. Moreover, the Grignard reaction does not occur at the carbonyl group. The dipole-moment results do not provide an unequivocal answer to the question of cis or trans structure owing to the nonfeasibility of calculating from the vector sum of individual bonds in this case.

The difference between the moments of the substances (III) and (IV) indicates a small effect due to the alkyl group attached to the carbonyl. The substantial equality of the moments of (IV) and (V) indicates that further increase in the complexity of the alkyl group no longer affects the moment. The moments of the substances (I), (II), and (III) differ somewhat from one another. It would appear that groups attached to nitrogen have greater effects on the moment than groups attached to the carbonyl. Finally, we must point out that the dipole-moment results are in accord with the results of an investigation of the absorption spectra of these compounds [3].

SUMMARY

The dipole moments of five unsaturated amino compounds were measured. All of the substances were found to have considerable polarity. The enhanced polarity of these compounds is in accord with their chemical behavior.

CYANOETHYLATION OF TRICHLOROSILANE

A.D. Petrov, V.F. Mironov, V.M. Vdovin, and S.I. Sadykh-Zade

It has been shown in previous papers [1,2] that organosilicon alcohols, amines, and thiols readily add to acryonitrile when the functional groups are α or γ with respect to Si. Organosilicon compounds having the same functional groups on the silicon are cyanoethylated with great difficulty. In the present investigation we have succeeded in effecting the addition of trichlorosilane to acrylonitrile in presence of Raney nickel:

$$HSiCl_3 + CH_2 = CHCN \xrightarrow[\text{Raney nickel}]{} Cl_3SiCH_2CH_2CN.$$

This reaction is the first example of cyanoethylation at an Si–H bond. The yield of 3-(trichlorosily.)propionitrile was 12.2%, only a little lower than the yield obtained under the conditions of direct synthesis [3].

EXPERIMENTAL

Synthesis of $Cl_3SiCH_2CH_2CN$. A mixture of 80 g of freshly distilled trichlorosilane, 35 g of acrylonitrile, and 5 g of Raney nickel was prepared in an autoclave, which was then heated at 160-170° for four hours. The maximum pressure during the reaction did not exceed 20 atm. The autoclave was cooled, and the reaction product was filtered from catalyst and solid polymer. Three fractionations gave a fraction (14 g) boiling at 79-82° (10 mm); it solidified on standing to give crystals of m.p. 32-33°. The literature [3] gives b.p. 84-86° (10 mm) m.p. 33-34°.

Found %: Si 14.67; 15.05

$C_3H_4Cl_3SiN$. Calculated %: Si 14.85

Synthesis of $(CH_3)_2SiCH_2CH_2COCH_3$. A solution of 9 g of $Cl_3SiCH_2CH_2CN$ in 50 ml of absolute ether was added over a period of 15 minutes to a Grignard reagent prepared from 38 g of CH_3I. After the usual treatment a ketone having the following properties was isolated: b.p. 82-85° (65 mm); d_4^{20} 0.8339; n_D^{20} 1.4231. The same ketone prepared previously by Petrov, Sadykh-Zade, and Vdovin [3] from $Cl_3SiCH_2CH_2CN$ synthesized by the direct method had the following properties: b.p. 81.5-83° (64 mm), d_4^{20} 0.8325; n_D^{20} 1.4235. Sommer and Nelson indicate similar properties for this ketone: b.p. 84° (65 mm); d_4^{20} 0.8330; n_D^{20} 1.4228.

Under the above-described conditions, the cyanoethylation reaction went also when trichlorosilane was replaced by dichloromethylsilane, but we did not succeed in isolating pure $Cl_2(CH_3)SiCH_2CH_2CN$ by fractionation. Furthermore, we did not succeed in isolating this compound when Raney nickel was replaced by other catalysts (palladium on copper and platinum on charcoal).

SUMMARY

It was shown that 3-(trichlorosilyl)propionitrile can be synthesized by the addition of trichlorosilane to acrylonitrile in presence of Raney nickel.

DESTRUCTIVE HYDROGENATION OF 2-METHYLTHIOPHENE WITH HYDROGEN AT HIGH PRESSURE

M.G. Gonikberg, V.V. Kiseleva, and Ya.L. Goldfarb

One of us and Nikitenkov [1] has previously investigated the destructive hydrogenation of toluene in absence of catalysts at 455-490° with hydrogen under high pressure (up to 1350 atm). This process results in the formation of benzene and methane together with a small amount of high-boiling products, among which biphenyl and bitolyl were isolated and identified. The homogeneity of this reaction was shown both in the investigation cited [1] and also in the earlier investigation of Nemtsov and Levin [2]. At the highest pressures used (1100 and 1350 atm) a little methylcyclohexane was also detected among the reaction products, the formation of this substance being probably associated with the catalytic effect of the autoclave walls (stainless steel).

It was considered to be of interest to compare the behavior of toluene under the conditions of destructive hydrogenation in absence of catalysts with that of 2-methylthiophene. Moldavsky in collaboration with Prokopchuk [3] and Kumari [4] has investigated the destructive hydrogenation of thiophene in absence of catalyst at 230-450° in an autoclave, the initial hydrogen pressures ranging up to 80 atm. Apart from hydrogen sulfide, these authors established the presence of tetrahydrothiophene among the reaction products, and they suggested that the autoclave walls might have a catalytic effect. Fricke and Spilker [5] had previously investigated the noncatalytic hydrogenation of thionaphthene at 425-438° under working pressures of 110-160 atm. Among the reaction products they isolated and identified benzene, toluene, ethylbenzene, 2-ethylthiophene, 2,3-dihydrothionaphthene, and anthracene. There are no data in the literature on the noncatalytic destructive hydrogenation of alkylthiophenes.

The results obtained in the present investigation show that there are substantial differences between 2-methylthiophene and toluene with respect to the course of the process of destructive hydrogenation under high pressures of hydrogen.

EXPERIMENTAL

The 2-methylthiophene used in our experiments had the following constants: b.p. 111.5° and n_D^{20} 1.5203 (the literature [6] gives b.p. 112.5° and n_D^{20} 1.5203). The experiments were carried out in accordance with the procedure already described [1] in a stainless steel autoclave having a capacity, including that of the manometer, of about 100 ml. The initial hydrogen pressure was 500 atm. Below, we give the results of two experiments at 400°.

Experiment 1. Load: 20.00 g of 2-methylthiophene. Duration of experiment at working temperature: 4 hours. Working pressure: 1070-850 atm. Residual pressure: 370 atm. When the autoclave was unloaded, the gaseous products were passed through 20% NaOH solution in order to absorb hydrogen sulfide, the amount of sodium sulfide formed being determined iodometrically. The gas was found to contain 2.02 g of sulfur, i.e. 31% of the amount in the original 2-methylthiophene. No appreciable amount of hydrocarbons could be detected among the gaseous products after removal of hydrogen sulfide.

The colorless liquid unloaded from the autoclave (13.60 g*; n_D^{20} 1.4962) was then subjected to chromatographic separation on a silica-gel column. The following fractions were obtained:

*The unloading losses were generally about 2 g, but in the experiment described they were higher than this.

Fraction I,	1.50 g;	n_D^{20} 1.3793
Fraction II,	3.20 g;	n_D^{20} 1.5058
Fraction III,	4.25 g;	n_D^{20} 1.5113
Fraction IV	2.60 g;	n_D^{20} 1.4895

It was later found that Fraction I owed its low refractive index to the presence of pentane. In Fractions II and III neither thiophene nor tetrahydrothiophene could be found by fractional distillation. Fraction IV was again passed through silica gel, and 1.46 g of a substance having n_D^{20} 1.4872 was isolated. This fraction was then distilled twice from a Wurtz flask, and a fraction boiling at 126-128° was collected and found to have n_D^{20} 1.4878. It was found to be tetrahydro-2-methylthiophene, for which the literature [7] gives b.p. 131.5° (756 mm), 132.5° (750 mm); n_D^{20} 1.4922; 1.4886.

Found %: C 58.88; 58.62; H 9.92; 9.92; S 31.20; 31.16
$C_5H_{10}S$. Calculated %: C 58.83; H 9.80; S 31.37

Experiment 2. Load: 51.7 g of 2-methylthiophene. Time at working temperature: 3 hours 30 minutes. Working pressure: 1000-650 atm. Residual pressure: 210 atm. The gas was found to contain 5.64 g of sulfur, i.e. 33.5% of the amount in the original 2-methylthiophene. The 43.6 g of colorless liquid unloaded from the autoclave was fractionated through a 17-plate column having a glass packing. The following fractions were collected:

Fraction I, B.p. 31-42°;	1.72 g;	n_D^{20} 1.3638
Fraction II, B.p. 42-79°;	1.24 g;	n_D^{20} 1.4112
Fraction III, B.p. 79-88°;	0.76 g;	n_D^{20} 1.4590
Fraction IV, B.p. 88-111°;	2.76 g;	n_D^{20} 1.5032
Fraction V, B.p. 111-112°;	15.12 g;	n_D^{20} 1.5173
Fraction VI, B.p. 112-114°;	6.74 g;	n_D^{20} 1.5183
Fraction VII, B.p. 114-125°;	1.06 g;	n_D^{20} 1.5044
Fraction VIII, B.p. 125-136°;	1.08 g;	n_D^{20} 1.4945
Fraction IX, B.p. 136-155°;	1.42 g;	n_D^{20} 1.4919
Fraction X, B.p. 155-170°;	1.87 g;	n_D^{20} 1.4888
Residue	7.50 g.	

Fractions I, II, III, VII, and VIII were then chromatographed. Fraction I yielded pentane, n_D^{20} 1.3580 (the literature [8] gives n_D^{20} 1.3575).

Found %: C 83.16; H 16.89
C_6H_{12}. Calculated %: C 83.33; H 16.67

Fractions V and VI consisted mainly of uncharged 2-methylthiophene, as was shown by a further fractional distillation.

Our attempts to detect and isolate thiophene (b.p. 84.1°) from Fraction III and tetrahydrothiophene (b.p. 121.2°) from Fraction VII were not successful. The non-formation of the latter compound is probably due to the lower partial pressure of hydrogen in Experiment 2.

The residue remaining after the fractional distillation of the reaction products was vacuum fractionated. The following fractions were obtained:

Fraction XI, b.p. 95-96° (20 mm); M 162; C 72.71%; 72.41%; H 9.38%; 9.33%; S 17.81%; 17.89%.
Fraction XII, b.p. 116-117° (20 mm); M 169; C 73.40%; 73.56%; H 8.73%; 8.61%; S 17.73%.
Fraction XIII, b.p. 144-148° (20 mm); C 71.28%; 71.24%; H 7.51%; 7.49%; S 21.43%.

These data on the composition of the high-boiling reaction products and their molecular weights enables us to infer that they contain a mixture of compounds having one sulfur atom formed by the addition of hydrocarbon radicals containing five carbon atoms to 2-methylthiophene (possibly partially hydrogenated) or to the radical formed by the opening of its ring. In fact, compounds having the empirical formulas $C_{10}H_{18}S$ and $C_{10}H_{16}S$ should contain respectively, 71.5% and 73.2% of hydrogen and 9.5% and 7.3% of sulfur (molecular weights 185 and 184 respectively), which are fairly close to the analytical results for Fractions XI-XIII.

SUMMARY

1. Our results indicate that, under the conditions studied, there is a very great difference between the processes occurring in the destructive hydrogenation of toluene and of 2-methylthiophene. We were unable to detect thiophene, tetrahydrothiophene, or methane among the reaction products, and so were unable to establish the occurrence of the dealkylation of 2-methylthiophene. On the other hand, dealkylation is an essential feature of the destructive hydrogenation of toluene.

2. The destructive hydrogenation of 2-methylthiophene occurs at lower temperatures, i.e. more rapidly, than the destructive hydrogenation of toluene.

3. The pentane and tetrahydro-2-methylthiophene that we have isolated from products of the destructive hydrogenation of 2-methylthiophene form only an insignificant part of the 2-methylthiophene that reacted. Unlike toluene, which gives practically only benzene and methane when subjected to destructive hydrogenation, 2-methylthiophene gives a mixture of various products.

CURRENT EVENTS

CONFERENCE ON ELECTROCHEMISTRY AT THE POLISH ACADEMY OF SCIENCES

A conference on electrochemistry was held in the capital of the Polish People's Republic - Warsaw - on November 15-19, 1955. On the invitation of the Polish Academy of Sciences delegates from the Soviet Union and the People's Democracies (Czechoslovakia, Hungary, and the German Democratic Republic) took part in the work of the conference.

About forty papers were presented on various aspects of electrochemistry. Particular attention was paid to the role of the interfacial potential between phases in flotation and chromatographic processes, to the absorption of cathodic hydrogen by metals and its effect on mechanical and magnetic properties, to the theory of solutions, and to electrothermodiffusion.

At the first session Prof. M. Smialowski read a long paper entitled "Investigation of Electrochemistry in Poland, Past and Present". In Poland, work on electrochemistry began to develop shortly after the First World War. One of the centers of electrochemical research was the laboratory at the Jagiello University (Krakow), which in 1920 was directed by Prof. Bohdan Szyszkowski (1873-1931). In spite of the fact that Szyszkowski began his scientific work in the laboratory of the great organic chemist Reformatsky at Kiev, from the very beginning his work was essentially electrochemical. He worked on the relationship between the dissociation of organic acids and their molecular structures, and he later devoted his activities to the establishment of the laws of dissociation in weak electrolytes. Work in a similar direction was carried out by Marjan Hlasko (1921-1939) in Vilna University. Using a very accurate method of measurement, Hlasko made a systematic study of the conductivity and dissociation of various substances in aqueous and nonaqueous solutions. The speaker then discussed the work of Prof. Kazimerza Jablczynski of Warsaw University, who studied the theory of electrolytes, the kinetics of electrode processes, etching phenomena at electrodes, etc.

Prof. Smialowski discussed also the work of the eminent Polish scientist Prof. Smoluchowski, whose work on electrokinetic phenomena has been a stimulus for further investigators in this direction (that of G. Lyaksa in Warsaw, M.S. Glixelli and Prof. A. Galecki in Poznan, and particularly Prof. Kamiensky in Krakow). In treating polarography and polarographic methods of analysis, the speaker discussed the work of Wiktor Kemula, who began his scientific career in 1935 at Lvov University, but has recently worked in the Department of Inorganic Chemistry of Warsaw University.

Passing to a general appraisal of the development of electrochemistry in "old" Poland, Prof. Smialowski pointed out that a regrettable shortcoming was the absence of any close relationship between the subjects investigated and the needs of industry. The speaker stated that "the lines of work in our research institutes almost always followed - not always very successfully - those of West European research institutes, particularly German". Prof. Smialowski considered that the reasons for this lay in the lack of interest shown by investigators in industrial problems owing to the fact that the greater part of industry was in the hands of foreign capitalists, who not only did not submit any of their problems to the research institutes, but also refused to allow investigations to be carried out in the laboratories of the industrial concerns. The speaker cited examples showing how the American capitalists who owned the Polish zinc industry tried to prevent research from being carried out. He also gave interesting facts showing how foreign capitalists retarded the development of the electrochemical industry in Poland.

For example, American industrialists proposed to the Polish government that they should build a power station on the condition that they should receive the sum of 80 grosz per kw-hr, in spite of the fact that the cost of electricity at the power stations in Upper Silesia was 1.9 grosz per kw-hr.

In his concluding remarks Prof. Smialowski stated that after the Second WorldWar the electrochemical industry made extremely rapid progress in the Polish People's Republic, both quantitatively and qualitatively. Thanks to close cooperation with the Soviet Union and the People's Democracies, all the necessary conditions had now been

created for the rapid advancement of science in Poland.

At the first session, following Prof. Smialowski's address, a review paper was read by B.N. Kobanov (Moscow) on the effect of the specific adsorption of anions on the rate and mechanism of electrochemical processes. A distinction was drawn between the simple phenomenon of the establishment of an adsorption potential when ions are adsorbed at the surface of a dielectric and the complex phenomenon of the specific adsorption of ions at the interface between metal and electrolyte solution accompanied by the exchange of potential-determining ions between the phases. It was shown that, at metal and metal-like (oxide) electrodes, the specific adsorption of anions often leads to great changes in the rates of electrochemical processes, this being associated with change in the electrical structure of the electrode surface.

Papers were read also by B. Baranowski and his coworkers on the theory of diffusion and methods of measuring diffusion. In his paper, B.Baranowski, using Onsager's work, examined the thermodynamic theory of diffusion as applied to liquid alloys. The paper of J. Demichowicz and B. Baranowski was concerned with the electrothermodiffusion method of measuring the transfer of particles in aqueous electrolyte solutions, and it was shown that this method was to be preferred to the thermogravitational method.

M. Samowski and B. Baranowski presented a paper on the anomalous vapor pressure observed in certain three-component aqueous and nonaqueous solutions: in these systems the vapor pressure is considerably greater in concentrated solutions than in less concentrated solutions. Samowski and Baranowski referred to this anomalous behavior as "antiRaoultian". The authors consider that this anomaly is due to the formation of double salts or the interaction of ions with solvent molecules with formation of solvates of variable composition.

In a paper entitled "The Role of Hydrogen in the Electrodeposition of Metals" K.M. Gorbunova (Moscow) gave an exposition of the material that has led to the establishment of a relationship between the mechanical, magnetic, and optical properties of deposits, their structures, and their hydrogen contents. On the basis of a generalization of a large amount of experimental material, the speaker showed that it was necessary to distinguish a special group of deposits - an indistinctly crystalline type, which includes brilliant chromium, nickel, copper, and other deposits of practical importance. The mechanism of the formation of such deposits differs in principle from the mechanism of electrocrystallization, which is associated with periodic layer formation on the crystal faces. The absorption of hydrogen is regarded not as the cause of the strained state of the deposits, but as a consequence of the dislocation of the metal lattice owing to the incorporation of surface-active substances, including hydroxides forming at the cathode.

In his paper A.T. Vagramyan (Moscow) pointed out the part played by the nonuniformity of the cathode surface in the electrodeposition of metals; when account is taken of the presence of active sites on the electrode, it is possible to solve some problems of practical and theoretical importance.

Bogdan Kamienski (Krakow) read a paper on the role of the electrical potential arising at the phase interface in processes of adsorption, flotation, and chromatography. Kamienski's paper was supplemented by papers presented by his students. Thus, B. Waligora described the essential features of the potentiometric method of chromatography, which consists in the measurement of the variation of the potential of a micro-element as the effluent from an adsorbent column passes over it. The speaker gave various examples showing how the method made it possible to separate mixtures of pyridine derivatives, fatty acids, etc.

I. Kulavin noted still another characteristic property of the micro-electrode, namely its high sensitivity to gases. He showed that by making use of this fact it was possible to determine traces of certain gases and vapors (iodine, bromine, chlorine, hydrogen sulfide, and others) in air and in nitrogen. For example, the micro-electrode is sensitive to 0.00007% of chlorine in air.

A. Pomianowski gave an address on electrical phenomena accompanying flotation processes. He showed that the effect of the flotation reagent (xanthate) on the electrode potential is greater in acid solutions than in alkaline. A study of the effect of a "suppressor" (potassium dichromate) on the potential of the mineral, makes it possible to establish the optimum ratio between the concentrations of flotation reagent and "suppressor".

W. Kemula's paper was devoted to the chromatopolarographic method and its application to the investigation of inorganic and organic compounds. Kemula showed that this combined method opens up new possibilities for the investigation of the most varied types of chemical compounds.

S. Lingiel (Budapest) read a paper entitled "Investigation of the Distribution of Molecules and Aggregates in Electrolyte Solutions and Other Two-Component Solutions". Prof. Lani (Budapest) reported the results of work on phosphating carried out in his laboratory.

The conference listened also to accounts of the work of the M. Smialowski school (Warsaw) on the overvoltage of hydrogen, the mechanism of the cathodic absorption of hydrogen by metals, and the effect of hydrogen absorption on the mechanical properties of metals. A. Krupkowski and M. Smialowski's paper presented experimental results on the deformation of an iron wire resulting from the absorption of hydrogen during electrolysis. M. Smialowski presented a paper describing the effect of change in polarization conditions on the brittleness produced in iron and nickel under the influence of the absorbed hydrogen. It was observed, in particular, that in presence of arsenic the brittleness of iron polarized in sulfuric acid was considerably greater than in the absence of arsenic; in presence of dibenzyl sulfoxide, however, the brittleness was less. It was shown that the effect of cathodic hydrogen on the mechanical properties of nickel was considerably less than its effect on iron, this difference being explicable by the difference in the catalytic properties of these metals for the recombination of hydrogen atoms to form molecules. In J. Forist and M. Smialowski's paper it was shown that the brittleness is due to the accumulation of hydrogen at defects in the metal structure, i.e. at inclusions of oxides, sulfides, etc.

W. Palczewska read a paper on the effect of certain organic substances and catalytic poisons on the overvoltage of hydrogen at iron and nickel cathodes. G. Jarmolovicz analyzed the effect of catalytic poisons on the overvoltage of hydrogen and the yields obtained in the reduction of nitrobenzene, tungstic acid, and other substances. L. Kozlowski (Kliwice) gave a very thorough discussion of the theme "The Effect of Hydrogen Formed at the Cathode on the Magnetic Properties of Mild Steel". J. Koryta (Prague) read an interesting paper on electrode reactions investigated by the polarographic method, and J. Kuta (Prague) discussed the mechanism of the separation of hydrogen at mercury electrodes.

S. Minc (Warsaw) gave an interesting review paper on the work carried out under his supervision. The main theme of the paper was the investigation by optical methods (Raman and absorption spectra, refractometry) of the relationship between the structure of electrolytes and the nature of the medium. Lech Stolarczik discussed the use of absorption spectra in the study of the structures of complex compounds.

On the basis of the results of investigations on the structure of nitric acid, carried out with the aid of Raman spectra, Z. Kecki concluded, in his paper, that the nitration of aromatic compounds is brought about not only by the ion, but also by the undissociated molecule of nitric acid. He considers also that the process proceeds the more readily, the greater the polarization of the $HO-NO_2$ bond in the given medium and the lower the energy required for the removal of a proton from the aromatic compound. W. Libus read a paper on the solvation of copper and cobalt ions in water and in organic solvents, this being investigated with the aid of absorption spectra. G. Angerstein (Warsaw) described his work on the mechanism of the cathodic atomization of lead; he showed that alkali metals formed an alloy with lead at the surface of the lead cathode, and this alloy was the source of the atomization.

In conclusion we must mention that the papers received very thorough discussion, and we must emphasize particularly the active part taken by the younger people in this discussion. The work of the conference demonstrated the wide range covered by the research into theoretical and applied electrochemistry now being carried out in the Polish People's Republic. Such conferences, in which scientists of different countries take part, are extremely useful in promoting the extensive exchange of experience between scientists, and they will undoubtedly further the fruitful development of science.

Prof. A.T. Vagramyan

IN FURTHERANCE OF CONTINUING PROGRESS IN THE SCIENCE OF CHEMISTRY

The Twentieth Congress of the Communist Party of the Soviet Union has now completed its work. The resolutions passed at the Congress are of great historical importance: they lay down the program to be followed in the struggle for the establishment of a communist society in our country, for the consolidation of peace throughout the world, and for the triumph of the ideas of Marxism-Leninism.

The Congress heard and discussed the Report of the Central Committee of the Communist Party of the Soviet Union, which was read by the First Secretary of the Central Committee, Comrade N. S. Khrushchev. The Report of the Central Revisory Committee, which was read by P. G. Moskatov, was also discussed.

In approving the Report of the Central Committee of the Communist Party of the Soviet Union, the Twentieth Congress passed a resolution which expresses the collective views and wishes of the Party and which constitutes an extremely important program of action.

The Congress heard and discussed the Report of the Chairman of the Soviet of Ministers of the USSR, Comrade N. A. Bulganin, concerning the directives in the Sixth Five-year Plan for the development of the national economy of the USSR in 1956-60. The Congress ratified these directives. The Congress decided to make some modifications in the party statutes. It resolved also that, for the next party congress, a party program should be prepared which would reflect the basic principles of Marxist-Leninist theory, as creatively developed on the basis of the historical experience of our party and the experience also of the fraternal parties of the socialist countries and of all the other international communist and working-class movements. Consideration was given also to the long-term plan that has been prepared for the building of communism and the development of the economic structure and culture of the Soviet Union.

The Congress elected the central executive bodies of the Party.

In the Report of the Central Committee the Twentieth Congress of the Communist Party was presented with a close analysis of the present international situation. In this report, Comrade N. S. Khrushchev made a scientific summing up of achievements in national economy, state organization, and culture in the Soviet Union. In the years between the Nineteenth and Twentieth Party Congresses, the Lenin Central Committee has shown notable perspicacity in the assessment of the internal and external situations. N. S. Khrushchev's report reflects a creative fighting spirit applied to the grandiose tasks of building up a communist society.

The scientifically developed Marxist-Leninist theories of the peaceful coexistence of two systems, of the possibility of avoiding war in the present period, of the forms of transition to socialism in different countries, and of the attitude to be taken to social-democratic parties are of great fundamental importance. These important and theoretically bold conclusions, which are associated with the laws of social evolution and their application under present-day conditions, acquire the character of a program and are of great practical importance in determining the correct policy to be adopted in the next stages of building up a communist society.

In the resolution on N. S. Khrushchev's report the Congress noted with great satisfaction the further consolidation of the internal position of the Soviet Union. The resolution states that, as a result of the work of the Central Committee in consistently marking out the general party line, there has been a considerable rise in production in all branches of industry and agriculture, and a great improvement in the material well-being and cultural level of the people. The true basis of all socialist economics was, and still is, the preferential development of heavy industry. The determining factor in the further growth of our industry is continual technical progress. The Congress pointed out the special importance of the incorporation of the discoveries of science into the national economy. In an atmosphere of great political enthusiasm, the Congress carried a unanimous resolution registering its full approval of the line of policy and practical activities of the Central Committee of the Communist Party of the Soviet Union, and also of the practical propositions and conclusions contained in the report.

In Comrade N. A. Bulganin's report on the "Directives of the Twentieth Congress of the Communist Party of the Soviet Union relating to the Sixth Five-year Plan" and in the resolutions taken on this report, a picture was

given of the grand prospects before us in the further growth of our state. In the approved directives of the Twentieth Congress for the Sixth Five-year plan for the development of the national economy of the USSR in 1956-60, we are set tasks which are of the highest importance and require an enormous increase in the productive capacity of our country.

The directives state: "The performance of the principal tasks set by the Sixth Five-year Plan for the development of the national economy of the USSR demands, as a basis, the preferential development of heavy industry, continual technical progress, and rise in the productivity of labor so that there may be further rapid advances in all branches of the national economy and a rapid rise in agricultural production, the result being a considerable improvement in the material well-being and cultural level of the Soviet people." The fulfillment of this plan for the development of the national economy of the USSR in 1956-60 will be an important step in the solution of the main economic problem of the USSR — to draw level with and pass the most advanced capitalist countries in the production of the goods required to meet the needs of the people.

Grandiose, exacting tasks lie before Soviet chemists. It is sufficient to state that the volume of production set for the most important industrial products in 1960 — the last year of the Sixth Five-year Plan — is as follows: petroleum 135,000,000 tons (191% of the volume of production in 1955), gas 40 billions cu·m (almost four times as high as in 1955), mineral fertilizers 19,600,000 tons (twice as high as in 1955), and caustic soda 1,000,000 tons (177% of the volume of production in 1955).

One of the most important problems of the chemical and petroleum industries will be to bring about a sharp increase in the use of natural gases and petroleum products in the manufacture of synthetic alcohols, resins, and rubbers, high-quality soap substitutes, and synthetic materials for machine construction, radio technology, and other branches of the national economy.

The directives of the Twentieth Congress of the Communist Party of the Soviet Union with respect to the Sixth Five-year Plan point out the necessity for the development of science in all possible ways and the extension of theoretical investigations in all branches of knowledge. The part played by scientific institutes in the furtherance of technical progress and the organization of production must be extended. Much work has to be done by the scientific research institutes in bringing their activities closer to the actual needs of the national economy. In designing and planning organizations it is essential that the maximum use should be made of the achievements of Soviet and foreign science and technology. The efforts of scientists must be concentrated as much as possible on scientific problems of importance for the national economy. It is essential that the research institutes should be better provided with modern scientific equipment and that more of the scientists at the higher-education establishments should be drawn into scientific research.

Soviet chemists have great tasks before them in the development of work in various fields of great importance. A few of these tasks are outlined below.

Physical and Theoretical Chemistry. The study of the relationship between the structure and reactivity of compounds must be intensified. In this study questions of the mutual effects of atoms in molecules and the nature of the elementary chemical act in its relation to the structures of the reacting species (molecules, ions, radicals) and to the nature of the medium will be of great importance. In the first place elementary acts occurring in liquid-phase and heterogeneous reactions must be studied. It is necessary to make a quantitative study of the mechanism, kinetics, and stereochemistry of reactions in gaseous, liquid, and solid phases. In reactions of practical importance (cracking, oxidation-reduction reactions in the liquid phase, oxidation of organic substances, etc.) it is important to determine the identity and chemical properties of the active intermediate substances and to study the elementary stages in which they take part. Work on the solution of these problems in the theory of the chemical process must form the basis for the devising of effective methods of controlling the directions of chemical reactions.

Photochemistry. Much attention should be given to the effects of radiation on matter over a wide range of frequencies (from the infrared to the ultraviolet) — in particular, in their relation to the problem of photosynthesis. Apart from development in the biological direction, it is important to develop also the physicochemical side of photosynthesis. The field of photoluminescence, particularly the search for new luminophores, borders closely on this problem.

Theory of Catalysis and the Scientific Principles of the Selection of Catalysts. The development of this field is of great importance. The main tasks will consist in the determination of the relationship between the catalytic properties of substances and their compositions and structures, and also in the study of the kinetics and mechanisms

of catalytic processes used in various branches of industry, especially the chemical and petroleum-refining industries. There can be no disputing of the fact that investigations on catalysis must be carried out on the reactions of greatest practical importance.

Chemical Thermodynamics. Investigation must develop mainly in the direction of the study of the thermodynamic properties of chemical compounds. No less importance must be attached to work on the theory of aqueous and nonaqueous solutions, the main attention being turned to the study of nonaqueous solutions (metallic solutions, salt and oxide melts), which are of great importance for metallurgy.

Electrochemistry. Attention should be directed mainly to the theory of electrode processes (which forms the basis for work on new chemical sources of current), to methods of electrolysis, to the preparation of new types of deposits, and to the electrosynthesis of various organic compounds. These theoretical and experimental investigations will be important also for the solution of other chemical problems.

Inorganic Chemistry. Attention must be devoted mainly to the development of the chemistry of the individual elements, particularly the rare elements. The most important problems here are the discovery of methods of obtaining increased yields in the extraction of these elements and the preparation of the elements in a highly pure state. Special technical significance is attached to problems associated with the extraction of germanium, titanium, and zirconium, since in the near future the scale upon which these metals are used will be greatly extended.

In the Sixth Five-year Plan it is essential that there should be extensive study of the inorganic compounds of boron, fluorine, and silicon. It is essential to extend and intensify work on the synthesis and properties of metal peroxides, ozone derivatives, etc. Of no less importance is the task of intensifying the investigation of new salt-bearing deposits and developing the scientific principles underlying their utilization, particularly in districts in which rich salt deposits have recently been discovered (Belorussian SSR, Kazakh SSR, Kirgiz SSR, and some of the south-western districts of the USSR).

Analytical Chemistry. In this field, which is of special importance at the present time, the main task consists in the development of rapid, exact, automatic methods of analysis. Of no less importance will be accurate methods for the determination of small amounts, sometimes the merest traces, of impurity. It is essential to concentrate attention on the devising of new, and the perfection of existing, physicochemical methods of analysis (mass spectroscopy, radioactivation analysis, multichannel photoelectric spectroscopy, the use of ultrasonics and isotopes, etc.).

Apart from the development of analytical methods, it is necessary also to develop the theory of analytical chemistry, in particular the chemistry of substances in solution. Studies must be made of the processes occurring in the separation of substances by the methods of chromatography, extraction, fractional distillation, etc.

Geochemistry. Investigators are faced by a series of problems relating to the laws determining the distribution, transfer, and concentration of elements in different geological processes. The solution of these problems will greatly facilitate the scientific, geochemical direction of the search for new ore deposits.

The main directions of scientific research in geochemistry during 1956-60 must lie both in the development of physical and physicochemical methods for the investigation of mineral raw material and also in the extension of investigations on the geochemistry of isotopes with the object of determining the absolute age and origin of useful ore deposits.

Organic Chemistry. One of the most important theoretical problems of organic chemistry is the establishment of the relationship between structure and reactivity. In the further development of organic chemistry important parts must be played by physical methods, the methods of chemical kinetics, optical methods (in various frequency regions – from the infrared to the far ultraviolet), X-ray, electron, and neutron diffraction, mass spectroscopy, radiospectroscopy, methods of studying magnetic and electrical properties, etc. The application of stable and radioactive isotopes must be substantially developed. The solution of various theoretical problems and problems of computation demands a great intensification of studies in quantum chemistry.

The development of organic chemistry should proceed in the following main directions:

The development of synthetic methods and routes of synthesis for the intermediate and ultimate products of chemical industry (plastics, synthetic fibers, rubbers, solvents, toxic chemicals, growth-promoting substances,

synthetic detergents, new fuels, etc.). The raw materials for these syntheses must be petroleum, cracking gases, and industrial and natural gases. The main method of synthesis must be the catalytic method.

The synthesis and wide application in new technical uses of organic compounds containing silicon, fluorine, nitrogen, phosphorus, aluminum, boron, and other elements.

The investigation of new physiologically active compounds and proteins isolated from animals and plants, and the synthesis of these compounds or their analogs with the object of utilizing them in various fields of the national economy.

The development of methods of synthesis of macromolecular compounds, and the establishment of the relationship between the properties of these compounds and their structures.

In conclusion, it must be emphasized that chemistry must be developed from all sides. This is required by the directives of the Twentieth Congress of the Communist Party of the Soviet Union relating to the Sixth Five-year Plan. Only then can we expect to obtain a "point of growth". It is essential also to develop the theory of chemical structure and the chemical kinetics of gas and liquid reactions, quantum chemistry, and chemistry of rare elements, radiochemistry, the chemistry of natural compounds, particularly proteins, and other fields. The great variety and wide applicability of various physical and physicochemical methods of investigation will assist greatly in the further progress of chemistry.

Great tasks are set by the directives of the Twentieth Congress of the Communist Party of the Soviet Union with respect to the Sixth Five-year Plan for the development of the national economy of the USSR in 1956-60. Our scientists, working creatively hand in hand with the Soviet people, will advance science still further in the cause of the welfare and prosperity of our Fatherland.

Armed with the great, vital teaching of Marxism-Leninism, and closely consolidated around the Lenin Central Committee, the Communist Party boldly guides our country forward toward the complete triumph of communism.

THERMODYNAMICAL INVESTIGATIONS OF WETTING PHENOMENA

A. V. Dumansky

(Paper read at a General Meeting of the Division of Chemical Sciences of the Academy of Sciences of the USSR, October 28, 1955)

1. Colloidal systems have come to be regarded — particularly after the investigations of Wolfgang Ostwald and Freundlich — as polyphase systems containing clearly defined interfaces. The theory of surface phenomena has therefore acquired great importance for colloid science. Lyophilic character in dispersed systems has been investigated from the point of view of surface energy, numerous detailed studies having been carried out since the beginning of the century. Knowing the specific surface and assuming the presence of a unimolecular layer, one may readily calculate the amount of liquid adsorbed per unit area of the surface, a quantity that can be used to characterise the lyophilic character of the system.

Important investigations on surface phenomena have been carried out in the USSR, particularly in the laboratories of B. V. Ilyin, M. M. Dubinin, and A. V. Kiselev. Detailed reviews of work carried out here and abroad can be found in the books of Kiselev [1], Adam [2], Rideal [3], Dubinin, Ilyin, and others.

All these discussions of lyophilic character can be applied more or less rigorously only to systems in which the dispersed phase forms a strictly defined interface with the dispersion medium. Most lyophilic colloids (colloidal systems based on macromolecular compounds) do not possess clearly defined interfaces associated with their micelles, molecular aggregates, and individual molecules, and it is sometimes doubtful whether they can be said to possess any surface intermicellar energy. From these considerations it will be seen that the study of the lyophilic character of colloidal systems on the basis of the concept of surface energy is not always possible, except in the case of suspensoids — although, even in this case, it is not always possible to identify surface tension and free surface energy [4].

Two quantities — the heat of wetting of unit mass of colloid and the amount of medium (e.g. water) sorbed by this mass — are characteristic of all colloidal systems and are more or less readily measured directly. These two quantities which are closely related to one another, are related also to the surface energy of dispersoids and to the energy of interaction between macromolecules and molecules of the liquid medium. On the basis of these two quantities we may make a direct study of the lyophilic properties of colloidal systems of all types. Owing to this interrelationship, Rebinder's proposal — that the coefficient q_1/q_0 (q_1 is the heat of wetting the dry object with water and q_0 is the heat of wetting with hydrocarbon) be taken as a measure of hydrophilic character — becomes applicable to all systems.

In our laboratory at the Institute of General and Inorganic Chemistry of the Academy of Sciences of the Ukrainian SSR (coworkers: S. F. Bykov, R. V. Voitsekhovsky, P. A. Demchenko, L. G. Demchenko, I. A. Dumansky, O. D. Kurilenko, Ya. F. Mezheny, R. V. Mikhalyuk, E. F. Nekryach, F. D. Ovcharenko, and V. I. Solnyshkin) detailed investigations have been made into the relationship between the heat of wetting and the amount of medium sorbed (generally water). Heats of wetting were determined on the dry colloids in an adiabatic calorimeter. Owing to the high magnitude of the heat change and to advantages gained by the use of an adiabatic calorimeter, the accuracy attained was fairly high. The amount of bound water can be determined in various ways [5-8], and the values obtained agree fairly well. For example, the amount of water bound by 100 g of dry starch, as determined cryoscopically, calorimetrically, by indicator methods, from the dielectric constant, from density determinations, and by other methods, is found to have the average value A = 33.4 g, the range of variation being 32-35 g.

2. In the final analysis, the heating of wetting is the result of interaction between molecules of the wetting liquid and molecules of the body being wetted. The nature of the forces linking molecules together varies and is dependent on the kinds of molecules that are interacting. Setting aside the forces of chemical interaction, we may mention that the interaction between molecules may result from orientation, induction, and dispersion effects. The

structures of the molecules determine which sort of interaction will predominate in any given case. Also, interaction between molecules may often result from hydrogen bonding. In such cases the hydrogen bond will be superimposed on the forms of interaction mentioned above. This fact is particularly important in the investigation of hydrophilic character.

Hydrogen bonding occurs in cellulose, starches, proteins, and other macromolecular compounds. This kind of bonding often predominates when water molecules interact with adsorbents and with molecules of macromolecular compounds in aqueous solutions.

3. Let us examine the case of the wetting of an insoluble adsorbent by water when the interaction between the molecules of the liquid and solid phases is due mainly to hydrogen bonding. The mechanism of wetting can be presented as follows. The molecules of liquid water $(H_2O)_n$ decompose into simple H_2O molecules with adsorption of heat ($-Q_d$ cal). Sorption of these on an unalterable sorbent then proceeds with evolution of heat ($+Q_w$ cal). When the process is carried out in a calorimeter we determine the quantity of heat

$$Q = Q_w - Q_d \qquad (1)$$

As a result of the process A grams of free liquid water becomes bound at the surface of the adsorbent. $Q/A = q$ is the heat of formation of 1 g of bound water. In the case of a highly polymeric adsorbent, the aggregates of which may dissociate into more simple ones on which sorption will occur, it is necessary also to take the heat of dissociation of the polymer aggregates, Q_k, into account, so that

$$Q = Q_w - Q_d - Q_k.$$

The magnitude of Q indicates that the heat of wetting is essentially the heat evolved in the passage of water from the free state to the bound state. This change can be regarded as a phase change, the new phase being characterized by its two-dimensional character – a film approximately one molecule in thickness. If in the wetting process A grams of water is bound by 100 g of dry substance and Q cal is evolved, then $100 \cdot Q/A$ is the heat evolved in the passage of 1 g of water into the bound condition. Investigations have shown that the heat of wetting various substances with water is constant when related to unit mass of bound liquid. For 1 g of bound water we may write $100 \cdot Q/A =$ = about 80 cal/g, or for 1 mole – about 1500 cal/g. The extent to which such constancy is observed [5] will be seen from Table 1.

TABLE 1

Substance	$100 \cdot Q/A$	Q	A	$\frac{1}{c} \Sigma \frac{\Delta q}{\Delta x}$
Potato starch	78	28.1	35.1	80
Sulfite cellulose	80	13.0	16.2	78.4
Agar	80	44.9	56	77.9
Gelatin (insol. fraction)	80	32.6	40.7	83.5
Silica gel	80	22.7	28.3	75.9
Soda soap (stearate)	80.5	4.5	5.6	80.0

TABLE 2

Kind of cellulose	A (per 100 g)	Q (cal/g)
Cotton	12.75	10.2
Sulfite	17.2	13.8
Nitric-acid	23.75	18.9
Sulfate	21.6	17.2

Rode [7], applying the data of various authors on the heats of wetting of dry soils and assuming that the lowest moisture regain A at which the differential heat of wetting is zero corresponds to bound water, calculated values of $100 \cdot Q/A$ and found that it had the same constant value of 80 cal/g. Moore's investigations (1953) confirmed the law that we had stated concerning the constancy of the amount of heat evolved when unit mass of bound water is absorbed, the cottons examined being various textile fibers [8]. In a study of the sorption coefficient of water, Andrianov [9] found that Q/A was very nearly constant.

The constant Q/A can be obtained graphically from the isotherm for integral heats of wetting Q as a function of the moisture regain of the adsorbent. Such isotherms were given by Rodewald [10] for starch. Many workers have determined isotherms of this sort in recent years. We have determined isotherms for starch, gelatin, silica gel, clays, etc., and some of the curves are shown in Fig. 1.

The integral curves can be used to construct curves for the differential heat of wetting as a function of the moisture regain of the adsorbent x (Fig. 2). The area bound by the curve and the axes of coordinates is equal to the integral heat of wetting of the dry adsorbent. Let us represent this area as a rectangle having one side equal to the

Fig. 1. Isotherms of integral heats of wetting: 1) potato starch; 2) gelatin; 3) agar; 4) sulfite cellulose.

Fig. 2. Isotherms of differential heats of wetting: 1) potato starch; 2) gelatin; 3) agar; 4) sulfite cellulose.

Fig. 3. Isotherms of the heats of interaction of cellulose with caustic soda solutions: 1) cotton; 2) sulfite cellulose; 3) nitric-acid cellulose; 4) sulfate cellulose.

Fig. 4. Isotherms of the heats of interaction of cellulose with caustic soda solutions (data from the literature): 1) natural cotton (Morrison et al.); 2) the same after mercerization; 3) sulfite cellulose washed with alcohol (Voitsekhovsky et al.); 4 and 5) the the same (different kinds); 6) cotton cellulose (Barratt and Lowig).

least moisture regain c at which the differential heat of wetting q= 0. I.e. the amount of bound water A, so that the other side will be equal to the amount of heat evolved when 1 g of water is bound. A whole series of integral-heat curves was treated in this way, and it will be seen (Fig. 2) that the heights of the r-rectangles (in the ordinate direction) are substantially the same, i.e. Q/A is a constant (about 80 cal).

The curves we have discussed correspond to the equation Q= f(x), which Rodewald and later investigators did not succeed in solving. Mchryach suggested that, on the basis of the wetting isotherms, it should be possible to prove the equation Q/A = constant [11].

In this graphical solution of the problem, there is no need for separate experiments to determine the amount of bound water. The extent to which the value of $100 \cdot Q/A$ approximates to $\frac{\lambda}{c} \Sigma \frac{\Delta q}{\Delta x}$ will be seen from Table 1.

If the phase A is considered to be a film wetting a surface of S sq·cm/g, then since $A = S \cdot \delta \cdot 1$:

$$q_s = \frac{80}{S} = 80 \cdot \delta,$$

this being the energy of formation of 1 sq. cm. As 80 and δ are constants (δ is the thickness of a unimolecular layer), q_s – the change in the total surface energy of the adsorbent – is also a constant. If we assume the value $\delta = 3$ A, we obtain $q_s = 101$ ergs/sq. cm. The value $\delta = 3$ A is taken from the paper of Harkins and Jura [12], in which they find that a film of water equivalent to five unimolecular layers has a thickness of 15 A. The resulting value of q_s is somewhat less than the total surface energy of water.

4. Let us analyze some examples of the application of our law.

a) Wetting of Starch. When the number of water molecules bound by sorption on starch is known, it is easy to calculate the number of water molecules n combined with one glucose residue of the starch:

$$n = \frac{0.334}{18} \cdot 162 = 3.$$

[0.334 g of water (mol. wt. 18) per gram of starch (mol. wt. of glucose residue 162)]. It will be seen that each glucose residue of the starch combines with three molecules of water.

Already in 1949-50 we turned our attention to the possibility of explaining the sorption of water by starch by the occurrence of hydrogen bonding. Now, after the work of Samets, we can speak quite confidently about this matter. Infrared-absorption investigations have shown that in dry starch hydrogen bonding can occur between hydroxyl groups. When water is present the water molecules unite in the first place with primary hydroxyls, and then with secondary hydroxyls. Hydrogen bonding can occur also with glucosidic oxygen.

Knowing the heating of wetting one gram of starch, $Q = 28.1$ cal/g, we may determine the heat for one basal mole of starch: $28.1 \times 162 = 4698.1$ cal; for one hydroxyl it is therefore 1566 cal. This quantity is not the heat of combination of H_2O and hydroxyl, but has a lower value, as indicated by Equation 1:

$$Q < Q_w$$

the difference being Q_d, the heat of formation of molecular aggregates from H_2O molecules.

It is interesting to note that, in passing from the free to the bound state, one mole of water gives up almost the same amount of heat (about 1500 cal) as it does when passing into the state of ice.

b) Wetting of Cellulose. Knowing that $100 \cdot Q = 80 \cdot A$, we may determine the amount of bound water in cellulose from the heates of wetting. Calculation of n gives a value of less then 3 (2 or 1). It is clear that the linking together of the molecular micelles in the strong fibers results in the screening of some of the hydroxyls, rendering them inaccessible to water molecules. When the cellulose is ground, n increases, even attaining the value 3. Mechanical disintegration may lead to ring rupture, exposure of hydroxyls, and increase in the number of possible interactions. The possibility of ring rupture is referred to by Stepikheev [13] and also by Pauca [14].

A knowledge of the amount of bound water and the heat of wetting enables us to estimate the optimum drying temperature, at which the hydrophilic character is not affected. Experiment shows that no change in hydrophilic character can be detected when drying is carried out in a vacuum at 55-60°.

Lauer [15] determined the heats of wetting Q of various kinds of cellulose and their densities in water and in carbon tetrachloride. From these densities we have calculated the amount of water bound by sorption (from Voinukhovsky's equation [16]), and, knowing Q (Lauer), we have calculated the value of $100 \cdot Q/A$, which was found to be about 80. Satisfactory confirmation of our law was thus obtained.

The view that the water molecules combine at the hydroxyls is confirmed by the experiments of Hokagawa [17], who studied the heats of wetting acetylated polysaccharides (starch, glycogen, and inulin) with water and showed that they were considerably lower than those of the unsubstituted materials.

As can be seen from Table 2, different kinds of technical cellulose have different heats of wetting and therefore differ in the amount of bound water (hydrophilic character).

Data on heats of wetting provide an approach to the explanation of the mechanism of mercerization with caustic soda solutions of various concentrations applied to various kinds of cellulose [18]. Experiments have shown that the heat of wetting with such solutions is a linear function of the alkali concentration C. The results of these experiments are shown in Figures 3 and 4. Heats of wetting of various kinds of cellulose are plotted as ordinates, and alkali concentration as abscissae. The result is a series of almost parallel lines, curved only in the neighborhood of the axis of ordinates. This family of straight lines satisfies the following equation:

$$Q = q_0 + \frac{dQ}{dC} \cdot C; \quad Q = q_0 + C \cdot \tan \alpha,$$

(Q is the heat evolved in the process, q_0 is a constant for each kind, and α is the slope of the curves); tan α varies from 1.10 to 1.25.

The quantity Q is made up of two quantities: q_0, the heat of wetting by water (see Table 2), and the heat of reaction with caustic soda. The heat of wetting by water is determined by the accessibility of the hydroxyls to the reagent, i.e. the degree of degradation of the fiber, which is not the same for different kinds of cellulose. On the basis of these experiments we may arrange the kinds of cellulose in the following series: cotton < sulfite < nitric-acid < sulfate.

c) As a further example, let us examine the hydrophilic character of Capron (6-nylon), which has the formula:

$$HOOC(CH_2)_5 \cdot NH[CO(CH_2)_5 \cdot NH]_n \cdot CO(CH_2)_5 \cdot NH_2^0$$

According to Mikhailov and Skuratov [19] the heat of wetting is 6.3 cal/g for the unoriented fiber and 6.8 cal/g for the oriented fiber.

From the equation M/n = 18 X 80/Q we obtain M/n = 229 and 212, respectively, for the fibers. The monomer has a molecular weight of M = 113. We thus see that for each pair of monomer units there is one hydrogen bond associated with a water molecule, the remaining hydrogen bonds being concerned in cross-linking the molecules among themselves. On the basis of infrared absorption spectrum measurements, Shigorin, Mikhailov, and Makaryeva [20] have shown that inter- and intra-molecular hydrogen bonding may occur in this system.

d) Soaps – Their Lyophilic Character [21]. The heats of wetting sodium stearate and sodium palmitate with water were determined, and with the aid of our formula the number of water molecules combining with one molecule of soap was calculated. It was found that one water molecule becomes attached, and the "hydrates" can be assigned the following formulas:

$$CH_3(CH_2)_{16}-COO \cdots\cdots H_2O$$
$$\quad\quad\quad

$$Q = 0.065 \cdot n.$$

In the wetting of stearate, therefore, the heat evolved should be 0.065 X 18 = 1.17 cal, which is close to the experimental value of 1.16 cal; for palmitate we have 0.065 X 14 = 0.91 cal, and experiment gives 0.94 cal.

This rule is applicable to saturated soaps and saturated hydrocarbons. In unsaturated soaps, the zig-zag form of the chain and the mobility of the molecule at the double bond results in a screening of the units of the chain by one another, and the amount of heat evolved is reduced. The amount of heat evolved is therefore given by:

$$Q = \frac{0.065}{2} \cdot n.$$

Oleate again contains 18 carbon atoms in the chain, but, as it contains a double bond, according to the formula it can give only

$$Q = 9 \text{ X } 0.065 = 0.58 \text{ cal.}$$

The experimental value is 0.54 cal, i.e. close to the calculated value. Ricinoleate, which has carbons in its chain, has Q = 0.47 cal. Here, in addition to the screening referred to above, the OH group screens the neighboring CH_2 group. The general formula for the wetting of such soaps with a hydrocarbon can therefore be written:

$$0.065\,(n/2-1) = 0.065 \text{ X } 7 = 0.45 \text{ cal,}$$

i.e. a value very close to that found experimentally (0.47 cal). On the basis of these experiments, with respect to oleophilic character the soaps can be placed in the series:

Stearate > oleate > ricinoleate

1.16 0.54 0.47 cal

e) On the basis of the heats of wetting of soaps by hydrocarbons we may give the energetic mechanism of detergency [22].

In order that fatty (oily) spots may be washed from a fabric, it is necessary that the energy of the attachment of the fat (hydrocarbon) to the fabric (e.g. cellulose) be less than the energy of the binding of the fat to the soap. Wetting of cellulose with octane yields 0.37 cal, with paraffin oil 0.35 cal, and with sunflower oil 0.46 cal. The heat of wetting soap with oil is

$$Q = n \cdot 0.065 \text{ cal.}$$

Hence, below sodium octanoate, for which Q = 8 X 0.065 = 0.52 cal, the sodium salts of fatty acids will have no detergency effect. Long experience confirms this view. It is probable that the same considerations explain the ability of soaps to increase the solubility of hydrocarbons in water [23]. In addition, the removal of solid particles is aided by their peptization by a surface-active substance, i.e. soap [24].

f) The system oil – soap – water is not a simple mechanical mixture, but is bound together by hydrogen bonding and by the energy of the dispersion effect in the given system. In order to establish the energy changes occurring in the formation of these systems, experiments based on the preceding conclusions were carried out.

Soap was wetted with water and then with paraffin oil, and in both cases thermal changes were observed. On the basis of the regularities already observed, we may draw up the following scheme of the formation of the ternary system oil – soap – water:

(oil) ↑ (soap) ↑ (water)

dispersion effect hydrogen bonding

The mechanical properties of these systems, which form the basis of a series of full-bodied lubricants, are associated with the chemistry of their formation. The anhydrous oleogels of oleate and ricinoleate, in combining with two and three molecules of water respectively, lower the limiting shear stress [25]. The further addition of water produces thickening.

g) With respect to heats of wetting, clays [26] vary considerably and give values of Q varying from 0.88 cal (Dubovo kaolin) to 21.0 cal (gumbrin). The heat of wetting is greatly affected by an absorbed cation, and an absorbed cation also greatly affects the amount of bound water (as determined by an independent method).

With respect to their effects on the heats of wetting of clays, absorbed cations can be arranged in the following order:

$$Ca^{++} > H^{+} > Na^{+} > K^{+},$$

whereas the heats of hydration of these cations are in the order:

H —255; Ca —174.5; Na —97; K —77.

The heat of wetting is found to be correlated with the mechanical properties of a clay dough, but since the heat of wetting is determined by the amount of water passing from the free to the bound state, this correlation refers to the amount of bound water A. The limiting shearing stress P_m was determined for different moisture contents of the dough. The measurements were made by means of a conical plastometer. From a series of such experiments Ovcharenko established the following relationship:

$$P_m = A \cdot e^{kc} \text{ or } \log P_m = \log A + kc \cdot \log e,$$

A, of course, can be replaced by Q, the necessary coefficient being introduced (k is an empirical constant).

Absorbed cations greatly affect the mechanical properties of the dough. The cations can be arranged in the same series as that given previously for heats of wetting.

5. In conclusion we will discuss the phenomena observed when water and alcohols penetrate into silica gel.

Many investigators have noted that the heats of wetting of silica gel by lower alcohols are greater than the heat of wetting by water, whereas for higher alcohols the heat of wetting is less than for water. The second statement is readily understandable: the large hydrocarbon radicals cannot penetrate into the narrow pores. The question of why alcohols, such as methanol and ethanol, having small hydrocarbon radicals give heats of wetting higher than that of water remains unresolved [27].

The difficulty with which water penetrates into the pores of silica gel [28] can be explained by the participation of water and silica gel in hydrogen bonding. Water molecules, being capable of two-sided hydrogen bonding:

$$H_2O \ldots\ldots H - O - H \ldots\ldots OH_2$$

may become attached simultaneously to the capillary wall and to other water molecules, and so build a structural formation of molecules within the capillary. Such a formation demands additional mechanical effort for its break-down. Alcohol molecules, which have only one hydrogen bond $CH_3OH \ldots OH_2$ and $C_2H_5OH \ldots OH_2$, can use it either for attaching themselves to the wall of the silica pore or for the formation of a dimer, but they cannot form aggregates attached to the capillary walls. In the wetting of starch, water molecules readily wedge their way into the starch aggregate and can then penetrate still further owing to the mobility (open structure) of the aggregate. Alcohol molecules cannot do this, since they contain hydrophobic hydrocarbon radicals that cannot take part in the "wedging" process. For this reason, the heat of wetting starch with water attains values of greater than 20 cal, whereas the heat of wetting with alcohol scarcely attains 1.6 cal.

We were still further confirmed in this view by the results of Dumansky and Khaflenko [29] on the rheological properties of moist glycerol and sucrose solutions, which were determined by means of a sensitive Shvedov apparatus constructed by these investigators. It was found that neither glycerol nor sucrose solutions are Newtonian liquids. These liquids are made up of hydrogen-bonded molecules, and so have structures that possess shearing moments. A solution of rosin in paraffin oil at the same viscosity is a true Newtonian liquid.

In conclusion we give a quantitative characterization of the concept of hydrophilic character.

The hydrophilic character of the surface or molecule of a high polymer must be determined by the number of active sites (radicals) that become attached to H_2O. We may therefore write:

$$\frac{aM}{18} = n; \; A = 100\,a; \; Q = 80 \cdot a,$$

in which a is the amount (g) of water bound by 1 g of adsorbent, 18 is the molecular weight of water, and n is the number of active centers at which water molecules are attached. In order to determine the value of n, it is essential to know M, the molecular weight of the colloidal substance. When the molecular weight is unknown, one of the following expressions can be considered to characterize the hydrophilic character:

$$M/n = 18/n \text{ or } n/M = n/18$$

The first expression indicates the fraction of the molecular weight corresponding to one active center. The second expression indicates the relative number of active centers in the molecule (micelle) of the colloid. The first quantity diminishes with increase in hydrophilic character, and the second quantity increases.

On the basis of these considerations we may write the following series arranged according to the value of 100 n/M:

Na stearate <	Na palmitate <	Capron <	cellulose <	
0.3	0.4	0.8	0.9-1.3	
silica gel <	starch <	gelatin <	agar	
1.6	1.9	2.3	2.5	

Thus, a detailed study of the wetting of various hydrophilic disperse systems and macromolecular colloids with water has made it possible to calculate that, in the binding of units mass of water by these adsorbents, the amount of heat evolved is always the same, namely 80 cal approximately, i.e. about 1500 cal per mole; this study has enabled us also to obtain a quantitative expression for hydrophilic character. Taking starch and cellulose as examples, we have shown how the rule of "constant heat of formation" can be applied to the solution of various problems relating to the hydrophilic character of systems. It was found to be possible to supplement existing views on the detergency of soap, regarded as the effect of a surface-active substance on the dissolution of hydrocarbons and the peptization of solid particles (soot, dust).

The results of our investigations enable us to regard the phenomenon of wetting as analogous to a chemical process.

SPECIFICITY OF THE CATALYTIC OXIDATION OF UNSATURATED HYDROCARBONS

L. Ya. Margolis and S. Z. Roginsky

The formation of oxygen-containing products by the direct oxidation of hydrocarbons by molecular oxygen tends to prevent far-reaching oxidation to Co, CO_2, and H_2O with complete breakdown of the carbon skeleton. In the literature [1] the view is firmly held that the main cause of the low specificity of the catalytic oxidation of hydrocarbons is the ready further oxidation and decomposition of the oxygen-containing compounds under the conditions of the synthesis. It is thus usual to represent the oxidation of olefins by the following stepwise scheme:

Twigg [2] proposed a scheme for the oxidation of ethylene in presence of silver in which aldehydes (formaldehyde and acetaldehyde) are intermediate products in the complete oxidation:

Pongratz [3], Sosin [4], and Dolgov [5] consider that the oxidation of aromatic compounds into phthalic anhydride and benzaldehyde proceeds in stages. Naphthalene, for example, is first converted into a naphthol, then into a naphthoquinone, then into phthalic anhydride, and finally into CO_2:

For this reason, in endeavoring to obtain the products of mild oxidation, many investigators have attached great importance to the selection of conditions under which oxygen-containing compounds will be removed rapidly from the reaction zone. There is a considerable basis for ascribing a higher reactivity to organic oxygen compounds than to saturated hydrocarbons, but this is not a general law, and in regard to olefins its applicability is not altogether obvious.

A comparative investigation carried out with two of the principle types of catalysts for mild oxidation — silver and vanadium pentoxide — showed that acetaldehyde and formaldehyde are oxidized considerably more rapidly than propene [6]. It follows that, for olefins also, the low specificity of the processes may be due, in certain cases, to unfavorable relationships between the rates of formation and transformation of intermediate stable oxygen-containing compounds (aldehydes, epoxides, acids), which hinder the accumulation of valuable products. However, this cannot be the only cause, and it cannot be general. Thus, in presence of silver, the oxidation of ethylene oxide — which is practically the only valuable product of the reaction — is slower than the oxidation of ethylene, but the selectivity of the process is nevertheless low owing to considerable formation of CO_2. Over the typical catalyst for the severe oxidation of hydrocarbons (platinum, magnesium and copper chromites, etc.) at 300-400°, aldehydes are oxidized mainly to acids and only partially to CO_2 [7]. Under these conditions both unsaturated and saturated hydrocarbons are oxidized to water and carbon dioxide, and only traces of aldehydes and acids can be detected in the reaction products. These observations give us grounds for a cautious and critical attitude to the accepted stepwise schemes — not proved by direct experiment — for the oxidation of hydrocarbons. The method of labeled atoms combined with an investigation of the kinetics of the process should enable us to establish the genetic relationships between the individual reaction products. In particular, by the introduction of radioactive carbon C^{14} into the reactants — in some cases into the molecule of the original organic compound, and in other cases into the proposed intermediate product of far-reaching oxidation — and by the determination of the distribution of radioactivity among the reaction products, it should be possible to establish the way in which the products arise and the rates of the component reactions of the complex process.

In the present investigation we attempted to determine the genetic relationship between the various stable oxygen-containing compounds formed in the catalytic oxidation of hydrocarbons*. In some of the experiments the oxidation was carried out under static conditions at a pressure of 0.5-0.8 mm, and in others it was carried out under dynamic conditions at atmospheric pressure. In the analysis of the reaction products, CO_2, CO, O_2, and hydrocarbons were determined by volumetric analysis, aldehydes by the hydroxylamine and polarographic methods, and ethylene oxide by absorption in a mixture of HCl + NaCl. For the experiments with labeled molecules, active ethylene [8] and acetaldehyde [9] were prepared by methods developed previously. The radioactivities of the original compounds and isolated reaction products were determined in the form of barium carbonate with end-on counters having mica windows. Typical catalysts for mild oxidation were used: silver and oxides of metals of Groups V and VI of the periodic system.

EXPERIMENTAL

1. Oxidation of Ethylene in presence of Silver. Fig. 1 and Table 1 present data on the distribution of radioactivity between CO_2 and C_2H_4O in the products of the reaction between C^{14}-labeled ethylene, ethylene oxide, and oxygen in presence of silver at 220°. The specific activity of CO_2 is close to that of ethylene and is considerably greater than that of ethylene oxide. From the specific radioactivities it is easy to calculate the proportion of the carbon dioxide that is formed directly from ethylene without passing through ethylene oxide: at 220° it is 80%, and the proportion formed by the complete oxidation of ethylene oxide is about 20%. According to the most generally accepted scheme, which is due to Twigg, carbon dioxide is formed via aldehydes without passing through ethylene oxide, via formaldehyde, and by the complete oxidation of ethylene oxide formed via acetaldehyde (see Scheme 1). By oxidation of a mixture of C^{14}-labeled ethylene with, in some cases, acetaldehyde and, in other cases, formaldehyde and determination of the concentrations and specific activities of the various reaction products, it is possible to establish the rates of the component reactions of the individual compounds and their mixtures. In Fig. 2 we give reaction-rate diagrams (arbitrary units) for the formation of ethylene oxide and carbon dioxide in presence

---

* By stable products we mean substances that can be isolated and determined analytically by the usual chemical methods, as distinct from radicals and other unstable forms, which can be detected only by spectrum, magnetic, and other such methods, or by the analysis of indirect kinetic data.

Fig. 1. Variation of the specific radioactivities of ethylene oxide (1) and carbon dioxide (2) during reaction between C^{14}-labeled ethylene, ethylene oxide and oxygen in presence of silver at 220°.

of silver in the oxidation by molecular oxygen of mixtures of ethylene and ethylene oxide, ethylene and acetaldehyde, and ethylene and formaldehyde. In presence of formaldehyde and acetaldehyde the rate of formation of ethylene oxide increases somewhat and the rate of formation of carbon dioxide diminishes. Aldehydes, therefore, do not intensify the formation of carbon dioxide and therefore cannot be the principal intermediaries in the formation of CO_2, either from ethylene without passing through ethylene oxide, or from ethylene oxide itself.

2. Oxidation of Ethylene and Propene in presence of Vanadium Oxides. In the oxidation of ethylene and propene over V_2O_5, the reaction products were shown to contain formaldehyde, acetaldehyde, formic acid, and acetic acid, and also appreciable amounts of carbon monoxide and dioxide. We were

unable to detect even traces of ethylene oxide and propylene oxide among the reaction products. In order to determine the genetic relationships between the various stable oxygen-containing products, rates of oxidation by molecular oxygen were measured for C^{14}-labeled mixtures of 1) ethylene and ethylene oxide and 2) ethylene and acetaldehyde. The distribution of activity among the various reaction products was determined (see Table 2). It was found (Fig. 3) that the rate of formation of carbon dioxide is not affected by the presence of acetaldehyde in the mixture and is reduced by the presence of ethylene oxide. Consequently: 1) neither acetaldehyde nor ethylene oxide can be a principal intermediate product in the

Fig. 3. Reaction-rate diagrams for the formation of aldehydes, carbon monoxide and carbon dioxide in the oxidation of pure ethylene and its mixtures with ethylene oxide and acetaldehyde in presence of V_2O_5 at 400°.

TABLE 2

Oxidation Reactions in a Mixture of Ethylene, Acetaldehyde, and Oxygen over V_2O_5 at 400°

Composition of mixture (% by volume)			Specific radioactivity of original substances (impulses/min · mg)	Specific radioactivity (impulses/min · mg) of	
C_2H_4	CH_3CHO	O_2		CO_2	CO
30	25	45	$CC^{14}H_4 = 740$	556	515
40	20	40	$CC^{14}H_4 = 250$	85	68
28	25	47	$CC^{14}H_4 = 840$	209	208

formation of carbon dioxide, and 2) although the rate of formation of carbon monoxide is increased in presence of ethylene oxide and acetaldehyde, radiometry shows that the rate of formation of CO from aldehyde is increased simultaneously, so that there is reason to suppose that both for CO_2 and for CO neither an aldehyde nor ethylene oxide can be the main intermediate product in the reactions.

Under the experimental conditions, there was practically no oxidation of carbon monoxide to carbon dioxide. It was therefore possible to make separate examinations of the origins of these substances. The effect of aldehyde in simultaneously encouraging the formation of CO and discouraging the formation of CO_2 indicates that CO and CO_2 are formed from hydrocarbons by independent parallel routes via unidentified intermediate products.

DISCUSSION OF RESULTS

There is an essential difference between the catalytic actions of silver and vanadium oxides: over silver the addition of oxygen at the double bond with formation of ethylene oxide predominates under certain conditions whereas over vanadium oxides under a wide range of external conditions no olefin oxides can be detected among the reaction products. On the other hand, the formation of aldehydes and acids over V_2O_5 and other oxides (WO_3, MoO_3, etc.) is considerably greater than over silver. In spite of these differences in the composition of the products for oxide catalysts and for silver, the isotope data are very similar in certain respects. For example the further oxidation or decomposition of ethylene oxide over an oxide catalyst or of aldehydes over silver is not the main cause for the absence of these substances among the reaction products. In the oxidation of ethylene over silver and of ethylene and propene over oxides, the successive formation of several stable oxygen compounds either did not occur at all or played a minor part in comparison with their formation in parallel reactions. In the oxidation of hydrocarbons over these catalysts, the formation of carbon dioxide and carbon monoxide also occurs mainly without intermediate formation of

aldehydes and ethylene oxide. Data from the literature and the results of our measurements suggest the following as a likely scheme for the catalytic oxidation of hydrocarbons:

Y being the hydrocarbon, K the catalyst, and R_1 to R_5 labile intermediate products, probably of the peroxide radical type. This conclusion is of great importance for the determination of the direction of further investigations. In order to obtain better results it is first of all necessary to search for catalysts that will direct the reaction into the course desired and to suppress parallel reactions by regulating the chemical composition of the catalyst and varying the conditions of the process. Only then should steps be taken to remove the products of mild oxidation from the reaction zone so that they are isolated without decomposition.

Each of these parallel courses of the oxidation reaction is a complex stepwise process. The kinetic and isotopic data that we have presented lead only to a negative conclusion – that the reactions do not pass through intermediate stable compounds. Positive indications of the nature of the intermediate stages and products are given by the investigation of isotopic exchange, the analysis of the kinetic equations, and some other data. It is likely that the first step is the formation of the singly charged molecular ion O_2^-. The intermediate complex of the determining stage contains O_2^- and, probably, a firmly adsorbed hydrocarbon molecule. Among other intermediate active forms of oxygen are O^- ions and possible also O_3^- ions. Intermediate forms occurring in catalytic oxidation differ substantially from analogous forms occurring in homogeneous oxidation*.

In our investigation we have obtained similar pictures for two hydrocarbons and three oxidizable oxygen compounds. Silver is a typical metal catalyst for mild oxidations, but according to the literature copper and its alloys are in many cases similar to silver. Our results and data in the literature indicate that V_2O_5 is a member of a group of oxide catalysts (WO_3, MoO_3, UO_3, etc.), all of which give similar results. It may be considered, therefore, that the relationships we have found are of fairly wide application, particular to the oxidation processes of aromatic hydrocarbons and alcohols. This view should be verified by the method of radioactive indicators, since all other methods give ambiguous results.

SUMMARY

1. It was shown that, in the oxidation of ethylene over silver, aldehydes cannot be the main intermediate products in the formation of carbon dioxide.

2. It was shown that in presence of V_2O_5 carbon monoxide and dioxide are formed by independent parallel routes, which do not proceed via aldehydes.

3. A probable scheme for the catalytic oxidation of hydrocarbons is given.

STRUCTURE OF SODIUM BOROSILICATE GLASSES IN ITS RELATION TO THE PHENOMENON OF OPALESCENCE

COMMUNICATION 4. DEPENDENCE OF THE STRUCTURE OF SODIUM BOROSILICATE GLASSES ON THE DURATION OF HEATING AT CONSTANT TEMPERATURE

E. A. Porai-Koshits, D. I. Levin, and N. S. Andreev

In previous communications by the first two authors of the present paper and Zhdanov, experimental results were given of a study of the scattering of visible light by sodium borosilicate glasses capable of opalescence and susceptible to leaching [1], the experimental results were presented also on an X-ray and electron-microscope investigation of the structure of the porous products obtained by leaching these glasses [2], and the authors gave their views on the structure of the unleached glasses ("submicroheterogeneous structure") and the causes of their opalescence [3]. According to these views, the increased intensity of light-scattering observed when the temperature of the glasses is raised in the opalescence zone (about 550-700°) is to be explained by the growth of the regions of chemical heterogeneity, which are present even in completely clear glasses, but are then of comparatively small dimensions. The experimental basis for these views was obtained in a comparative study of the structures of porous products obtained by the leaching of opalescent and clear glasses, which were prepared by maintaining samples of glass at temperatures in the opalescence zone and at higher temperatures, respectively.

On the basis of our views it would be expected that the relation between the degree of opalescence of a glass and the structure of the porous product obtained by leaching the glass would be observed also for glasses for which the scattering intensity varies with the duration of heating at constant temperature (in the opalescence zone). The experimental verification of this supposition formed the object of the present investigation.

EXPERIMENTAL

Experimental Procedure

A comparative study was made of the scattering intensities of sodium borosilicate glasses heated at constant temperature (600° or 650°) for various times and of the submicroscopic structures of the porous products obtained from these glasses by leaching; the structures were studied by the method of small-angle scattering of X-rays. The sodium borosilicate glass selected for investigation contained 70 moles % SiO_2, 23 moles % B_2O_3, and 7 moles % Na_2O, this being the most typical of the glasses capable of opalescing and being leached. In order to determine scattering power, samples of glass were prepared in the form of rectangular blocks 9 × 12 × 40 mm, polished on all faces. These samples, and also pieces of glass for X-ray examination, were placed in a muffle furnace and kept there for various times at one of the two fixed temperatures (Table 1).

Constancy of temperature was maintained by means of a thermoregulator. After the period of heating the samples of glass were quenched in the air. The samples obtained at the two different temperatures differed greatly in appearance. The samples quenched from 600° remained clear, only the sample maintained at this temperature for eight hours showing scattering that was scarcely perceptible by the eye. All of the samples quenched from 650° were strongly opalescent, the degree of opalescence increasing considerably with increase in the duration of heating.

This behavior made it necessary to measure the scattering powers of the glasses quenched from the different temperatures by two different methods. The scattering of glasses treated at 600° was measured by a method similar to that described previously [1]*. The scattering coefficients of glasses quenched from 650° could not be measured by the same method because of the occurrence of repeated scattering [1, 4]. Hence, the scattering powers of these glasses were characterized by their transmission coefficients* (i.e. the ratio of the amount of transmitted light to

* The authors thank A. I. Kalyadin for measuring, at their request, the scattering coefficients of glasses quenched from 650°.

the amount of incident light). The correctness of this procedure follows from Gurevich's results [5], which show by direct measurement that in sodium borosilicate glasses the absorption of visible light is negligible in comparison with its scattering.

Measurements of transmission coefficients were carried out on an SF-4 photoelectric spectrophotometer. A filament lamp was used as light source. In order to select the most suitable wavelength for comparison of scattering by the glasses (such that the light would be appreciably weakened in all of the samples investigated), transmission-wavelength curves were determined in all of the samples quenched from 650°. These curves are shown in Fig. 1, from which it will be seen that it would be most satisfactory to compare transmission coefficients at a wavelength of 650 mμ.

Glasses for X-ray investigation were ground to a powder of grain size 0.12-0.16 mm and treated with 3 N HCl for 24 hours at a constant temperature of 50°. The leached samples were washed free from residual acid by means of running distilled water, dried, and treated further with 0.5 N KOH for two hours at room temperature. Further rinsing and drying yielded grains of porous glass containing clean channels free from highly dispersed silicic acid. This treatment enabled us to obtain samples of porous glass that gave good small-angle scattering of X-rays. The general features of the structures of the siliceous skeletons of the original glass and the porous product of leaching obtained in this way were determined in previous investigations [2, 3]. The same papers describe the views of the authors concerning the nature of the processes occurring when sodium borosilicate glasses are treated with acids and alkalis.

Small-angle X-ray photographs were obtained in vacuum cameras with CuK_{α} radiation ($\lambda = 1.5418$ Å) rendered monochromatic by reflection from calcite; the distance between sample and plate was 200 mm. Microphotometric measurements were made on the X-ray photographs with the aid of an MF-4 autorecording microphotometer.

Experimental Results

Analysis of our curves for the dependence of the transmission coefficient τ on wavelength (Fig. 1) confirms the result first obtained by Levin and later studied in detail by Gurevich [5]: in sodium borosilicate glasses scattering intensity is proportional to λ^{-n}, n being greater than 4 and, according to Gurevich's results, having a value of about 8. This value is closely in accord with our results, with the exception of results for a narrow spectrum range in the shorter waves, in which n is in the region of 6. This range, however, is narrow, and in the remaining part of the visible spectrum our measurements also give a value of 8 for the index.

In Table 2, Column 6 we give the results of measurements of the intensity of visible scattering by glasses quenched from 600° relative to that of unheated glass No. 1, the scattering intensity of which was 16 times the molecular scattering of ether ($I/I_{ether} = 16$). Fig. 2 shows the dependence of $1-\tau$, which characterizes the

scattering, on the duration of heating at 650°. These results confirm the relation found for the change of scattering in the opalescence zone which we obtained previously [4]. It will be seen from Fig. 2 that, as heating is continued at constant temperature (in the opalescence zone), the scattering intensity increases. The rate of the increase in intensity is the greater, the higher the temperature of the heat treatment.

TABLE 2

6	650	1		250	

* Scattering intensity of this sample, as compared with the molecular scattering of ether $I/I_{ether} = 16$.

In the preceding communication [3] we explained the growth in the scattering intensity with rise in temperature in the opalescence zone by growth in the regions of heterogeneity — regions of components dispersed through the silica skeleton, which contain boron oxide and sodium silicate. A similar explanation can be given for the growth in the intensity of scattering with increase in the duration of heating. Leaching of the glasses should then give porous glasses of increasing pore size [2, 3], and pore-size measurements should give information concerning the dimensions of the regions of heterogeneity in the original unleached glasses. We carried out such measurements by the method of small angle scattering of X-rays.

Fig. 3 gives microphotometric curves for samples of porous glasses prepared from glasses quenched from 600° (Samples 2-5, Table 1). It will be seen from Fig. 3 that the interference maximum, which can be clearly observed on the curve for Sample 2, moves to smaller scattering angles as heating is prolonged until it disappears behind the trap for the primary beam.

The curves having maxima permitted the determination of the radii of the most frequently occurring pores from the position of the interference maximum ($R = 0.32 \frac{\lambda}{\varphi_m}$) and of the radii of the smallest pores from the slope of the tangent drawn to the curve (log I, φ^2) in the region of the greatest scattering angles; to the remaining curves only the method of tangents was applied [2]. It must be noted that the collimation correction, which is applied to the position of the interference maximum by taking into consideration the final cross-sectional area of the primary beam, was not made, and all pore dimensions determined from the position of the maximum must be considered to be too high by 10-20%. Table 2 gives the results of calculations by both methods: R_m is the radius calculated from the angular position φ_m of the interference maximum, and R_1 is the smallest radius determined from the "tail" of the curve. The results obtained will be discussed below.

The X-rays photographs of porous glasses prepared from glass quenched from 650° were all taken with an exposure of 10 minutes. Both the microphotometric curves (Fig. 4) and the intensity curves (Fig. 5) show that the total intensity of small-angle scattering diminishes with increase in the duration of heating. The duration of heating is indicated by figures on the curves; the other samples gave intermediate curves.

In order to compare the forms of the intensity curves at suitably selected exposures, intensity curves were obtained having identical values for the maximum intensity (i.e. at the least possible scattering angles). Within the limits of error for the determination of very low intensities, the curves for all samples quenched from 650° coincided. The pore radius calculated by the method of tangents is given in the last line of Column 5, Table 2.

Discussion of Experimental Results

The microphotometric curves in Fig. 3 show that with increase in the duration of heating of glass quenched from 600° the interference maximum moves to smaller angles until, finally, the maximum is covered by the trap for the primary beam of X-rays. From this fact we may draw the purely qualitative conclusion that, as heating of the original glass is prolonged, the radius of the most frequently occurring pores of the leached samples increases. The calculated radii of the pores (Table 2) confirm this conclusion. As at the same time there is an increase in

the scattering intensity of the original glasses (Column 6, Table 2), we readily reach the conclusion drawn in previous communications, i.e. that the cause of the increased scattering intensity is the growth, with increased duration of heating at 600°, of the regions of chemical heterogeneity that are present in the glasses.

The rise in the scattering power of the glasses with increase in the duration of heating is still more characteristic of samples quenched from 650°, as will be clear from an examination of Fig. 2. Judging from the preceding results, for these samples also, we should expect a considerable increase in the dimensions of the regions of heterogeneity. However, as indicated above, judging from the X-ray photographs for the corresponding porous glasses, the dimensions of the regions of heterogeneity of all the samples are identical within the experimental error.

This contradiction is only apparent, and it is readily explained when we take into account a feature of behavior that can be derived from Figures 4 and 5: these show that the scattering intensity for X-rays (in the region of scattering angles bounded under the conditions of the experiments by the least possible angle $\varphi_{min} \approx 10'$) falls systematically as the duration of heating of the original glasses is increased. This behavior is quite the reverse of that observed for porous glasses prepared from original glasses quenched from 600°: for these the scattering intensity was the greater, the longer the original glass was maintained at this temperature. The most sensible explanation is therefore that the reduction in intensity observed for Samples 6-12 (Fig. 5) is due to reduction in the number of regions of heterogeneity (in this case pores) having relatively small dimensions (radius less than about 500 A), for the scattering intensity at small angles is proportional to the number of scattering regions of heterogeneity. During the heating there is an increase in the size and number of the larger regions of heterogeneity (radius greater than 500 A) at the expense of the smaller regions, and after the leaching the sample contains mainly large pores, the scattering by which — owing to the inadequate resolving power of the apparatus at our disposal — falls in the region covered by the trap for the primary beam.

Hence, the observed reduction in the intensity of X-ray scattering (Fig. 4) does not contradict the views previously advanced by the authors [2, 3], according to which increase in the intensity of light scattering is to be explained by the growth of the regions of heterogeneity, which, in their turn, determine the formation of more coarsely porous glasses. The immediate problem in the investigation of sodium borosilicate glasses capable of showing opalescence is the improvement of the procedure for measuring X-ray scattering at small angles so that the upper limit of the size of regions of heterogeneity — which apparently lies close to the wavelength of visible light — may be found. The solution of this problem is of fundamental interest not only for a more accurate determination of the structure of sodium borosilicate glasses, but also for the theory of scattering by turbid media.

SUMMARY

1. The intensity of the scattering of light by sodium borosilicate glasses increases with increase in the duration of heating at constant temperature in the opalescence zone.

2. When the glasses are heated at constant temperature in the opalescence zone, the pore size of the porous glasses obtained by the leaching of the heated glasses increases.

3. The increase in the intensity of light scattering with increase in duration of heating at constant temperature in the opalescence zone is to be explained by growth of the regions of chemical heterogeneity present in sodium borosilicate glasses, a view that is confirmed by an examination of the submicroscopic structure.

SYSTEMS CONTAINING HYDROGEN PEROXIDE AT HIGH CONCENTRATION

COMMUNICATION 11. CHARACTERIZATION OF THE SOLID PHASES OF THE SYSTEM LiOH – H_2O_2–H_2O BY THERMAL ANALYSIS

S. Z. Makarov and T. A. Dobrynina

Compounds of lithium peroxide with hydrogen peroxide and water have received little study. The first compound of this type $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ was prepared by de Forcrand [1] by the action of hydrogen peroxide on aqueous-alcoholic solutions of lithium hydroxide. According to de Forcrand's results, the decomposition of $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ in the cold in a vacuum over phosphoric oxide for 36 days occurs with simultaneous loss of water and hydrogen peroxide and formation of anhydrous lithium peroxide. Pierron [2] was unable to confirm de Forcrand's results. In the dehydration of the compound $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ in a vacuum over phosphoric oxide, Pierron obtained a preparation of composition $Li_2O_2 \cdot 0.18H_2O_2 \cdot 3.09H_2O$.

Agunzi [3] showed that, when $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ is heated for six hours in a vacuum over phosphoric oxide at the temperature of boiling ether, it loses its water completely and also 0.4 of a molecular proportion of hydrogen peroxide; he concluded that in hydrates of perhydrates water is bound less firmly than hydrogen peroxide. Agunzi explained the results obtained by de Forcrand [1] by the prolonged drying of the $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$. Cohen [4] treated a suspension of lithium ethoxide in absolute ethanol with 30% hydrogen peroxide and obtained a compound which he characterized as the monohydrate of lithium hydroperoxide $LiOOH \cdot H_2O$. An X-ray structure analysis carried out by Cohen on his preparation of $LiOOH \cdot H_2O$ and on preparations obtained by de Forcrand's [1] and Pierron's [2] methods showed that they were all the same substance. Cohen, therefore, denied the existence not only of $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$, but also of lithium peroxide compounds of the perhydrate type in general. According to Cohen, lithium hydroperoxide is stable only when in equilibrium with the mother solution, but is unstable after being dried; it can be preserved for a short time in an open vessel if cooling is applied. By the vacuum drying of lithium hydroperoxide monohydrate over phosphoric oxide at 20 mmfor 18 days, Cohen obtained a preparation containing 99% of Li_2O_2.

In spite of Cohen's observations, Feher [5] noted that the phase $Li_2O_2 \cdot H_2O_2$ or LiOOH, i.e. anhydrous lithium hydroperoxide, gives a clearly defined Debye diagram. Cohen [4] assigns the compound $LiOOH \cdot H_2O$ to the rhombic syngony and gives the following values for the parameters of its crystal lattice: a = 7.92 A; b = 9.52 A; c = 3.20 A. According to Cohen the density of $LiOOH \cdot H_2O$ is $d_{calc} = 1.60$, $d^{25}_{expt} = 1.69$. The refractive indices for the $LiOOH \cdot H_2O$ crystal, determined by the immersion method, are $\alpha = 1.458$ and $\gamma = 1.526$.

A study that we made [6] of the solubility isotherms of the system $LiOH–H_2O_2–H_2O$ showed the existence of lithium peroxide perhydrates of composition: $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$, $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ ($LiOOH \cdot H_2O$ according to Cohen), and $Li_2O_2 \cdot 2H_2O_2$. The compounds $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$, $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$, and $Li_2O_2 \cdot 2H_2O_2$ have been isolated and studied by the method of thermal analysis.

The heating curves for the preparations of $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ and $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ coincided, although solubility isotherms in the system $LiOH–H_2O_2–H_2O$ clearly indicate the existence of two individual hydrates of lithium peroxide monoperhydrate $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ and $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ [6]. It may be supposed that the phase $Li_2O_2 \cdot H_2O_2 \cdot 3H_2O$ has a high vapor pressure and exists only in equilibrium with the mother solution. The individuality of the compounds $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ and $Li_2O_2 \cdot 2H_2O_2$ was confirmed by X-ray qualitative phase analysis, which was carried out by G. A. Goldee.

EXPERIMENTAL

The thermal decomposition of lithium peroxide perhydrates was investigated by the method of differential heating curves with a photorecording Kurnakov pyrometer. The samples under investigation were placed in pyrix test tubes or Stepanov vessels. The exit tube of the Stepanov vessel was connected through an absorption vessel

containing sulfuric acid to a measuring buret, which permitted the volume of gas evolved in the thermal decomposition of lithium peroxide perhydrates to be measured quantitatively. The samples were heated at a rate of 4-6° per minute. In the determination of the heating curves with the pyrometer, samples weighing 0.2-0.5 g were taken of the limiting peroxide perhydrates.

In the study of the thermal decomposition of lithium peroxide perhydrates in Stepanov vessels, the curves obtained for gas evolution as a function of time were superimposed on the corresponding heating curves, so that it was possible to determine which thermal effect corresponded to the evolution of oxygen.

Thermal Analysis of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$. Fig. 1 shows the heating curve for $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ determined in an open Pyrex test tube. Under these conditions the thermal decomposition of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ is characterized by two well defined endothermic effects, which begin at 85° and 310°, and by a small one at 65°. On the differential heating curve there is a small inflection at 95°. In order to interpret the thermal effects obtained, samples of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ were heated in a furnace to the required temperature and then analyzed for content of lithium and active oxygen. The lithium content was determined from the alkalinity (titration with 0.1 N H_2SO_4), and active oxygen by titration with 0.1 N $KMnO_4$ in acid solution. The results for the thermal decomposition of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ in an open vessel are given in Table 1.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

As will be seen from Table 1, in the temperature range 100–170° the preparation $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ loses all of its hydrogen peroxide and almost all of its water, and is converted into 85% lithium peroxide. Up to 310° lithium peroxide is stable. Heating to 320° results in the partial loss of its active oxygen. Thus, the endothermic effect on the heating curve of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ in the range 85–100° corresponds to the separation of hydrogen peroxide and water. The inflection on the differential curve at 95° corresponds to the superposition of the exothermic effect of the decomposition of hydrogen peroxide on the endothermic effect of dehydration. The endothermic effect at 65° corresponds to the removal of mother liquor from the $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ preparation. It was shown previously that Li_2O_2 decomposes at 318–320° [7] and the second endothermic effect on the heating curve (310°) corresponds to the decomposition of lithium peroxide formed from $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$.

In order to characterize the process of oxygen evolution from $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$, a heating curve was determined in a hermetically sealed Stepanov vessel. The resulting heating curves and the curve for oxygen evolution are shown in Fig. 2. Table 2 gives the data from which the gas-evolution curve was constructed.

As the oxygen-evolution curve in Fig. 2 shows, the endothermic effect beginning at 85° corresponds to intense evolution of oxygen from hydrogen peroxide, which comes to an end at 110°. Table 3 gives data for the interpretation of the heating curve of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$, determined in a closed vessel.

When the preparation $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ was heated in a Stepanov vessel to 110°, it lost 0.60 of a molecular proportion of H_2O_2. Heating to 150° led to complete loss of hydrogen peroxide, the loss of about one molecular proportion of water, and the partial decomposition of the lithium peroxide formed from $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$. When the temperature of heating is 175°, the content of lithium peroxide in the preparation reaches a maximum, after which the decomposition of lithium peroxide begins, this being brought about by water vapor present in the vessel (see the curve for the evolution of oxygen, Fig. 2, beginning from 175°).

The preparation obtained by heating $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ at 320° contained 24.37% of Li_2O_2, 74.69% of LiOH, and 0.94% of H_2O. Gas evolution from 318° onward (Fig. 2) and the endothermic effect that begins at this temperature corresponds to the decomposition of the lithium peroxide that remains in the preparation in admixture with lithium oxide hydrate. The next endothermic effect, which begins at 420°, corresponds to the fusion of the lithium oxide hydrate with the glass of the vessel.

The heating curve determined for $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ in a closed Stepanov vessel differs somewhat from the heating curve determined in an open Pyrex test tube. This is to be explained by the decomposition of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ when heated in a closed vessel and the action of water vapor on the lithium peroxide formed.

Thermal Analysis of $Li_2O_2 \cdot 2H_2O_2$. The $Li_2O_2 \cdot 2H_2O_2$ preparation, which contained 35.04% of active oxygen and 6.78% of lithium, was given a preliminary wash with ether to remove the mother liquor that it contained. Fig. 3 gives the heating curve for $Li_2O_2 \cdot 2H_2O$, determined in a Pyrex test tube. After a small endothermic effect at 40°, which was associated with the removal of residual ether, a large exothermic effect quickly followed. The temperature of the sample rose to 95-100° owing to the evolution of heat in the decomposition of hydrogen peroxide and the conversion of $Li_2O_2 \cdot 2H_2O_2$ into the hydrate of lithium peroxide monoperhydrate. Further heating of the preparation gave a differential curve similar to the heating curve of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$. It must be mentioned that $Li_2O_2 \cdot 2H_2O_2$ preparations are unstable under ordinary conditions, and they cannot be kept at room temperature for more than 15-20 minutes, in the course of which decomposition gradually occurs and is finally accompanied by a sharp rise in temperature, the preparation then decomposing completely to a solution of lithium hydroxide.

The oxygen-evolution curve corresponding to the heating curve of $Li_2O_2 \cdot 2H_2O_2$ determined in a Stepanov vessel (Fig. 4 and Table 4) showed that the exothermic effect beginning immediately after the removal of the washing liquid from the preparation (50-60°) corresponds to intense gas evolution, which continues to 110°. When the heating curve for $Li_2O_2 \cdot 2H_2O_2$ was determined in a Stepanov vessel (Fig. 4), after decomposition of hydrogen peroxide and dehydration, these followed, beginning at 190°, the decomposition of lithium peroxide under the influence of water vapor.

TABLE 4

Data on the Evolution of Oxygen in the Thermal Decomposition of $Li_2O_2 \cdot 2H_2O_2$

Duration of experiment (minutes)	Amount of oxygen (cc)	Duration of experiment (minutes)	Amount of oxygen (cc)	Duration of experiment (minutes)	Amount of oxygen (cc)	Duration of experiment (minutes)	Amount of oxygen (cc)

13	7.31	27	55.16	45	62.71		

SUMMARY

1. Study of the thermal decomposition of $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ and $LiO_2 \cdot 2H_2O_2$ showed that, when these compounds are heated to 150-170°, they are converted into Li_2O_2 with simultaneous loss of H_2O_2 and H_2O.

2. The simultaneous loss of H_2O_2 and H_2O by the preparation $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$ and its conversion by heat into Li_2O_2 give grounds for assigning a perhydrate structure to this compound, i.e. $Li_2O_2 \cdot H_2O_2 \cdot 2H_2O$, and not the hydroperoxide $LiOOH \cdot H_2O$.

3. The compound $Li_2O_2 \cdot 2H_2O_2$ was isolated for the first time, and its individuality was confirmed by the thermal method.

PHYSICOCHEMICAL STUDY OF THE SYSTEM SODIUM SUPEROXIDE – SODIUM OXIDE

T. V. Rode and G. A. Golder

Sodium Peroxide (Na_2O_2) was first prepared in 1810 [1, 2] by heating sodium in an atmosphere of oxygen; its composition was determined in 1839 [3], and later confirmed in 1862 [4]. According to some data [5-7] sodium peroxide melts at about 460° without decomposition, which sets in only in the liquid state when heating is continued further; but according to other data [8, 9] it decomposes in the solid state. Sodium peroxide greedily absorbs moisture and carbon dioxide from the air, and at high temperatures it reacts with most metals [5, 6] and with various oxides [10-12] and silicates [13].

Sodium Superoxide (NaO_2) was first synthesized in 1936 by Kazarnovsky [14]. From 1948 onward Kleinberg and coworkers published a series of papers on the synthesis, analysis, and magnetic behavior of NaO_2 [15-17], and then on the reactions of NaO_2 and KO_2 with the nitrates of various metals in liquid ammonia [18, 19].

Kazarnovsky [14], Templeton and Bauben [20], and Zhdanov and Zvonkova [21] ascribe a cubic structure of the NaCl type of sodium superoxide.

Later, Carter and Templeton [22] found, by X-ray analysis of a monocrystal, that at room temperature NaO_2 has a disordered structure of the pyrite type, the parameter of which was found by Zhdanov and Zvonkova [21] to be 5.44 A.

In 1953 one of us [23] showed by the method of differential thermal analysis that sodium superperoxide has two low-temperature polymorphous modifications with transitions at −80° and −43°. At these temperatures the differential cooling curves showed two reversible exothermic effects that could be explained by these transitions. We detected similar effects for KO_2. In the same year three papers [22, 24, 25] appeared which confirmed our results on the existence of two low-temperature modifications of NaO_2 by other methods. Thus, in the article by Zhdanov [24], which reviews X-ray investigations carried out in his laboratory, it is stated that two phase transitions of NaO_2 at about − 70° and −40° were established by the method of low-temperature X-ray analysis described by Golder [26], and X-ray powder photographs are given for these temperature ranges. Todd [25] found two maxima at −77° and −50° on the curve for heat capacity plotted against temperature which can be explained by these transitions, and Carter and Templeton [22] determined the structures of these low-temperature modifications: NaO_2 in the form that exists below −80° has the structure of marcasite with the parameters a= 4.26 A, b= 5.54 A, and c= 3.44 A; NaO_2 in the form existing between −80° and −43° has a pyrite structure with the parameter a= 5.46 A; and, as stated above, at above −43° NaO_2 has a disordered pyrite structure. At −80°, i.e., at the transition temperature, Neiding and Kazarnovsky [27] found a maximum on the curve for the dependence of magnetic susceptibility on temperature.

The transition temperatures given by various authors vary from −70° [24] to −80° [23] and from −40° [24] to −50° [22, 25]. The entropy of Na_2O is 27.9 cal/ mole· degree at 298.16°K [25]. The specific heat of NaO_2 has been measured at various temperatures by Vedenеev and Skuratov [28] and by Todd [25].

The question of the existence of the compound Na_2O_3 still remains open. Joannis [29] states that he obtained Na_2O_3 in admixture with sodium peroxide by oxidizing a solution of sodium in liquid ammonia, but de Forcrand [30] and Kraus and Whyte [31] have thrown some doubt on Joannis' results.

By tensimetric analysis, Raikhshtein and Kazarnovsky [31, 33] have shown that no intermediate potassium trioxide (K_2O_3) is formed in the thermal decomposition of potassium superoxide. In the present investigation it is shown that no compound of composition Na_2O_3 is formed in the thermal decomposition of NaO_2, but this does not enable us to deny altogether the possibility of its existence under other conditions. By way of example we may cite chromium dioxide [34], which is not formed in the thermal decomposition of chromic anhydride under the usual conditions, but can be obtained at high pressures.

EXPERIMENTAL

We have carried out a physicochemical investigation (chemical, thermal, and X-ray analyses, determination of composition-temperature curves and decomposition polytherms) on sodium peroxide and superoxide, and we have obtained the composition-temperature diagram for the system $NaO_2 - Na_2O$. The decomposition polytherms were determined both by continuous measurements of loss in weight on a thermobalance and also by volumetric measurement of the oxygen evolved during the recording of the thermograms.

A detailed description of the prodcedure is given in previous papers [35, 36]. All the weighed samples for investigation were taken in a chamber in which the air was purified from moisture and carbon dioxide by means of suitable absorbents (P_2O_5, Na_2O_2, and KO_2). In the course of work with these samples, they were again isolated from the action of moisture and atmospheric carbon dioxide.

Investigation of Sodium Peroxide

The sodium peroxide preparation taken for investigation had the composition Na_2O_2 97.52%, NaOH 1.49%, and Na_2CO_3 0.99%. As this preparation contained 1.49% of hydroxide impurity, which could itself give thermal effects, we determined the differential thermogram of NaOH, which is shown in Fig. 1. The following heat effects a are to be observed on the thermogram. There is an effect at 60-65°, due to the fusion of sodium hydroxide monohydrate, observed visually. This effect is not accompanied by change of composition, this fact being shown by the curve for weight loss against temperature, which we determined by continuous weighing of the sample on a thermobalance during heating. Beginning from 123° the thermogram shows a drawn-out endothermic effect having a gentle maximum; this effect corresponds to the continuous removal of water from the melt. On the curve for weight loss against temperature, beginning from 124°, i.e. in the region of this effect, a loss in weight is observed, which confirms that the effect corresponds to removal of water from the substance. There are then two large superimposed effects on the thermogram at 280-295° and 305-314°. The first of these corresponds to the transition of the α-modification of NaOH into the β-modification, and the second corresponds to the melting of the β-modification [37]. The results of Smothers and coworkers [38] on the thermal analysis of sodium hydroxide are close to those obtained by us.

Fig. 2 shows the differential thermogram for sodium peroxide (Curve 1) and the simultaneously determined (from the volume of evolved oxygen) decomposition polytherm (Curve 2). The abscissas on both curves represent time (minutes), and the ordinates are: Curve 1, temperature difference between sample and standard (magnesium oxide) and Curve 2, milliliters of oxygen evolved in the given interval of time, reduced to standard conditions (STP).

On the thermogram for sodium peroxide (Fig. 2, Curve 1) there are at first two small endothermic effects, beginning at 275° and 287°. These effects are analogous to those on the NaOH thermogram (Fig. 1) and correspond to a polymorphous change followed by melting of the impurity. The lowering of the melting point of the hydroxide is probably due to the fact that it is not now present in the pure state, but only as an impurity in Na_2O_2. Further along the thermogram (Fig. 2) there is an endothermic effect at 510° corresponding to the melting of the peroxide. In the literature either a lower melting point of 460° is reported [5, 6], or it is stated that the peroxide does not melt, but decomposes [8, 9]. The decomposition polytherms (Fig. 2, Curve 2) show that at first, approximately from 380° to 510° (section a-b), there is only slight decomposition of solid peroxide with evolution of oxygen (about 0.02 atom per molecule). At 510° Na_2O_2 melts, as indicated by the endothermic effect on the thermogram. The slow decomposition of the peroxide continues also in the liquid state up to about 535° (Curve 2, section b-c), after which the rate of decomposition increases (section c-d) until at 545° vigorous evolution of the remaining active oxygen occurs with formation of solid sodium oxide (section d-e). Corresponding to this last process there is an endothermic effect beginning at 545° on the thermogram (Fig. 2, Curve 1). This effect passes over into an exothermic effect, and we have shown that this arises from interaction between the oxide formed and the Pyrex glass of the vessel. We have observed a similar process in an investigation of Li_2O_2 [35, 36]. The occurrence of an analogous effect when the thermogram is determined in a stainless steel beaker showed that Na_2O, unlike Li_2O [35, 36], reacts not only with glass, but also with stainless steel, and only by the use of nickel beakers was it found possible to avoid any interaction, as indicated by the associated exothermic effect on the thermograms.

Investigation of Sodium Superoxide

The compositions of the sodium superoxide preparations studied were:

No.	NaO_2 (%)	Na_2O_2 (%)	NaOH + Na_2CO_3 (%)
1	76.60	21.95	1.55
2	86.63	12.88	1.89

Fig. 1. Thermogram of sodium hydroxide.

Fig. 2. Thermogram (Curve 1) and decomposition polytherm (Curve 2) for sodium peroxide.

Since sodium peroxide is a decomposition product of the superoxide, its presence does not affect the form of the thermograms obtained. In the X-ray photographs obtained from both of the original preparations both NaO_2 lines and Na_2O_2 lines were observed. The compositions given later for intermediate decomposition products (ranging down to Na_2O_2) are referred by calculation to pure sodium superoxide.

Fig. 3 gives the thermogram and decomposition polytherm for Preparation No. 1, and Fig. 4 gives these curves for Preparation No. 2. On the thermogram for Preparation No. 1 (Fig. 3, Curve 1), the following effects are observed. At about 120° a fairly large endothermic effect begins; it corresponds to the decomposition of NaO_2 with formation of a continuous series of solid solutions up to a limiting composition corresponding to $Na_2O_{2.05}$; this follows from the continuous course of the decomposition polytherm for sodium superoxide as far as the composition indicated in the section a-b (Curve 2). X-ray investigations on Preparation No. 2 before and after being heated in a Stepanov vessel for 26 hours in the vapor of boiling xylene (138°), i.e., at a temperature corresponding to the field of existence of these solid solutions, showed a small shift in the interference lines (see Table 1), which confirmed the results of polythermal analysis.

Table 1 shows that there is a reduction in the parameters of the elementary cell, which corresponds to the formation of "deficiency" solid solutions, which is exactly what occurs in the present case.

Fig. 3. Thermogram (Curve 1) and decomposition polytherm (Curve 2) for sodium superoxide.

Fig. 4. Thermogram (Curve 1) and decomposition polytherm (Curve 2) for sodium superoxide.

TABLE 1

Interplanar Distances of Preparation No. 2 Before and After Being Heated at 138°

Interplanar Distances d		Difference	
Original superoxide	After being heated at 138°	Absolute	Relative (%)
3.0739	3.0636	0.0103	3.3
2.7670	2.7559	0.0111	4.0
2.5689	2.5571	0.0118	4.6
1.9584	1.9406	0.0158	8.1
1.8211	1.8054	0.0157	8.6
1.6698	1.6475	0.0138	8.3
1.5976	1.5834	0.0142	9.1
1.2701	1.2586	0.0115	9.6
1.0607	1.0470	0.0137	12.9

The thermogram (Fig. 3, Curve 1) shows that, beginning at 250°, there is a second large endothermic effect, which is accompanied by vigorous evolution of oxygen. The almost vertical section b-c on the decomposition polytherm (Curve 2), which is found in the region of this effect, indicates that the effect corresponds to the decomposition of the solid solution of limiting composition to Na_2O_2. Chemical analyses on the products formed by heating sodium superoxide above 320°, i.e. above the temperature of the effect under consideration, confirm that the decomposition product is sodium peroxide. Moreover, on X-ray powder photographs the superoxide lines disappear and only lines due to sodium peroxide remain. We observed no effects on the thermograms and no retardation on the decomposition polytherms in the region of the composition Na_2O_3. This indicates that, in the thermal decomposition of NaO_2, no compound of composition Na_2O_3 is formed, the limiting solid solution $Na_2O_{2.60}$ being decomposed directly to Na_2O_2.

Above 380° slow evolution of oxygen from sodium peroxide begins (section d-e, Curve 2). This evolution is not accompanied by any appreciable thermal effect. At about 460° (point e, Curve 2) there is an increase in the rate of oxygen evolution, and from this temperature onward sodium oxide, formed by decomposition of the peroxide, reacts, as we have shown, with the Pyrex glass of the vessel. On the thermogram this process corresponds to a small exothermic effect at 460-510°. At 510° the thermogram shows a large endothermic effect due to the fusion of undecomposed Na_2O_2. Between 510° and 545° the decomposition of the peroxide continues in the fused state (section f-g, Curve 2). At 545° the thermogram shows an endothermic effect and the decomposition polytherm indicates a second vigorous evolution of gas (section g-h); this effect conesponds to the decomposition of the remaining melt with evolution of the whole of the active oxygen and formation of solid Na_2O.

This effect passes over immediately into a large exothermic effect at 560-585°, which corresponds to interaction between the sodium oxide formed and the Pyrex glass of the vessel, as we have established previously in the investigation of Na_2O_2.

Fig. 4 shows the thermogram (Curve 1) and decomposition polytherm (Curve 2) for sodium superoxide preparation No. 2. Comparison of the thermograms for the two preparations (Curve 1, Fig. 3 and Curve 1, Fig. 4) shows that there is an additional small exothermic effect at 85-95° on the thermogram of the second preparation (Fig. 4).

The X-ray diagram of a preparation maintained at 100° for two hours showed that it was still the same sodium superoxide but in the form of considerably larger crystals, this fact being indicated by breaks in the continuity of the interference lines of the X-ray powder photograph. This implies that the exothermic effect found at 85-95° (Fig. 4) corresponds to the coarsening of the crystals of NaO_2. In the remaining sections of the thermograms and decomposition polytherms Preparations No. 1 and 2 behave almost identically. A certain difference is observed in that the large exothermic effect due to the interaction between the sodium oxide formed and the Pyrex glass of the vessel begins in preparation No. 2 immediately after the fusion effect, and the endothermic effect corresponding to the vigorous decomposition of the residual peroxide melt (occurring here at 547°) is, as it were, wedged into the large exothermic effect.

The overall composition of preparations at the point of fusion (516°) was found to vary fairly considerably, namely from $Na_2O_{1.88}$ (for the original Na_2O_2) to $Na_2O_{1.72}$ (for the peroxide preparation obtained by heating superoxide No. 2), but the melting point remained almost constant. This indicates constancy in the composition of the liquid phase, corresponding to the composition Na_2O_2.

Fig. 5. Thermograms for sodium superoxide recorded without protection from atmospheric moisture: a) in a quartz beaker: b) in a nickel beaker.

Fig. 6. Composition-temperature diagram for the system NaO_2—Na_2O obtained at a rate of heating of 5.5–6° per minute.

Fig. 5 gives two thermograms recorded in open beakers without protection from atmospheric moisture and carbon dioxide. The first (Fig. 5 a) was obtained in a quartz beaker, and the second (Fig. 5 b) in a nickel beaker. In both thermograms, in addition to the usual effects for NaO_2 at about 130° and at 250°, there were two small endothermic effects at 282° and 300° and at 290° and 310°, respectively. These effects correspond to the polymorphous change and subsequent fusion of NaOH impurity formed by reaction of the preparation with atmospheric moisture, as we have shown previously in the investigation of Na_2O_2. These effects were not observed on thermograms recorded in Stepanov vessels (Fig. 3 and 4, since the samples were then isolated from the effect of atmospheric moisture.

In Fig. 5 a there are two large exothermic effects beginning at 418° and 513° which are absent in Fig. 5b. The first of these effects corresponds to interaction between the glass of the vessel and NaOH impurity formed by heating NaO_2 in presence of atmospheric moisture, and the second corresponds to interaction between the glass and sodium oxide formed by the decomposition of residual peroxide. These effects are not observed on the thermogram recorded in open nickel beakers (Fig. 5 b), since neither NaOH [37] nor Na_2O reacts with nickel. This thermogram shows that they do not react even at high temperatures.

The Na_2O_2 fusion effect occurs at 510° in Fig. 5 b and at 505° in Fig. 5 a. The lowering of melting point when the thermogram was recorded in an open quartz beaker is probably due to the admixture of the sodium silicate formed.

A comparison of curves for weight loss as a function of temperature determined continuously with the aid of a thermobalance for the superoxide heated 1) in a current of dry oxygen and 2) in an atmosphere of dry CO_2-free air showed that air lowers the decomposition temperature both of NaO_2 itself and of the intermediate products.

On thermograms recorded in Stepanov vessels the decomposition temperatures are close to those obtained in a stream of oxygen. The explanation is that, during the determination, the samples are in an atmosphere of the oxygen evolved in the decomposition of the preparations, which displaces the air initially present in the vessels.

Composition-Temperature Diagram for the System Sodium Superoxide – Sodium Oxide

Apart from the above-described investigations, we have determined the composition-temperature diagram for the system NaO_2–Na_2O. Weighed samples of NaO_2 preparations were heated in Stepanov vessels to temperatures ranging from 150° to 565°, thermograms and oxygen evolution being simultaneously recorded. When the thermograms had been recorded, the products were analyzed for active oxygen. X-ray diffraction photographs were taken of some of the samples.

TABLE 2

Composition-Temperature Diagram for the System NaO_2–Na_2O

Temperature (°C)	Composition	Temperature (°C)	Composition
100	$Na_2O_{3.89}$	294	$Na_2O_{2.69}$
122	$Na_2O_{3.87}$	304	$Na_2O_{2.69}$
143	$Na_2O_{3.84}$	354	$Na_2O_{2.69}$
152	$Na_2O_{3.90}$	386	$Na_2O_{1.98}$
164	$Na_2P_{3.97}$	408	$Na_2O_{1.97}$
190	$Na_2O_{3.94}$	432	$Na_2O_{1.88}$
208	$Na_2O_{3.79}$	452	$Na_2O_{1.94}$
221	$Na_2O_{3.78}$	488	$Na_2O_{1.88}$
230	$Na_2O_{3.79}$	510	$Na_2O_{1.86}$
244	$Na_2O_{3.68}$	526	$Na_2O_{1.78}$
254	$Na_2O_{3.69}$	546	$Na_2O_{1.78}$
262	$Na_2O_{3.72}$	554	$Na_2O_{1.71}$
266	$Na_2O_{3.80}$	558	$Na_2O_{1.69}$
272	$Na_2O_{3.64}$	568	$Na_2O_{1.88}$
274	$Na_2O_{2.44}$	572	$Na_2O_{1.58}$ + silicate
280	$Na_2O_{2.53}$	583	$Na_2O_{1.58}$ + silicate
284	$Na_2O_{2.68}$	592	Sodium silicate

A comparative examination of all our results enabled us to construct the composition-temperature diagram for the system NaO_2–Na_2O, which we give in Fig. 6. The corresponding numerical data are given in Table 2.

This is not an equilibrium diagram, but corresponds to a rate of heating of 5.5-6° per minute. The region of the diagram corresponding to solid solutions is shaded.

In the section a-b (100-250°) there is a continuous series of solid solutions having a limiting composition corresponding to the formula $Na_2O_{3.69}$ and having the lattice of NaO_2. As already stated, the X-ray powder photographs showed displacement of the interference lines (see Table 1).

At 250° the limiting solid solution begins to decompose vigorously to give Na_2O_2. This begins to decompose slightly to sodium oxide already in the solid state at temperatures from 380° to 510° (section d-f). At 510° sodium peroxide melts and its slow decomposition continues also in the liquid state up to 545°. At this temperature vigorous decomposition of residual liquid peroxide occurs with formation of solid Na_2O. Between 510° and 545° there is a heterogeneous region on the diagram corresponding to mixture of sodium peroxide melt and solid sodium oxide.

SUMMARY

1. It was shown that NaO_2 begins to decompose at about 120° in an atmosphere of dry oxygen and at about 80-90° in an atmosphere of dry CO_2-free air. In the course of its thermal decomposition it gives a continuous series of solid solutions up to the limiting composition of $Na_2O_{3.69}$.

2. $Na_2O_{3.69}$ decomposes vigorously and endothermically into Na_2O_2 at about 250° in oxygen and about 215° in dry CO_2-free air.

3. Slight decomposition of Na_2O_2 is observed in the solid state from 300° upward. At 510° Na_2O_2 melts. At 545° there is vigorous decomposition of residual liquid peroxide with formation of solid Na_2O. Between 510° and 545° there is a heterogeneous region on the diagram corresponding to Na_2O_2 melt and solid Na_2O. The latter reacts exothermically with the glass or stainless steel of the vessel, but does not react with nickel.

4. The existence of the following phases of constant composition was established for the system NaO_2–Na_2O: three modifications of NaO_2 having transition temperatures of −80° and −45°, Na_2O_2, and Na_2O. Phases of variable composition were found ranging from Na_2O_2 to $Na_2O_{2.25}$. We were unable to establish the formation of the compound Na_2O_3 under our conditions.

SCISSION OF THE CARBON – CARBON BOND IN COMPOUNDS CONTAINING THE TRIPHENYLMETHYL GROUP

A. N. Nesmeyanov, V. F. Lavrushin, T. M. Shmaeva, and E. G. Perevalova

In a study of compounds of the type $[(CH_3)_2NC_6H_4]_2C-CH_2-Y=X$ it has been shown that the bond attaching tris(p-dimethylaminophenyl)methyl with the rest of the molecule is very labile and is readily broken by the action of carboxylic acids and magnesium bromide with formation of Crystal violet in the case of 3,3,3-tris(p-dimethylaminophenyl)propionaldehyde, 3,3,3-tris(p-dimethylaminophenyl)-2-methylpropionaldehyde, 5,5,5-tris(p-dimethylaminophenyl)-2-pentenal, and 1,1,1-tris(p-dimethylaminophenyl)-2-nitroethane, i.e. compounds in which the $>C-CH_2-$ bond is conjugated with a C=O or N=O bond. In the case of allyltris(p-dimethylaminophenyl)methane and tris(p-dimethylaminophenyl)propylmethane, no Crystal violet could be isolated [1, 2].

In the present investigation we have made a spectrophotometric study of solutions of 3,3,3-tris(p-dimethylaminophenyl)propionaldehyde, allyltris(p-dimethylaminophenyl)methane, and tris(p-dimethylaminophenyl)propylmethane after treatment with acetic, chloroacetic, and trichloroacetic acids, and we have also measured the absorption spectra of these compounds in some polar solvents (acetic anhydride, bromobenzene, and nitrobenzene).

As shown previously [1], when boiled with acetic acid, 3,3,3-tris(p-dimethylaminophenyl)propionaldehyde is completely converted into Crystal violet. It was shown in the present investigation that chloroacetic and trichloroacetic acids act similarly.

3,3,3-Tris(p-dimethylaminophenyl)propionaldehyde was heated with chloroacetic and trichloroacetic acids at 100°. The resulting solutions were diluted with ethanol for absorption spectrum measurements. When the aldehyde was heated with acetic and chloroacetic acids there was an intense bluish-violet coloration, but when it was heated with trichloroacetic acid the solution became orange-yellow, but turned bluish-violet when diluted with ethanol.

The absorption curves for these bluish-violet solutions were almost identical with the curve for Crystal violet, as can be seen from Fig. 1. It must be pointed out that, even in the case of trichloroacetic acid (when the auxochromes are partially excluded from conjugation), acidolysis occurs. Fig. 2 gives the absorption curves for solutions of the aldehyde in acetic anhydride, bromobenzene, and nitrobenzene. As they are all completely identical with the curve for Crystal violet, we consider that, under the influence of polar solvents, dissociation occurs with formation of the Crystal violet cation.

It was of great interest to examine the behavior of allyltris(p-dimethylaminophenyl)methane and tris(p-dimethylaminophenyl)propylmethane, for which no scission products were isolated. The absorption curves for allyltris(p-dimethylaminophenyl)methane given in Fig. 3 show that this compound is also partially split by treatment with acetic and trichloroacetic acids with formation of Crystal violet. The absorption curves for solutions in acetic anhydride and bromobenzene are similar.

Tris(p-dimethylaminophenyl)propylmethane behaved differently. Even when this substance was boiled in polar solvents for a long time, no coloration appeared; this result indicates absence of scission of the molecule. Hence, in tris(p-dimethylaminophenyl)propylmethane the bond formed by tris(p-dimethylaminophenyl)methyl with propyl is less labile than the corresponding bond in allyltris(p-dimethylaminophenyl)methane and the aldehyde studied. In our opinion this results from the absence in the propyl group of a double bond conjugated with the methane C–C linkage.

The absorption curves of ethanol solutions of tris(p-dimethylaminophenyl)propylmethane that had been treated with acetic and trichloroacetic acids were found to be different in character, as can be seen from Fig. 4. It is possible that in this case the linkage to one of the benzene rings is broken, as observed by one of us in a series of arylmethanes [3-5].

Fig. 1. Absorption curves for solutions of 3.3.3-tris(p-dimethylaminophenyl)propionaldehyde: 1) in CH_3COOH; 2) in $CH_2ClCOOH$ + C_2H_5OH; 3) in CCl_3COOH + C_2H_5OH; 4) aqueous Crystal violet in H_2O.

Fig. 2. Absorption curves for solutions of 3.3.3-tris(p-dimethylaminophenyl)propionaldehyde: 1) in $(CH_3CO)_2O$; 2) in C_6H_5Br; 3) in $C_6H_5NO_2$; 4) aqueous Crystal violet in H_2O.

Fig. 3. Absorption curves for solutions of allylidene-(p-dimethylaminophenyl)methane: 1) in CH_3COOH; 2) in CCl_3COOH + C_2H_5OH; 3) in $(CH_3CO)_2O$; 4) in C_6H_5Br; 5) aqueous Crystal violet in H_2O.

Fig. 4. Absorption curves for solutions of tris(p-dimethylaminophenyl)propylmethane: 1) in CH_3COOH; 2) in $CH_2ClCOOH$ + C_2H_5OH; 3) Malachite green in C_2H_5OH.

The results we have given present a qualitative picture of the behavior of the compounds under investigation in their interactions with acids and when dissolved in polar solvents. In order to characterize these processes quantitatively, we have carried out experiments to determine the extent to which the molecules of these compounds are broken down under various conditions.

EXPERIMENTAL

An exactly weighed sample of the substance to be investigated was dissolved in a suitable solvent, and the solution was heated or was maintained at room temperature. For optical-density measurements, these solutions were diluted with ethanol in the case of acetic, chloroacetic, and trichloroacetic acids, or with the solvent used in the preparation of the original solution — in the other cases. The extent to which the molecules of the compounds were broken down (α) was calculated from the value of the molar extinction coefficient determined for a wavelength in the region of the absorption maximum of the principal band of the compound. The results are given in the table.

* CrV = $[(CH_3)_2N{-}C_6H_4]_3{-}C{-}$.

The data given in the table on the degree of acidolysis or dissociation of the compounds studied show that the C—CH_2 bond is most mobile in the aldehyde, less mobile in allyltris(p-dimethylaminophenyl)methane, and only very slightly mobile in tris(p-dimethylaminophenyl)propylmethane.

It is probable that, when there is a unified conjugated chain, scission of the C—C bond will occur between the methane carbon and the electron-accepting substituent.

When no such conjugated chain is present, the scission must occur at the bond with the electron-donating substituent:

This conclusion requires further experimental confirmation.

SUMMARY

1. Absorption spectra were measured for 3,3,3-tris(p-dimethylaminophenyl)propionaldehyde, allylbis(p-dimethylaminophenyl)methane, and tris(p-dimethylaminophenyl)propylmethane as solutions in polar solvents and after interaction with acetic, chloroacetic, and trichloroacetic acids.

2. On the basis of the photospectrometric data it was shown that scission of a C—C bond occurs in the first two compounds under the action of acids and polar solvents, but in the third only under the action of acids.

3. It was shown how the scission of the C—C bond depends on the character of the conjugation in the molecules of the compounds investigated.

ALLYL REARRANGEMENT IN SOME SUBSTITUTED POLYHALOALLYL ALCOHOLS

L. I. Zakharkin

Allyl anionotropic rearrangement of substituted allyl alcohols containing halogen at the double bond has been studied in detail only for the monochloro derivatives $RR'C(OH)CH=CHCl$, which give α,β-unsaturated aldehydes by rearrangement [1-3]. As regards dichloro derivatives of allyl alcohols, it has been noted that, for example, 1,1-dichloro-3-methyl-1-nonen-4-yn -3-ol cannot undergo rearrangement into the corresponding unsaturated acid [2]. 1,1,3-Trichloropropene [4] and 1,1,3-trichloro-2-methylpropene [5], which contain the system $ClC-C=CCl_2$, are also found to be incapable of the allyl rearrangement. It was of interest to make a more detailed investigation of the possibility of allyl rearrangement of polyhaloallyl alcohols (and their ethers) in accordance with the following schemes:

$$RR'C(OH)CH=CX_2 \longrightarrow [RR'C=CHCX_2OH] \longrightarrow RR'C=CH-COOH;$$
(I)

$$RR'C(OH)CX=CHX \longrightarrow [RR'C=CX-CHXOH] \longrightarrow RR'C=CX-CHO;$$
(II)

$$RR'C(OH)CX=CX_2 \longrightarrow [RR'C=CX-CX_2OH] \longrightarrow RR'C=CX-COOH,$$
(III)

in which X is a halogen.

Compounds of formula (I) in which the substituents are alkyl groups were found to be incapable of rearrangement, even under severe conditions. When 1,1-dichloro-1-hepten-3-ol was heated for a long time with 10% sulfuric acid in aqueous alcohol or aqueous dioxane, it was recovered unchanged, and its ethyl ether was recovered similarly when it was heated in acetic acid solution. In an acid medium 4,4-dichloro-2-methyl-3-buten-2-ol readily eliminated water with formation of 1,1-dichloro-3-methyl-1,3-butadiene, but its methyl ether, heated with 10% sulfuric acid in aqueous-alcoholic solution, was recovered unchanged. Compounds of formula (I) in which R is aryl and R' is hydrogen are readily rearranged in an acid medium into 3-arylacrylic acids:

$$ArCH(OH)-CH=CCl_2 \xrightarrow[H_2O]{H^+} ArCH=CH-COOH$$
(or an acetic acid)

The reaction was carried out by heating an acetic acid solution of the aryl derivative with hydrochloric acid. The aryl substituents studied were phenyl, p-tolyl, 1-naphthyl, and p-chlorophenyl*. However, 4,4-dichloro-2-phenyl-3-buten-2-ol did not undergo rearrangement either under these conditions or when treated with 10% sulfuric acid in aqueous-alcoholic solution; only elimination of water occurred with formation of 1,1-dichloro-3-phenyl-1,3-butadiene:

* The rearrangement of some of these compounds has been published previously by the author in collaboration with Nesmeyanov and Freidlina [6].

When heated, this product dimerized and lost a molecule of hydrogen chloride, giving a compound of composition $C_{10}H_5Cl_5$.

The presence of a negative substituent in compounds of formula (I) inhibits anionotropic rearrangement even when the displacement of the double bond permits the formation of a conjugated system. Thus, when 4, -dichloro-2-ethoxy (or hydroxy)-3-butenenitrile was heated in an acid medium, no anionotropic allyl rearrangement occurred with formation of fumaric acid, but only hydrolysis of the nitrile group to carboxyl occurred. On the other hand, 4,4-dichloro-2-ethoxy-3-butenenitrile readily underwent prototropic allyl rearrangement under the action of triethylamine with formation of 4,4-dichloro-2-ethoxycrotonitrile [7]. When heated in dilute hydrochloric acid, this product underwent an interesting conversion into 3-chloroacrylic acid:

$$CCl_2{=}CH{-}\underset{\displaystyle OC_2H_5}{\underset{|}{CH}}{-}CN \xrightarrow{(C_2H_5)_3N} CHCl_2{-}CH{=}\underset{\displaystyle OC_2H_5}{\underset{|}{C}}{-}CN \xrightarrow[H_2O]{H^+} [CHCl_2CH_2COCN] \rightarrow$$

$$\rightarrow CHCl{=}CH{-}COOH + HCN$$

The synthesis of compounds of formula (I) was carried out as follows: 4,4-dichloro-2-methyl-3-buten-2-ol was prepared by the action of methylmagnesium iodide on 4,4-dichloro-3-buten-2-one; 1,1-dichloro-1-hepten-3-ol, 1,1-dichloro-3-ethoxy-1-heptene, 1-aryl-3,3-dichloro-2-propen-1-ols, and 3-aryl-1,1-dichloro-3-ethoxypropenes were prepared by the action of the corresponding organomagnesium compounds on 3,3-dichloroacrolein or 1,1,3-trichloro-3-ethoxypropene:

$$RMgX + CCl_2{=}CH{-}\underset{\displaystyle OC_2H_5}{\underset{|}{\overset{\displaystyle Cl}{\overset{|}{CH}}}} \longrightarrow R{-}\underset{\displaystyle OC_2H_5}{\underset{|}{CH}}{-}CH{=}CCl_2$$

3,3-Dichloro-1-p-chlorophenyl-2-propen-1-ol was prepared as indicated:

The 3,3-dichloroacrylic acid required for this reaction was prepared by the oxidation of 3,3-dichloroacrolein with chromic anhydride in acetone solution. 4,4-Dichloro-2-ethoxy-3-butenenitrile was prepared by the action of cuprous cyanide on 1,1,3-trichloro-3-ethoxypropene.

With respect to allyl rearrangement, compounds of formula (II) behaved similarly to the compounds (I). When there were alkyl substituents rearrangement did not occur, even under severe conditions. When treated with 10% sulfuric acid in aqueous-alcoholic solution at room temperature, 1,2-dibromo-1-hexen-3-ol, 1,2-dibromo- and 1,2-dichloro-3-methyl-1-penten-3-ols, and 1-(1,2-dibromovinyl)cyclohexanol were unaffected (recovered unchanged), and when heat was applied elimination of water or resinification resulted. 2,3-Dichloro-1-phenyl-2-propen-1-ol and the acetic ester of 2,3-dibromo-1-phenyl-2-propen-1-ol readily underwent rearrangement into the corresponding α-halocinnamaldehyde when heated in acetic acid solution in presence of hydrochloric acid:

$$C_6H_5CH(OH){-}CCl{=}CHCl \xrightarrow[H_2O]{H^+} C_6H_5CH{=}CCl{-}CHO$$

2,4 Dibromo-2-phenyl-3-buten-2-ol, like 4,4-dichloro-2-phenyl-3-buten-2-ol, does not undergo rearrangement in an acid medium, but eliminates water. It is interesting to note that 4-chloro-2-phenyl-3-buten-2-ol is rearranged into the corresponding aldehyde [3]. The behavior of 2,3-dibromo-1,1-diphenyl-2-propen-1-ol in an acid medium possessed several peculiarities: when it was treated in acetic acid solution with hydrochloric or hydrobromic acid,

the product first formed was 1,2-dibromo-3-chloro- or 1,2,3 tribromo 3,3 diphenylpropene, respectively, which, when heated in 90% acetic acid solution, was converted not into 2-bromo-3,3-diphenylacrolein, but into 1,2-dibromo-3-phenylindene, although both of these trihalo compounds, and also 2,3-dibromo-1,1-diphenyl-2-propen-1-ol, gave the 2,4-dinitrophenylhydrazone of 2-bromo-3,3-diphenylacrolein when treated with 2,4-dinitrophenylhydrazine in alcoholic solution in presence of sulfuric acid. 1,2-Dibromo-3-phenylindene was formed immediately from 2,3-dibromo-1,1-diphenyl-2-propen-1-ol when this was treated in acetic acid solution with sulfuric, or better, perchloric acid:

The formation of 1,2-dibromo-3-phenylindene can be represented as follows:

The structure of 1,2-dibromo-3-phenylindene follows from its conversion into o-benzoylbenzoic acid by permanganate oxidation. Compounds of formula (II) were prepared by addition of bromine to the corresponding acetylenic alcohols.

The possibility of rearrangement in the system $RR'C(OH)CX=CX_2$ was investigated for the case of 2,3,3-trichloro-1-phenyl-2-propen-1-ol. When this substance was heated in acetic acid solution in presence of hydrochloric acid, it was converted into α-chlorocinnamic acid:

$$C_6H_5CH(OH)-CCl=CCl_2 \xrightarrow[H_2O]{H^+} C_6H_5CH=CCl-COOH$$

This rearrangement went much less readily than that of 3,3-dichloro-1-phenyl-2-propen-1-ol: 75% conversion of the 2,3,3-trichloro compound into α-chlorocinnamic acid required heating for 25 hours, whereas the 3,3-dichloro compound was converted completely into cinnamic acid in 30-40 minutes. 2,3,3-Trichloro-1-phenyl-2-propen-1-ol, was prepared by the reduction of 2,3,3-trichloroacrylophenone with aluminum isopropoxide.

EXPERIMENTAL

4,4-Dichloro-2-methyl-3-buten-2-ol. 4,4-Dichloro-3-buten-2-one was prepared from 1,1-dichloroethylene and acetyl chloride [2]. It was allowed to stand, when hydrogen chloride was eliminated and a solid was found; m.p. 66-67° (from petroleum ether-benzene mixture); b.p. 173-174° (8 mm).

Found %: C 46.47; 46.70; H 2.67; 2.86; Cl 34.74; 34.96

$C_5H_6Cl_2O_2$. Calculated %: C 46.62; H 2.92; Cl 34.63

Found: M 202.5 (cryoscopically in benzene)

Calculated: M 205

4,4-Dichloro-3-buten-2-one (28 g) was added to a stirred ethereal solution of methylmagnesium iodide (prepared from 32 g of methyl iodide and 5.6 g of magnesium in 70 ml of ether). The reaction mixture was heated for one hour, cooled, and decomposed with ammonium chloride solution. The ethereal solution was dried with potassium carbonate. Vacuum distillation yielded 22.4 g (78%) of 4,4-dichloro-2-methyl-3-buten-2-ol, b.p. 60-61° (20 mm); n_D^{25} 1.4780; d_4^{20} 1.2220; Found MR 35.91; Calculated MR 36.08.

Found %: C 38.92; 38.86; H 7.41; 7.38

$C_5H_8Cl_2O$. Calculated %: C 38.71; H 7.89

When the 4,4-dichloro-2-methyl-3-buten-1-ol was allowed to stand, water was eliminated. It was allowed to stand in an aqueous-alcoholic solution of sulfuric acid (10%), and on the next day an oil had separated, which was extracted with ether. Distillation gave 1,1-dichloro-3-methyl-1,3-butadiene, b.p. 34-35° (11 mm) and n_D^{20} 1.5030. No senecioic acid was detected.

1,1-Dichloro-1-hepten-3-ol. A solution of 15 g of 2,3-dichloroacrolein in 30 ml of ether was added to butylmagnesium bromide, prepared from 22 g of butyl bromide and 3.6 g of magnesium. The reaction mixture was heated for one hour, cooled, and decomposed with ammonium chloride solution. Vacuum distillation gave 17.8 g of 1,1-dichloro-1-hepten-3-ol, b.p. 103-104° (8 mm); n_D^{23} 1.4791; d_4^{20} 1.1431; Found MR 45.40; Calculated MR 45.22.

Found %: C 45.72; 45.70; H 6.68; 6.71
$C_7H_{12}Cl_2O$. Calculated %: C 45.90 H 6.55

When a solution of 1,1-dichloro-1-hepten-3-ol in 10% sulfuric acid was heated for 24 hours, no 2-heptenoic acid was obtained, the original compound being recovered unchanged.

3,3-Dichloroacrylic Acid. A solution of 25 g of chromic anhydride in a mixture of 40 g of concentrated sulfuric acid and 90 ml of water was added gradually to a cooled solution of 37.5 g of 2,3-dichloroacrolein in 120 ml of acetone. When the oxidation was complete, 100 ml of water was added and the mixture was extracted with chloroform. The chloroform extract was extracted with a dilute solution of caustic alkali. The alkaline solution was acidified with hydrochloric acid, and 3,3-dichloroacrylic acid was precipitated; further amounts of the acid were obtained by extraction of the aqueous solution with ether. The total yield of 3,3-dichloroacrylic acid was 24.8 g (59%); m.p. 76-77°.

3,3,4'-Trichloroacrylophenone. 3,3-Dichloroacryloyl chloride was prepared in 85% yield by heating 3,3-dichloroacrylic acid with excess of thionyl chloride; it boiled at 143-144°. Aluminum chloride (7 g) was added gradually to a stirred mixture of 8.5 g of 3,3-dichloroacryloyl chloride and 12 g of chlorobenzene, and the mixture was heated for 15-20 minutes at 70-80°. The mixture was cooled and decomposed with ice water. Vacuum distillation gave 10.1 g of 3,3,4'-trichloroacrylophenone, b.p. 168-169° (8 mm) and m.p. 51-52° (from petroleum ether).

Found %: C 45.65; 45.78; H 2.02; 2.04
$C_9H_5Cl_3O$. Calculated %: C 45.88; H 2.12

3,3-Dichloro-1-p-chlorophenyl-2-propen-1-ol. A mixture of 10 g of 3,3,4'-trichloroacrylophenone, 12 g of aluminum isopropoxide, and 80 ml of isopropyl alcohol was heated, acetone being allowed to distil off. When the reduction was complete, the mixture was carefully decomposed with dilute sulfuric acid. The reaction product was extracted with chloroform and dried with potassium carbonate. Vacuum distillation gave 8.1 g of 3,3-dichloro-1-p-chlorophenyl-2-propen-1-ol, b.p. 142-143° (3 mm); n_D^{20} 1.5730; d_4^{20} 1.3998; Found MR 55.90; Calculated MR 55.72.

Found %: C 45.25; 45.38; H 2.90; 2.81
$C_9H_7Cl_3O$. Calculated %: C 45.47; H 2.94

p-Chlorocinnamic Acid. Heating of a solution of 3,3-dichloro-1-p-chlorophenyl-2-propen-1-ol in acetic acid containing hydrochloric acid for one hour gave a 92% yield of p-chlorocinnamic acid, m.p. 244-245° (from glacial acetic acid); the literature [6] gives m.p. 245°.

4,4-Dichloro-2-phenyl-3-buten-2-ol. A solution of 13 g of 4,4-dichloro-3-buten-2-one in 15 ml of ether was added to a cooled stirred ethereal solution of phenylmagnesium bromide (from 17 g of bromobenzene and 2.7 g of magnesium in 40 ml of ether). The reaction mixture was heated for 20 minutes, cooled, and decomposed, with ammonium chloride solution. The ethereal solution was dried with potassium carbonate. Vacuum distillation in a current of nitrogen gave 14.8 g (72%) of 4,4-dichloro-2-phenyl-3-buten-2-ol, b.p. 186-187° (2 mm); n_D^{20} 1.5574; d_4^{20} 1.2567; Found MR 55.65; Calculated MR 55.67.

4,4-Dichloro-2-ethoxy-3-butenenitrile. A mixture of 62 g of 1,1,3-trichloro-3-ethoxypropene and 40 g of cuprous cyanide was heated with stirring at 130-160° for four hours. The reaction mixture was cooled, chloroform was added, and the whole was transferred to a Wurtz flask. Solvent was removed under somewhat reduced pressure, and the nitrile was then distilled off from the copper salts. Redistillation yielded 51 g of 4,4-dichloro-2-ethoxy-3-butenenitrile, b.p. 84-85° (8 mm); n_D^{20} 1.4642; d_4^{20} 1.2160; Found MR 40.90; Calculated MR 40.64.

Found %: N 7.56; 7.68
$C_6H_7Cl_2NO$. Calculated %: N 7.77

In a similar way, 3-butoxy-1,1,3-trichloropropene gave 2-butoxy-1,1,3-trichloropropene, b.p. 102-103° (5 mm); n_D^{20} 1.4635; d_4^{20} 1.1443; Found MR 50.11; Calculated MR 49.87.

Found %: N 6.85; 6.92
$C_9H_{13}Cl_3NO$. Calculated %: N 6.73

4,4-Dichloro-2-ethoxy-3-butenoic Acid. A solution of 20 g of 4,4-dichloro-2-ethoxy-3-butenenitrile in a mixture of 60 ml of acetic acid, 30 ml of concentrated hydrochloric acid, and 30 ml of water was boiled for ten hours. Acetic acid was then distilled off under reduced pressure. A little water was added to the residue, and the oil that separated was extracted with chloroform. The product (20 g) was 4,4-dichloro-2-ethoxy-3-butenoic acid, b.p. 114-115° (2 mm); n_D^{20} 1.4899; d_4^{20} 1.3445; Found MR 42.71; Calculated MR 42.35.

Found %: C 39.52; 39.54; H 4.41; 4.56
$C_6H_8Cl_2O_3$. Calculated %: C 39.34; H 4.37

No fumaric acid could be found in the hydrolysis products.

4,4-Dichloro-2-ethoxycrotononitrile. A few drops of triethylamine were added to 20 g of 4,4-dichloro-2-ethoxy-3-butenenitrile. The mixture became appreciably warm. On the next day the reaction product was vacuum-distilled, the product being 19 g of 4,4-dichloro-2-ethoxycrotononitrile, b.p. 86° (10 mm); n_4^{20} 1.4797; d_4^{20} 1.2074. A second treatment with triethylamine did not affect the constants.

Found %: N 7.62; 7.73
$C_6H_7Cl_2NO$. Calculated %: N 7.77

In a similar way 2-butoxy-4,4-dichloro-3-butenenitrile was isomerized into 2-butoxy-4,4-dichlorocrotononitrile, b.p. 96-97° (4 mm); n_D^{20} 1.4760; d_4^{20} 1.1347

Found %: N 6.72; 6.68
$C_9H_{13}Cl_2NO$. Calculated %: N 6.73

3-Chloroacrylic Acid. A mixture of 28 g of 4,4-dichloro-2-ethoxycrotononitrile, 150 ml of water, and 5 ml of concentrated hydrochloric acid was refluxed for three hours. Hydrogen cyanide was evolved. After being cooled, the solution was extracted with ether. The product (12.2 g) was 3-chloroacrylic acid, m.p. 85-95° (from petroleum ether); the literature [9] gives m.p. 85-86°.

1,2-Dibromo-3-methyl-1-penten-3-ol. This was prepared in almost quantitative yield by treatment of an illuminated solution of 3-methyl-1-penten-3-ol in carbon tetrachloride with bromine at 35-40°; it had b.p. 98-99° (7 mm); n_D^{20} 1.5380; d_4^{20} 1.7417; Found MR 64.34; Calculated MR 64.80.

Found %: C 27.82; 28.01; H 3.81; 3.71
$C_6H_{10}Br_2O$. Calculated %: C 27.90; H 3.87

After it had been allowed to stand in aqueous-alcoholic 10% sulfuric acid for ten days at room temperature, it was recovered from the mixture unchanged.

A solution of 40 g of 1,2-dibromo-3-methyl-1-penten-3-ol in a mixture of 80 ml of glacial acetic acid, 7 ml of concentrated hydrochloric acid, and 10 ml of water was heated for two hours. An oil separated, and when the reaction mixture was cool it was diluted with water and extracted with chloroform. Vacuum fractionation gave two fractions: Fraction I, b.p. 43-45° (2 mm) and n_D^{20} 1.5340-1.5417, 14.2 g; and Fraction II, b.p. 80-86° (2 mm) and n_D 1.5590, 9.8 g. Fraction II was found to be 1,2-dibromo-3-methyl-1,3-pentadiene (or its isomer), b.p. 88-89° (7 mm); n_D^{20} 1.5641; d_4^{20} 1.6863.

Found %: C 30.55; 30.25; H 3.37; 3.45
$C_6H_8Br_2$. Calculated %: C 30.00 H 3.33

Fraction I was a mixture containing a small amount of carbonyl compound, since it formed a 2,4-dinitrophenylhydrazone, m. p. 194-197° (from glacial acetic acid), which did not contain halogen.

1,2-Dibromo-1-hexen-3-ol. Treatment of an illuminated solution of 20 g of 1-hexyn-3-ol in 50 ml of carbon tetrachloride with bromine at 30° gave 26.3 g of 1,2-dibromo-1-hexen-3-ol, b.p. 78-79° (1 mm); n_D^{20} 1.5390; d_4^{20} 1.7414; Found MR 64.36; Calculated MR 64.50.

Found %: C 28.11; 28.08; H 3.92; 3.98

After the 1,2-dibromo-1-hexen-3-ol had been allowed to stand for a week in aqueous alcoholic 10% sulfuric acid, the whole of it was recovered unchanged b.p. 112-113°(8 mm). No aldehyde was detected.

1-(1,2-Dibromovinyl)cyclohexanol. This was prepared in almost quantitative yield by treatment of an illuminated solution of 1-ethynylcyclohexanol with bromine at 45-50°; b.p. 128-129° (5 mm); m.p. 73-74° (from aqueous alcohol).

Found %: C 33.66; 33.58; H 4.17; 4.12
$C_8H_{12}OBr_2$. Calculated %: C 33.80; H 4.23

When a solution of 37 g of 1-(1,2-dibromovinyl)cyclohexanol in a mixture of 80 ml of acetic acid, 5 ml of concentrated hydrochloric acid, and 10 ml of water was heated for one hour, an oil separated. The reaction mixture was cooled, diluted with water, and extracted with chloroform. Vacuum fractionation gave 12.3 g of a fraction having b.p. 87-90° (8 mm), n_D^{20} 1.5560; d_4^{20} 1.2915, and containing a small amount of a carbonyl compound, since a 2,4-dinitrophenylhydrazone (m. p. 240-241° from glacial acetic acid) was obtained; the carbonyl compound did not contain halogen.

Acetic Ester of 2,3-Dibromo-1-phenyl-2-propen-1-ol. Addition of 18 g of bromine to 17 g of the acetic ester of 1-phenyl-2-propyn-1-ol in carbon tetrachloride solution gave 28 g of the acetic ester of 2,3-dibromo-1-phenyl-2-propen-1-ol, b.p. 139-140° (1.5 mm); n_D^{20} 1.5752; d_4^{20} 1.6705; Found MR 66.14; Calculated MR 66.01.

Found %: C 39.67; 39.56; H 3.06; 3.13
$C_{11}H_{10}Br_2O_2$. Calculated %: C 39.52; H 2.99

The addition of bromine to 1-phenyl-2-propyn-1-ol itself did not proceed altogether smoothly, for water and hydrogen bromide separated in the reaction.

α-Bromocinnamaldehyde. A solution of 10 g of the acetic ester of 2,3-dibromo-1-phenyl-2-propen-1-ol in a mixture of 40 ml of acetic acid, 3 ml of concentrated hydrochloric acid, and 5 ml of water was heated for one hour. Dilution of the cooled reaction mixture with water gave a precipitate of 5.8 g (95%) of α-bromocinnamaldehyde, m.p. 70-71° (from alcohol); oxime, m.p. 135-136°.

2,3-Dichloro-1-phenyl-2-propen-1-ol. This was prepared in low yield by addition of chlorine to 1-phenyl-2-propyn-1-ol in carbon tetrachloride solution. It had b.p. 105-106° (3 mm); n_D^{20} 1.5723; d_4^{20} 1.3226; Found MR 50.56; Calculated MR 50.95.

Found %: C 52.95; 52.98; H 3.69; 3.76
$C_9H_8Cl_2O$. Calculated %: C 52.30; H 3.94

α Chlorocinnamaldehyde. A solution of 5 g of 2,3-dichloro-1-phenyl-2-propen-1-ol in acetic acid containing hydrochloric acid was heated for one hour. The product (3.2 g) was α-chlorocinnamaldehyde, b.p. 122-123° (9 mm); oxime, m.p. 158-159°.

3,1-Dibromo-2-phenyl-3-buten-2-ol. This was prepared in almost quantitative yield by treating an illuminated solution of 2-phenyl-3-butyn-2-ol in carbon tetrachloride with bromine at 45-55°. It had b.p. 134-135° (2 mm); n_D^{30} 1.6061; d_4^{20} 1.7217; Found MR 61.37; Calculated MR 61.37

Found %: C 39.01; 39.08; H 3.12; 3.09
$C_{10}H_{10}Br_2O$. Calculated %: C 39.21; H 3.26

When it was heated in acetic acid solution in presence of hydrochloric acid, the corresponding aldehyde was not formed.

2,3-Dibromo-1,1-diphenyl-2-propen-1-ol. 1,1-Diphenyl-2-propyn-1-ol was prepared by the action of sodium acetylide on benzophenone in liquid ammonia. When treated in alcoholic solution with 2,4-dinitrophenylhydrazine in presence of sulfuric acid, 1,1-diphenyl-2-propyn-1-ol was converted almost quantitatively into the 2,4-dinitrophenylhydrazone of 3,3-diphenylacrolein, m.p. 196-197° (from acetic acid).

A solution of 4 g of bromine in 10 ml of carbon tetrachloride was added to an illuminated solution of 5 g of 1,1-diphenyl-2-propyn-1-ol in 30 ml of carbon tetrachloride. The solution was boiled for one hour under illumination, and was then cooled and washed with sodium carbonate solution. A solid remained after removal of solvent. The yield of 2,3-dibromo-1,1-diphenyl-2-propen-1-ol was 8 g; m.p. 112-113° (from a mixture of benzene and petroleum ether).

Found %: C 49.39; 49.30; H 3.29; 3.40
$C_{15}H_{12}Br_2O$. Calculated %: C 49.20; H 3.28

Treatment of 2,3-dibromo-1,1-diphenyl-2-propen-1-ol in alcoholic solution with 2,4-dinitrophenylhydrazine in presence of sulfuric acid gave the 2,5-dinitrophenylhydrazone of 2-bromo-3,3-diphenylacrolein, m.p. 245-246° (from acetic acid).

Found %: N 11.90; 11.76
$C_{21}H_{15}BrN_4O_4$. Calculated %: N 11.98

When concentrated hydrochloric acid was added to a hot solution of 2,3-dibromo-1,1-diphenyl-2-propen-1-ol in acetic acid, after a few minutes there was a crystalline precipitate of 1,2-dibromo-3-chloro-3,3-diphenylpropene, m.p. 137-138° (from acetic acid).

Found %: C 46.15; 46.19; H 2.87; 2.97
$C_{15}H_{11}Br_2Cl$. Calculated %: C 46.50; H 2.86

In a similar way, reaction with hydrobromic acid gave 1,2,3-tribromo-3,3-diphenylpropene, m.p. 152-153° (from acetic acid).

Found %: C 41.98; 42.90; H 2.53; 2.48
$C_{15}H_{11}Br_3$. Calculated %: C 41.78; H 2.55

1,2-Dibromo-3-phenylindene. A few drops of 70% perchloric acid were added to a warm solution of 5 g of 2,3-dibromo-1,1-diphenyl-2-propen-1-ol in 20 ml of acetic acid, and the mixture was heated for a few minutes at 105-110°. When the mixture cooled, a crystalline precipitate (3.2 g) of 1,2-dibromo-3-phenylindene formed; m.p. 82-83° (from alcohol).

Found %: C 51.17; 51.19; H 3.00; 3.06; Br 45.72
$C_{15}H_{10}Br_2$. Calculated %: C 51.42; H 2.86; Br 45.71

When a solution of 1,2,3-tribromo-3,3-diphenylpropene in 90% acetic acid was boiled for several hours, 1,2-dibromo-3-phenylindene was again obtained; m.p. 82-83° (from alcohol). The product showed no melting point depression in admixture with the 1,2-dibromo-3-phenylindene obtained in the preceding experiment.

Oxidation of 2.2 g of 1,2-dibromo-3-phenylindene with potassium permanganate (3.2 g) in presence of magnesium oxide in aqueous-acetone solution at room temperature gave 0.8 g of o-benzoylbenzoic acid, m.p. 127-128° (from benzene). The product showed no melting point depression in admixture with o-benzoylbenzoic acid prepared from phthalic anhydride and benzene.

2,3,3-Trichloro-1-phenyl-2-propen-1-ol. A mixture of 15 g of 2,3,3-trichloroacrylophenone, 15 g of aluminum isopropoxide, and 50 ml of isopropyl alcohol was heated for five hours, acetone being distilled off. The reaction mixture was decomposed cautiously with dilute sulfuric acid, and was extracted with chloroform. Vacuum distillation gave 13.2 g of 2,3,3-trichloro-1-phenyl-2-propen-1-ol, b.p. 119-113° (1.5 mm); n_D^{20} 1.5820; d_4^{20} 1.4225; Found MR 55.72; Calculated MR 56.72.

Found %: C 45.72; 45.69; H 2.99; 3.09

$C_9H_7Cl_3O$. Calculated %: C 45.47; H 2.94

α-Chlorocinnamic Acid. Heating of an acetic acid solution of 5 g of 2,3,3-trichloro-1-phenyl-2-propen-1-ol in presence of hydrochloric acid for four hours gave 0.1 g of α-chlorocinnamic acid, m.p. 139-140° (from petroleum ether). When the mixture was heated for 25 hours, the yield of α-chlorocinnamic acid was 75%.

SUMMARY

1. A study was made of the possibility of allyl anionotropic rearrangement in the systems $RR'C(OH)CH{=}CX_2$, $RR'C(OH)CX{=}CHX$ and $RR'C(OH)CX{=}CX_2$, X being halogen. It was shown that when the substituents are alkyl groups rearrangement does not occur.

2. It was shown that rearrangement occurs in these systems when R = Ar and R' = H.

3. It was found that $CCl_2{=}CH{-}CH(OC_2H_5)CN$ does not undergo allyl anionotropic rearrangement, but readily undergoes allyl prototropic rearrangement in presence of triethylamine.

ORGANOBORON COMPOUNDS

COMMUNICATION 5. PREPARATION OF ISOBUTYL ESTERS OF BENZENEBORONIC AND DIPHENYLBORINIC ACIDS WITH THE AID OF PHENYLLITHIUM

B. M. Mikhailov and P. M. Aronovich

In a previous paper [1] we have described the reactions of phenyllithium with isobutyl esters of boric acid and benzeneboronic acids, which result in the formation of complex salts: lithium triisobutoxy(phenyl)borate and lithium diisobutoxydiphenylborate*. Further study of these reactions has shown that they can be applied to the preparation of benzeneboronic acid (or its esters) and esters of diphenylborinic acid.

It was found that, as might be expected, lithium triisobutoxy(phenyl)borate (I) is converted by treatment with mineral acids into benzeneboronic acid, but, in addition, a small amount (8%) of boric acid is formed. It is clear that the triisobutoxy(phenyl)boric acid (II) formed from the lithium salt (I) is decomposed with elimination of an alcohol or benzene with formation of esters of benzeneboronic or boric acid, respectively, this being then hydrolyzed to the corresponding acid:

When the products of the reaction between phenyllithium and triisobutyl borate are treated directly with hydrochloric acid, benzeneboronic acid can be obtained in 82% yield without isolating the salt (I). Also, if the reaction mixture is treated with dry hydrogen chloride, a good yield of diisobutyl benzeneboronate can be obtained.

The fact that the synthesis of an areneboronic ester from a trialkyl borate and an aryllithium passes through the stage of a salt of a complex boric acid suggests that the reaction between a trialkyl borate and an organomagnesium compound may occur by a similar mechanism and not as a metathetic reaction, as it has usually been regarded:

$$B(OAlk)_3 + RMgX \longrightarrow RB(OAlk)_2 + AlkOMgX.$$

The synthesis of boronic esters with the aid of Grignard reagents may then be expressed as follows:

$$B(OAlk)_3 + RMgX \longrightarrow [RB(OAlk)_3]^-MgX^+ \longrightarrow [RB(OAlk)_3]^-H_3O^+ \longrightarrow RB(OAlk)_2$$

* As there is no recognized system of nomenclature for compounds of this type, they are named here by an adaptation of the nomenclature for inorganic complex compounds. — Publisher.

Lithium diisobutoxydiphenylborate (III) differs greatly in properties from the complex borate (I). The complex salt (III) required for this investigation was prepared by the addition of lithium isobutoxide to isobutyl diphenylborinate, which was obtained by the action of phenylmagnesium bromide on triisobutyl borate [2]

$$[(C_6H_5)_2BOC_4H_9 + C_4H_9OLi \rightarrow [(C_6H_5)_2B(OC_4H_9)_2]^- Li^+ \qquad (III)$$

This method gives the complex borate (III) in the pure state and in high yield.

When an aqueous solution of lithium diisobutoxydiphenylborate (III) was treated with dilute hydrochloric acid, a mixture of isobutyl diphenylborinate and benzeneboronic acid was obtained, with a considerable preponderance of the second (28% and 62% yield respectively). The same results were obtained by decomposition of the products of reaction between phenyllithium and diisobutyl benzeneboronate with hydrochloric acid without isolation of the intermediate complex compound (III) in the pure state. Thus, the diisobutoxydiphenylboric acid (IV) formed by acidification of a solution of the salt (III) decomposes like the acid (II) with elimination of an alcohol or benzene, but in this case the second course of decomposition is predominant:

$$[(C_6H_5)_2B(OC_4H_9)_2]^- Li^+ \xrightarrow{HCl + H_2O} [(C_6H_5)_2B(OC_4H_9)_2]^- H_3O^+ \qquad (IV)$$

$$-C_4H_9OH \qquad -C_6H_6$$

$$28\% \qquad 62\%$$

$$(C_6H_5)_2BOC_4H_9 \qquad C_6H_5B(OC_4H_9)_2$$

Hence, replacement of isobutoxyl by phenyl in the acid (II) results in a great change in the properties of the acid. Whereas the course of the decomposition of triisobutoxy(phenyl)boric acid (II) is in full accord with the relatively high electronegative character of the isobutoxy radical (its greater tendency, as compared with that of phenyl, to separate as an ion) the anion of diisobutoxydiphenylboric acid (IV) eliminates the less electronegative phenyl as an ion with greater readiness.

With the object of determining the effect of the medium on the decomposition of the diisobutoxydiphenylborate anion, experiments were carried out on the effect of dry hydrogen chloride on the complex salt (III). It was found that, under these conditions, the salt (III) is converted mainly into the diphenylborinic ester (82% yield), the benzeneboronic ester being obtained in only 5% yield.

$$[(C_6H_5)_2B(OC_4H_9)_2]^- Li^+ \xrightarrow{HCl} [(C_6H_5)_2B(OC_4H_9)_2]^- H^+ \qquad (V)$$

$$-C_4H_9OH \qquad -C_6H_6$$

$$82\% \qquad 5\%$$

$$(C_6H_5)_2BOC_4H_9 \qquad C_6H_5B(OC_4H_9)_2$$

Hence, replacement of the ononium ion of diisobutoxydiphenylboric acid (IV) by a proton — the acid (V) — has a marked effect on the character of its decomposition.

This method — the decomposition of the complex borate (III) with dry hydrogen chloride — is of preparative importance. When the products of reaction between phenyllithium and a benzeneboronic ester are decomposed in this way, the pure diphenylborinic ester can be obtained in 70% yield without isolation of the salt (III).

EXPERIMENTAL

Action of Hydrochloric Acid on Lithium Triisobutoxy(phenyl)borate

To a solution of 6.28 g (0.02 mole) of lithium triisobutoxy(phenyl)borate (prepared by the addition of lithium isobutoxide to diisobutyl benzeneboronate [1]) in 10 ml of water, 3 ml of 30% hydrochloric acid was added, and the mixture was treated four times with ether. Ether was distilled from the extract, 15 ml of water was added to the residual solution, and isobutyl alcohol was distilled off together with the water. The residue was cooled, and the

precipitate of benzeneboronic acid was filtered off and dried (1.97 g); a further 0.22 g of benzeneboronic acid was extracted from the filtrate with ether. The total yield of benzeneboronic acid was 90%; the unpurified acid melted at 207-210°.

Caustic soda was added to the aqueous solution until it became weakly alkaline, and it was then evaporated down to about 10 ml. Methanol (20 ml) was added, the mixture was neutralized exactly with acid, and 2 g of mercuric chloride was added. The mixture remained neutral, so that benzeneboronic acid was absent. After addition of excess of mannitol, the boric acid present was titrated with caustic soda, the amount found being 0.097 g, i.e. 7.8%.

Benzeneboronic Acid and its Isobutyl Ester

A solution of phenyllithium prepared from 17.3 g (0.11 mole) of bromobenzene, 1.6 g of lithium, and 175 ml of ether was cooled to −5° and was then gradually cooled still further and stirred mechanically while addition was made of a solution of 23 g (0.1 mole) of triisobutyl borate in 50 ml of ether. The greater part of the solution was added at below −50°, the duration of the addition being 20-40 minutes. The reaction mixture was stirred for five hours at −70°, and was then left in a cooling bath. On the next day the mixture was acidified with 20% hydrochloric acid, the ether layer was separated, the aqueous layer was treated twice with ether, and solvent was distilled from the combined ethereal solutions. Water (50 ml) was added to the residue, and isobutyl alcohol was distilled off together with the water. The residue was cooled, and benzeneboronic acid was filtered off and dried. The yield was 10 g, i.e. 82%; the unpurified acid melted at 208-215°.

For the preparation of diisobutyl benzeneboronate, the reaction was carried out as described above, but the reaction mixture was saturated with dry hydrogen chloride, ether was distilled off, and the precipitate present was filtered off and washed with benzene. Isobutyl alcohol and benzene were distilled from the filtrate, and the residue was fractionally distilled, the product being 16 g (68%) of ester, b. p. 116-117° (5 mm) and d_4^{20} 0.9243.

Found %: C_6H_5 32.78; B 4.52

$C_6H_5B(OC_4H_9)_2$. Calculated %: C_6H_5 32.93; B 4.62

Lithium Diisobutoxydiphenylborate

In a nitrogen atmosphere, 11.5 ml (0.125 mole) of absolute isobutyl alcohol was added to 77 ml (0.1 mole) of a cooled (ice water) mechanically stirred 1.3 N benzene solution of butyllithium. To the resulting clear solution of lithium isobutoxide, which was again cooled with ice water, 26.2 g (0.11 mole) of isobutyl diphenylborinate diluted with 50 ml of ether was added over a period of 30 minutes. The resulting solution was stirred for three hours at 0°, and the solvent was distilled off under reduced pressure in a current of nitrogen. When the mass became thick, the capillary was raised and the nitrogen was passed above the mixture, the flask being heated in a boiling water bath. After the removal of solvents was complete, the residue was mixed with 50 ml of hexane and filtered. The residue was washed on the filter with 40 ml of hexane and vacuum-dried. The yield of lithium diisobutoxydiphenyl borate was 24.8 g (78%).

Found %: Li 2.24; C_6H_5 48.27; B 3.32

$(C_6H_5)_2B(OC_4H_9)_2Li$. Calculated %: Li 2.19; C_6H_5 48.46; B 3.40

Action of Hydrochloric Acid on Lithium Diisobutoxydiphenylborate

Hydrochloric acid (20%) was added to a cooled (ice water) stirred solution of 15.9 g (0.05 mole) of lithium diisobutoxydiphenylborate in 50 ml of ether until it reacted acid. The ether layer was separated, the aqueous layer was treated twice with ether, and ether and isobutyl alcohol were distilled from the ether extracts. The residue was mixed with 20 ml of isopentane and filtered; the residue of benzeneboronic acid was washed with isopentane and dried (yield 3.2 g). Isopentane was distilled from the filtrate, and vacuum distillation of the residue gave 3.3 g (27.8%) of isobutyl diphenylborinate, b. p. 142-145° (6 mm). A residue of 0.6 g of benzeneboronic acid remained in the flask; the total yield of benzeneboronic acid was 62.3%.

Action of Hydrogen Chloride on Lithium Diisobutoxydiphenylborate

Dry hydrogen chloride was passed through a solution of 15.9 g (0.05 mole) of lithium diisobutoxydiphenylborate in 50 ml of ether for one hour. Ether was distilled off, and the precipitate of lithium chloride was filtered off and washed with benzene. Distillation of the filtrate gave 10.3 g of a fraction boiling at 158-164° (8 mm).

Found %: C_6H_5 63.0; B 4.51.

Calculation showed that the mixture contained 0.87 g of $C_6H_5B(OC_4H_9)_2$ and 9.73 g of $(C_6H_5)_2BOC_4H_9$. The yield of diisobutyl benzeneboronate was thus 4.9%, and that of isobutyl diphenylborinate 81.7%.

Action of Phenyllithium on Diisobutyl Benzeneboronate

a) Decomposition with Hydrochloric Acid. Under the condition described above for the preparation of benzeneboronic acid, 23.4 g (0.1 mole) of diisobutyl benzeneboronate was added to an ethereal solution of phenyllithium prepared from 17.3 g (0.11 mole) of bromobenzene, 1.6 g of lithium, and 175 ml of ether. The resulting clear solution was acidified with 20% hydrochloric acid. Ether and isobutyl alcohol were distilled off, and the residue was vacuum-fractionated through a column, yielding Fraction I [0.9 g, b.p. 112-116° (6 mm).] which was a mixture of diphenyl with a little diisobutyl benzeneboronate, Fraction II [2.9 g, b.p. 117-119° (6 mm)], which was diisobutyl benzeneboronate, and Fraction III [b.p. 143-144° (6 mm).] which was isobutyl diphenylborinate, obtained in 26.1% yield (6.2 g). The residue in the flask (5.8 g) was benzeneboronic acid. The overall yield of benzeneboronic acid and its ester was 60.2%.

b) Decomposition with Hydrogen Chloride. Reaction between equimolecular amounts of diisobutyl benzeneboronate and phenyllithium was carried out as described above. The reaction mixture was saturated with hydrogen chloride, ether was distilled off, and lithium chloride was filtered off and washed with benzene. Benzene and isobutyl alcohol were distilled from the filtrate, and vacuum fractionation of the residue gave 1.91 g of Fraction I, boiling up to 152° (8 mm), and 16.97 g of Fraction II, b.p. 153-158° (8 mm).

Fraction I. Found %: C_6H_5 38.60; B 2.93
Fraction II. Found %: C_6H_5 62.50; B 4.53

$C_6H_5B(OC_4H_9)_2$. Calculated %: C_6H_5 32.93; B 4.62
$(C_6H_5)_2BOC_4H_9$. Calculated %: C_6H_5 64.75; B 4.54

Calculation shows that Fraction I contained 0.1 g of diisobutyl benzeneboronate and 1.1 g of isobutyl diphenylborinate, the remainder being biphenyl. Fraction II contained 1.2 g of $C_6H_5B(OC_4H_9)_2$ and 15.73 g of $(C_6H_5)_2BOC_4H_9$.

Hence, the yield of diisobutyl benzeneboronate was 1.3 g (5.5%), and the yield of isobutyl diphenylborinate was 16.9 g (71%). The analyses were carried out by the method of Wittig and coworkers [3]. All operations with phenyllithium were carried out in an atmosphere of dry nitrogen, and the complex compounds were isolated with exclusion of moisture.

SUMMARY

1. When lithium triisobutoxy(phenyl)borate was treated with hydrochloric acid, benzeneboronic acid and a little boric acid were formed.

2. When lithium diisobutoxydiphenylborate was treated with hydrochloric acid, the main product was benzeneboronic acid, isobutyl diphenylborinate being formed, but in smaller amount. In the decomposition of lithium diisobutoxydiphenylborate with hydrogen chloride, isobutyl diphenylborinate was formed almost exclusively.

3. In the reaction of triisobutyl borate with phenyllithium, the yield of benzeneboronic acid was 82%.

4. Reaction of diisobutyl benzeneboronate with phenyllithium, followed by decomposition of the reaction products with hydrogen chloride, resulted in the formation of isobutyl diphenylborinate in 70% yield.

ACYLATION OF AMINOALKYL-PHOSPHONIC AND -PHOSPHONOTHIONIC ACIDS WITH CHLOROFORMIC ESTERS

T. Ya. Medved and M. I. Kabachnik

Investigators have recently shown great interest in carbamic acid derivatives because of their physiological activity, which is often very specific. It appeared to us that it would be of interest to synthesize carbamic esters having various phosphorus-containing groups substituted in an N-alkyl radical. Compounds of this kind can be readily prepared from aminoalkylphosphonic acids [1] or their esters by acylation with chloroformic esters.

We have previously studied [2] the acylation of aminoalkylphosphonic acids and esters with the acid chlorides and anhydrides of carboxylic acids. They were found to be somewhat more difficult to acylate than the usual amino carboxylic acids, but reaction nevertheless proceeded fairly readily. We have found that chloroformic esters also react readily with aminoalkyl-phosphonic and -phosphonothionic esters. When the reaction is carried out in a benzene medium in presence of excess of pyridine, the phosphorus grouping is not affected and the corresponding carbamic acid derivatives are formed:

A few minutes after the addition of the chloroformic ester to the mixture of aminoalkyl-phosphonic or -phosphonothionic ester, pyridine, and benzene, pyridine hydrochloride begins to separate and gradually forms into crystals. If necessary in order to bring the reaction to completion, the mixture is heated at 60-70° for 20-30 minutes. After removal of excess of pyridine and pyridine hydrochloride by washing with water, drying of the benzene solution, removal of solvent by distillation, and vacuum distillation of the residue, (alkoxycarbonyl-amino)alkyl-phosphonic and -phosphonothionic esters are obtained, usually in 40-80% yield. The constants of the substances obtained are given in the table.

We showed, on the basis of one example, that free aminoalkylphosphonic acids can also be acylated with chloroformic esters, but the reaction must then be carried out under Schotten-Baumann conditions.

All of the urethans obtained are readily soluble in alcohol, ether, and other organic solvents, but, with the exception of No. 1 and 2, they are insoluble in water.

We have already described [1] the original aminoalkyl-phosphonic and -phosphonothionic esters. In the present investigation we have prepared also O,O-diethyl α-aminobenzylphosphonothionate, which was described previously only in the form of the picrate. The ester is readily isolated by treating the picrate with alkali and extracting the alkaline solution with ether. Its constants are given in the table (No. 11).

EXPERIMENTAL

1. Diethyl 1-(Methoxycarbonylamino)-1-methylethylphosphonate. Methyl chloroformate (1.2 g) was added dropwise to a mixture of 1.95 g of diethyl 1-amino-1-methylethylphosphonate, 15 ml of pyridine, and 20 ml of benzene. The reaction was carried out at 2-3°. As the chloroformic ester was added, crystals of pyridine hydrochloride began to be precipitated on the walls of the flask. When the separation of crystals stopped, they were removed from the solution. An equal volume of water was added to the solution, and the mixture was shaken vigorously. The benzene layer was separated, and the aqueous layer was again extracted with 10 ml of fresh benzene. The combined benzene layers were washed with a 5% solution of sodium carbonate and dried with sodium sulfate. Benzene was then distilled off, and the residue was vacuum-distilled.

The product, amounting to 0.54 g (21.3%), was a clear yellowish sirupy liquid, b.p. 104° (2 mm); n_D^{20} 1.4508; d_4^{20} 1.1507; Found MR 59.2; Calculated MR 59.9. It was soluble in water, alcohol, ether, and other organic solvents.

Found %: N 5.2; 5.4; P 12.1; 12.0
$C_7H_{18}NPO_3$. Calculated %: N 5.5; P 12.2

2. Diethyl 1-(Ethoxycarbonylamino)-1-methylethylphosphonate. This was prepared from a mixture of 5.85 g of diethyl 1-amino-1-methylethylphosphonate, 15 ml of pyridine, 30 ml of benzene, and 5.1 g of ethyl chloroformate. The reaction temperature was 5-8°. The procedure was as in the preceding experiment. The product, amounting to 5.65 g (70.5%), had b.p. 127-128° (3 mm); n_D^{20} 1.4497; d_4^{20} 1.1154; Found MR 64.4; Calculated MR 64.5. It was soluble in water, alcohol, ether, and other organic solvents.

Found %: C 45.1; 45.2; H 8.3; 8.5; N 5.2; 5.2; P 11.4; 11.4
$C_8H_{18}NPO_4$. Calculated %: C 44.9; H 8.3; N 5.2; P 11.6

3. Diethyl 1-(Isobutoxycarbonylamino)-1-methylethylphosphonate. This was prepared from a mixture of 1.95 g of diethyl 1-amino-1-methylethylphosphonate, 15 ml of pyridine, 30 ml of benzene, and 1.75 g of isobutyl chloroformate, which was heated for 30 minutes at a bath temperature of 50-60°. The further treatment of the reaction mixture was the same as in the preceding experiments. The product, amounting to 1.9 g (64%), boiled at 137-138° (3 mm). After being distilled, the substance solidified to crystals, m. p. 58-59°. This substance is insoluble in water, but readily soluble in alcohol, ether, and other organic solvents.

Found %: C 49.0; 49.2; H 8.7; 8.7; N 4.8; 4.8; P 10.3; 10.4
$C_{11}H_{24}NPO_4$. Calculated %: C 48.8; H 8.8; N 4.7; P 10.5

4. Diethyl α-(Methoxycarbonylamino)benzylphosphonate. This was prepared from 0.85 g of diethyl α-aminobenzylphosphonate, 5 ml of pyridine, 10 ml of benzene, and 0.4 g of methyl chloroformate. The product, amounting to 0.4 g (38%), was a colorless substance. It was recrystallized from ether; m.p. 104-106°. It did not dissolve in water, but was readily soluble in organic solvents.

Found %: C 52.2; 52.2; H 6.8; 7.0; P 10.5; 10.2
$C_{11}H_{16}NPO_5$. Calculated %: C 51.8; H 6.7; P 10.3

5. Diethyl α-(Ethoxycarbonylamino)benzylphosphonate. This was prepared from a mixture of 1.2 g of diethyl α-aminobenzylphosphonate, 7.5 ml of pyridine, 15 ml of benzene, and 0.75 g of ethyl chloroformate. The procedure was the same as in the preceding experiments. The residue remaining after removal of benzene was crystallized from ether, the product being 0.95 g (61%) of a colorless crystalline substance, m. p. 68-69°. This substance is not soluble in water, but readily dissolves in alcohol, ether, and other organic solvents.

Found %: C 53.5; 53.5; H 7.1; 7.3; N 4.3; 4.3; P 9.4; 9.4
$C_{12}H_{18}NPO_5$. Calculated %: C 53.3; H 7.0; N 4.4; P 9.8

6. Diethyl α-(Isobutoxycarbonylamino)benzylphosphonate. This was prepared from a mixture of 1.2 g of diethyl α-aminobenzylphosphonate, 7.5 ml of pyridine, 15 ml of benzene, and 0.87 g of isobutyl chloroformate, the procedure being the same as in the preceding experiments. The product, amounting to 0.85 g (50%), was a colorless sirupy liquid, b.p. 179° (3 mm). After being distilled, the substance solidified to crystals melting at 45-46°. This substance is insoluble in water, but readily soluble in alcohol, ether, and other organic solvents.

Found %: C 56.1; 55.9; H 7.6; 7.6; N 3.9; 4.0; P 8.7; 8.9
$C_{15}H_{24}NPO_5$. Calculated %: C 56.0; H 7.6; N 4.1; P 9.0

7. 0,0-Diethyl 1-(Ethoxycarbonylamino)-1-methylethylphosphonothioate. Ethyl chloroformate (1.5 g) was added dropwise to a mixture of 2.1 g of 0,0-diethyl 1-amino-1-methylphosphonothioate, 15 ml of pyridine, and 30 ml of benzene. The temperature of the reaction mixture then rose from 18° to 27°, and pyridine hydrochloride was gradually precipitated on the walls of the flask. The mixture was then heated in a bath for 30 minutes at 50-60°. When cool, the liquid was separated from the crystals and washed with an equal amount of water. The aqueous solution was extracted with a fresh portion of benzene. The combined benzene solutions were washed with 5% sodium carbonate solution and with water, and were then dried over sodium sulfate. The residue remaining after removal of benzene was vacuum-distilled and gave 1.6 g (57%) of a clear colorless liquid, b.p. 107-108° (3 mm); n_D^{18} 1.4788; d_4^{20} 1.1147; Found MR 72.0; Calculated MR 72.0. It did not dissolve in water, but was readily soluble in organic solvents.

Found %: C 42.1; 42.0; H 7.6; 7.8; N 4.7; 4.6; P 11.0; 11.3; S 11.0; 11.5

$C_{12}H_{28}NPSO_3$. Calculated %: C 42.4; H 7.8; N 4.9; P 10.9; S 11.3

8. 0,0-Diethyl 1-(Isobutoxycarbonylamino)-1-methylethylphosphonothioate. This was prepared from a mixture of 2.1 g of 0,0-diethyl 1-amino-1-methylethylphosphonothioate, 15 ml of pyridine, 30 ml of benzene, and 1.75 g of isobutyl chloroformate, the procedure being as in the preceding experiment. The product, amounting to 1.71 g (53%), was a clear colorless liquid, b.p. 120-123° (3 mm); n_D^{20} 1.4747; d_4^{20} 1.0792; Found MR 81.2; Calculated MR 81.2.

Found %: C 46.4; 46.2; H 8.2; 8.2; N 4.3; 4.3; P 9.3; 9.8; S 10.3; 10.4

$C_{12}H_{28}NPSO_3$. Calculated %: C 46.3; H 8.4; N 4.5; P 9.9; S 10.3

9. 0,0-Diethyl α-(Ethoxycarbonylamino)benzylphosphonothioate. This was prepared from a mixture of 1.3 g of 0,0-diethyl α-aminobenzylphosphonothioate, 7.5 ml of pyridine, 15 ml of benzene, and 0.75 g of ethyl chloroformate, the procedure being as in the preceding experiments. The product, amounting to 1 g (60%), boiled at 160° (3 mm) and melted at 49-50°. It was found to be insoluble in water, but readily soluble in alcohol, ether, and other organic solvents.

Found %: C 51.2; 51.0; H 6.8; 6.8; N 3.9; 3.7; P 9.2; 9.2; S 10.1; 10.2

$C_{14}H_{22}NPSO_4$. Calculated %: C 50.7; H 6.7; N 4.2; P 9.4; S 9.7

10. 0,0-Diethyl α-(Isobutoxycarbonylamino)benzylphosphonothioate. This was prepared from a mixture of 0.54 g of 0,0-diethyl α-aminobenzylphosphonothioate, 3 ml of pyridine, 6 ml of benzene, and 0.36 g of isobutyl chloroformate, the procedure being as in the preceding experiments. The product, amounting to 0.22 g (30.5%), was a colorless sirupy liquid, b.p. 158-160° (2 mm), n_D^{20} 1.5197; d_4^{20} 1.1308; Found MR 96.6; Calculated MR 98.1.

Found %: C 53.0; 52.9; H 7.2; 7.2; P 8.4; 8.2; S 9.3; 9.2

11. 0,0-Diethyl α-Aminobenzylphosphonothioate. A solution of 0.25 g of caustic soda in a mixture of 10 ml of ethanol and 10 ml of ether was added to 3 g of the picrate of 0,0-diethyl α-aminobenzylphosphonothioate [1], m.p. 176-178°. The mixture was heated in a bath for five minutes at 60-70°. When the mixture was cool, 3 ml of water was added (until the precipitate dissolved), and then 5 ml of ether. The mixture was agitated vigorously, the ether layer was separated, and the aqueous layer was again extracted with ether several times. The ether solution was washed with small portions of water until picric acid had been removed completely. It was then dried over sodium sulfate. After removal of ether, the residue was vacuum-distilled. The product, amounting to 1.1 g (68%), was a clear yellowish liquid, b.p. 129-130° (3 mm); n_D^{20} 1.5473; d_4^{20} 1.1478; Found MR 71.6; Calculated MR 71.2.

Found %: C 51.0; 51.0; H 6.9; 6.9; N 5.3; 5.2; P 12.1; 11.8; S 12.5; 12.8

SUMMARY

The introduction of N-alkoxycarbonyl into aminoalkyl-phosphonic and -phosphonothionic esters was investigated. It was found that reaction between aminoalkyl-phosphonic and -phosphonothionic esters and chloroformic esters in presence of pyridine resulted in the formation of the corresponding urethans.

PREPARATION AND REACTIONS OF SOME DERIVATIVES OF 3-UREIDONONANOIC ACID

V. M. Rodionov* and V. K. Zverykina

When amides of β-acylamino acids are treated with alkaline hypobromite, various complex and interesting reactions occur, which have been studied in our laboratory for various β-acylamino acid amides containing an aliphatic [1-3] or aromatic [4, 5] radical, and also for various acylureas. These investigations showed that it is possible to pass from β-amino acids to derivatives of imidazolidinone, hydantoin, oxadiazolinone, α-amino acids, and carboxylic acids. It was of interest to extend our study of the reaction to amides of β-ureido acids, in which, as a result of the action of hypobromite both on the amide and the ureide groups, the formation of heterocyclic compounds of the triazine and triazole series could be expected. With this object, we synthesized some amides of β-ureido, β-(3-alkylureido), and β-(3-arylureido) acids, which, for practical purposes, have not been described previously in the literature**.

Three methods are known for the preparation of ureido acids, and the yields obtained by the use of these usually range from 75% to 90%.

1) The general and very simple method due to Lendfeld and Stiegliz [8] (action of KCNO and RNCO on β-amino acids):

2) The long-known method due to Lippich [6] (heating the β-amino acid with a large excess of urea):

3) Our new method [9] for the preparation of β-ureido acids from amides of β-alkoxycarbonylamino acids by heating them with 5-10% caustic soda solutions:

The last method, which is somewhat more complicated than the others, has been used mainly for the characterization of β-amino acids, and also for the identification of synthesized compounds and the determination of their structures. It was of interest to extend this reaction to alkylated and arylated amides of β-alkoxycarbonylamino acids, and so make it possible to prepare β-(3-alkylureido) and β-(3-arylureido) acids without the use of alkyl and aryl isocyanates, which are not always readily accessible. Our experiments with the anilide and methylamide of 3-(ethoxycarbonylamino)nonanoic acid showed that the reaction is general and enabled us to extend its field of application. 3-(3-Alkylureido)- and 3-(3-arylureido)-nonanoic acids were prepared in 75-80% yield.

---

* Deceased.

** In 1952, in the preparation of 3-(2-naphthyl)-3-ureidopropionic acid by Lippich's method [6], Kurtev [7] noted the formation of about 4% of the amide of this acid.

For the preparation of amides of β-ureido acids we decided to use the synthesis via the acid chloride, which we have generally applied in the preparation of amides of acylated β-amino acids [10]. By this method we prepared amides of 3-ureido- and 3-(3-phenylureido) nonanoic acids in 70% yield. It is true that this reaction was accompanied by partial cyclization of the amide with elimination of ammonia and formation of a hydrouracil, but the compounds formed differed in properties and their separation presented no difficulty. 3-Ureidononanamide has a feebly alkaline reaction and is readily dissolved by 12% hydrochloric acid, from which it can be recovered unchanged by addition of caustic soda, whereas 6-hexylhydrouracil is a feebly acid substance, sparingly soluble in water and readily precipitated when its alkaline solution is acidified. A single recrystallization is sufficient to purify the substances obtained. For the separation of 3-(3-phenylureido)nonanamide and 6-hexyl-3-phenylhydrouracil, use was made of their differing solubility in alcohol.

In the Hofmann reaction with 3-ureidononanamide, a neutral substance melting at 121° was isolated for which elementary analysis and molecular weight determination suggested that its formula could be (I) or (II), on the assumption that the process occurs according to the following scheme:

Determination of active hydrogen by Terentyev's method confirmed the correctness of formula (I). The presence of an imidazolidinone ring in the compound isolated was established by acid and alkaline hydrolysis: in the first case 1,2-octanediamine was obtained, and in the second 4-hexyl-2-imidazolidinone. Apart from 1-carbamoyl-5-hexyl-2-imidazolidinone (I), an acidic amorphous substance containing nitrogen was also isolated. This substance was obtained in various experiments, and it had a rather wide, but always the same, decomposition temperature range, 127-160°. It corresponded in elementary composition to the formula $C_9H_{16}O_3N_2$.

EXPERIMENTAL

Preparation of 3-(Ethoxycarbonylamino)nonananilide. The ethoxycarbonyl derivative (2 g) was treated at 0° with 1.4 g of thionyl chloride, and the product was cooled while an ethereal solution of aniline was added. The anilide, amounting to 2.35 g (89%), melted at 152° (fine colorless needles from alcohol).

Found %: N 8.70; 8.66

$C_{20}H_{32}O_3N_2$. Calculated %: N 8.75

Preparation of 3-(3-Phenylureido)nonanoic Acid. a) Phenyl isocyanate (5.6 g) was added dropwise to 10 g of the amino acid in 100 ml of 12% caustic soda solution. On acidification, the ureido acid was precipitated in the form of an emulsion, which crystallized when allowed to stand. The product, amounting to 8.5 g (74%), melted at 106° (long colorless needles from aqueous alcohol).

Found %: N 9.57; 9.72

$C_{16}H_{24}O_3N_2$. Calculated %: N 9.59

b) 3-(Ethoxycarbonylamino)nonananilide (0.5 g) was boiled for seven hours with a 7.5% solution of caustic soda in 50% alcohol. The product was 0.34 g (80%) of 3-(3-phenylureido)nonanoic acid, m.p. 105°. In admixture with the product of Experiment a it melted at 105°.

Preparation of 3-(Ethoxycarbonylamino)-N-methylnonanamide. The methylamide was prepared under the same conditions as the anilide. From 1 g of the ethoxycarbonyl derivative, 0.72 g (69%) of the methylamide, m.p. 125°, was obtained (colorless flat needles from alcohol).

Found %: C 60.39; 60.70; H 10.21; 10.40; N 10.27

$C_{13}H_{26}O_3N_2$. Calculated %: C 60.48; H 10.08; N 10.85

Preparation of 3-(3-Methylureido)nonanoic Acid. The methylamide (0.1 g) was boiled for two hours with a 7% solution of caustic soda. Acidification of the cooled solution gave an emulsion, which crystallized by the next day. The product was 0.28 g (80.4%) of 3-(3-methylureido)nonanoic acid, m.p. 103-104° (long thin needles from water).

Found %: C 57.32; 57.75; H 9.67; 9.66; N 12.30; 12.28
$C_{11}H_{22}O_3N_2$. Calculated %: C 57.39; H 9.56; N 12.17

Preparation of 6-Hexyl-3-phenylhydrouracil. 3-(3-Phenylureido)nonanoic acid (1 g) was boiled for two hours with 20 ml of 17% hydrochloric acid. Evaporation of the solution gave 0.71 g (75%) of 6-hexyl-3-phenylhydrouracil, m.p. 210° (long needles from alcohol).

Found %: C 69.84; 70.04; H 8.32; 8.20; N 10.69
$C_{16}H_{22}O_2N_2$. Calculated %: C 70.09; H 8.03; N 10.22

Preparation of 3-(3-Phenylureido)nonanamide. A mixture of 4.6 g of the ureido acid and 5 ml of thionyl chloride was heated for three hours at 40°. The hydrochloride of the acid chloride was washed free from excess of thionyl chloride with absolute ether, and its suspension in ether was then saturated with ammonia. The precipitate was washed with 5% caustic soda solution and with water, and was then dried and recrystallized from alcohol, when 0.35 g (7.8%) of 6-hexyl-3-phenylhydrouracil, m.p. 209-210°, separated (a mixture with a sample from the preceding experiment melted at 210°). Dilution of the alcoholic mother liquor with water yielded 3.2 g (70%) of 3-(3-phenylureido)nonanamide, m.p. 158° (fine colorless needles from aqueous alcohol).

Found %: N 14.40; 14.53
$C_{16}H_{25}O_2N_3$. Calculated %: N 14.43

Preparation of 3-Ureidononanamide. The reaction conditions were the same as those of the preceding experiment, 9.7 g of the ureido acid and 3.5 ml of thionyl chloride being taken. In order to separate the amide from the hydrouracil, the product was treated with 12% hydrochloric acid: 0.42 g of 6-hexylhydrouracil, m.p. 187°, was obtained [1] (a mixture with a sample from the previous preparation melted at 187°). Addition of 40% caustic potash solution to the cooled hydrochloric acid solution gave 7.05 g (72%) of the amide, m.p. 198° (fine colorless needles from water).

Found %: C 56.10; H 9.56; N 19.30; 19.28
$C_{10}H_{21}O_2N_3$. Calculated %: C 55.81; H 9.72; N 19.53

Action of Hypobromite on 3-Ureidononanamide. The amide (10 g) was added in small portions to a stirred hypobromite solution cooled to a temperature of −5° to −10° (5.83 g of bromine in 160 ml of 12.8% caustic potash solution). After three hours the solution was warmed to 50°, when a spontaneous rise in temperature occurred with vigorous gas evolution and the precipitation of an oil. When the solution attained 65°, it was cooled and extracted with ether. At the boundary between the ether and the alkali solution there was an intermediate layer, from which an amorphous acid (decomposition temperature 127-160°) separated on acidification.

Found %: C 55.93; 56.34; H 8.37; 8.29; N 18.10; 18.04
$C_9H_{18}O_2N_2$. Calculated %: C 56.40; H 8.22; N 18.40

Acidification of the alkaline solution gave 0.36 g of 3-ureidononanoic acid, m.p. 127-128°, and 0.27 g of 6-hexylhydrouracil, m.p. 186-187° [1]. The ether solution gave a neutral, partially crystallizing oil, from which, by treatment with hot water, 1.61 g of 1-carbamoyl-5-hexyl-2-imidazolidinone, m.p. 121°, was obtained (colorless prismatic plates from water).

Found %: C 58.24; 58.96; H 8.22; 8.37; N 19.89; 19.74
$C_{11}H_{21}O_2N_3$. Calculated %: C 58.34; H 8.89; N 19.71

Found: M 219.8; 221 (in dioxane)
Calculated: M 212.9

$C_{11}H_{21}O_2N_3$. Calculated %: C 58.87; H 8.05; N 19.90; M 211

Estimation of active hydrogen atoms: 2.02 (in ether-pyridine); 1.89 (in ether).

Hydrolysis of 1-Carbamoyl-5-hexyl-2-imidazolidinone. When the substance was boiled for 30 hours with 10% caustic soda, the previously described 4-hexyl-2-imidazolidinone [1], m.p. 119°, was obtained, and when it was boiled for 20 hours with concentrated hydrochloric acid the previously described 1,2-octanediamine was obtained and was identified as its bisethoxycarbonyl derivative, m.p. 98° [2].

SUMMARY

1. The preparation of β-ureido acids from amides of β-(alkoxycarbonylamino) acids has been extended to alkylamides and arylamides. 3-(3-Methylureido)- and 3-(3-phenylureido)-nonanoic acids were prepared in 70-75% yield. A method of preparing amides of β-ureido acids was developed.

2. By reaction of 3-ureidononanamide with hypobromite, a neutral compound was obtained, which was shown to be 1-carbamoyl-5-hexyl-2-imidazolidinone.

INVESTIGATION OF HYDROGEN BONDING IN α-AMINONICOTINE BY THE METHOD OF COMPARING INFRARED ABSORPTION SPECTRA

Ya. L. Goldfarb, M. S. Kondakova, and D. N. Shigorin

As Goldfarb and Kondakova [1] have shown, the amino derivatives of nicotine (I) and (II)—α-aminonicotine [2-amino-3-(1-methyl-2-pyrrolidinyl)pyridine] and α'-aminonicotine [2-amino-5-(1-methyl-2-pyrrolidinyl) pyridine]—behave differently toward alkyl halides. In explanation of this difference, they suggested that, in α-aminonicotine (I), the spatial proximity of the amino group to the pyrrolidine ring makes it possible for intramolecular hydrogen bonding to occur, so that the reactivity of the pyrrolidine nitrogen of (I) is lowered.

(I) (II)

In order to determine whether this suggestion is in accord with actual behavior, we decided to compare the infrared absorption spectra of the bases (I) and (II) themselves and also of their salts (Ia), (IIa), and (III)*:

(Ia) (IIa) (III)

It would be expected that, if intramolecular hydrogen bonding occurs in α-aminonicotine (I), its spectrum will differ from those of its salts (Ia) and (III), in which the quadricovalent pyrrolidine nitrogen atom cannot form such a bond; and it would be expected also that there would be no great difference between the spectra of the salts (Ia) and (IIa). The presence of a hydrogen bond in the base (I) may be detected also when its spectrum is compared with that of α'-aminonicotine, in which such a bond cannot arise.

The results of measurements of the infrared spectra of these compounds in the NH_2-frequency region are given in Table 1. The synthesis and purification of these compounds, and the method of measurement have been given previously [2, 3, 5].

As will be seen from Table 1, the NH_2 group in crystalline α-aminonicotine is characterized by two bands, whereas it has four bands in the spectrum of crystalline α'-aminonicotine. The reduction of the number of bands of the first compound from four to two can be explained by the deformation of the group arising from the formation of an intramolecular hydrogen bond.

Similar phenomena are observed in the infrared absorption spectra of 1-aminoanthraquinones and o-amino azo compounds [6, 7].

The assignment of the wave numbers can be made as follows. The NH_2 group of crystalline α-aminonicotine participates, by means of one of its N–H links characterized by the wave number 3325 (10) cm^{-1}, in the formation

* The structures of the dihydrochlorides (Ia) and (IIa) as compounds arising by the addition of two protons to two ring nitrogen atoms, and of salt (III) as a pyrrolidinium iodide, were established previously [2–4].

TABLE 1

No.	Substance	Wave numbers for N—H bonds* (cm^{-1})
1	2-Aminopyridine (cryst.)	3448 (10, d), 3306 (5, d) 3170 (3, d)
2	α'-Aminonicotine (II) (cryst.)	3412 (10), 3315 (5), 3190 (4), 3130 (4)
	Solution in dioxane (1:20)	3480 (6), 3367 (10), 3222 (4)
	Solution in CCl_4 (1:20)	3485 (10), 3400 (5), 3320 (3), 3187 (1)
	Solution in CCl_4 (1:200)	3490 (8), 3400 (10), 3320 (2), 3185 (1)
3	α-Aminonicotine (I) (cryst.)	3325 (10), 3160 (5)
	Solution in dioxane (1:20)	3415 (10), 3290 (10), 3178 (1)
	Solution in CCl_4 (1:20)	3480 (10), 3290 (10, d) 3165 (3)
	Solution in CCl_4 (1:200)	3458 (8), 3292 (10, d) 3172 (1)
4	α-Aminonicotine methiodide (III) (cryst.)	3405 (5), 3310 (10), 3205 (3)
5	α-Aminonicotine dihydrochloride (Ia) (cryst.)	3425 (5), 3310 (3), 3180 (3), 3125 (2), 2560 (4) — diffuse band .... HCl
6	α'-Aminonicotine dihydrochloride (IIa) (cryst.)	3425 (10), 3345 (10), 3250 (10), 3110 (2), 2520 (3) — diffuse band .... HCl

* The numbers in parentheses express a qualitative estimate of the differential intensities of the bands; d denotes diffusion.

of an intramolecular hydrogen bond, and by means of the other N—H link — wave number 3160 (5) cm^{-1} — it participates also in an intermolecular, probably "twinning", hydrogen bond:

Such an association between α-aminonicotine molecules is most probable in the crystal. The band for the valency vibration of the N—H link at wave number 3160 cm^{-1} in the crystal has a considerable intensity and almost coincides with the wave number of the valency vibration of the N—H link in 2-aminopyridine*. In the latter compound the occurrence of intermolecular association has been established by cryoscopic measurements [5]. The correctness of this assignment of wave numbers is supported by the fact that with reduction in the concentration of a solution of α-aminonicotine in carbon tetrachloride the intensity of the 3160 cm^{-1} band sharply diminishes (see Table 1); and in dioxane, in which the double molecule is probably broken down, this band is almost completely absent. The formation of monomer by dilution is also evidenced by the appearance of a new band at 3480 cm^{-1}, which is not observed in the spectrum of the crystal and is probably to be assigned to the valency vibration of an N—H bond that does not take part in hydrogen-bond formation.

Cryoscopic measurements on benzene solutions of α-aminonicotine (see Table 2) indicate that only in comparatively concentrated solutions (about 1:19) are some of the molecules of this base associated by means of intermolecular hydrogen bonds. This probably results from the fact that the intramolecular hydrogen bond

must lie in the plane of the pyrrolidine and pyridine rings, so that the second N—H link

of the NH_2 group, which could participate in the intermolecular bond, must lie outside this plane, which will hinder the formation of a double molecule, which also requires the arrangement of the participating groups in one

* Analysis of the infrared absorption spectrum of the NH_2 group of this compound is given in the paper [3].

TABLE 2

α-Aminonicotine		α'-Aminonicotine	
Proportions of α-aminonicotine and benzene (by weight)	Molecular weight	Proportions of α'-aminonicotine and benzene (by weight	Molecular weight
1:100	180	1:105.6	175
		1:108	187
1:80.3	182	1:85	207
1:49.7	190	1:53.2	218
1:34.9	202	1:42.5	224
1:31	197	1:32.7	229
1:27.3	204	1:31.0	233
1:20.5	208	1:22.9	244
1:19.3	210	1:20	247

plane. Hence, intra- and inter-molecular hydrogen bonds are competing together. It must be supposed that, in the case under consideration, the first of these two types of bonds is the stronger, for the formation of such a bond results in the formation of an energetically favorable six-membered ring. On this account this type of bonding is preserved in solution.

The α-aminonicotine band at 3325 cm^{-1} is displaced only slightly toward the longer waves (to 3290 cm^{-1}) in the carbon tetrachloride solution; its intensity is almost independent of the concentration of the solution and its diffuse character is preserved; these peculiarities are characteristic for the presence of an intramolecular hydrogen bond [8-12]. Here it must be stated that, as already noted above, the spectrum of α'-aminonicotine, in which intramolecular hydrogen bonding is excluded, differs substantially from that of α-aminonicotine and is very close in character to that of 2-aminopyridine. In this case there is a band at about 3185 cm^{-1}, which, judging by its closeness to the 3180 cm^{-1} band of the α-isomer and the fact that its intensity is reduced by dilution of the carbon tetrachloride solution, must be assigned to an N—H link participating in a "twinning" bond. The high wave numbers, 3485 and 3400 cm^{-1}, in solutions characterize the antisymmetrical and symmetrical vibrations of the free NH_2 group, respectively, and the bands at 3315, 3320, and 3222 cm^{-1} probably correspond to the overtone of the deformational band. The band at 3412(10) cm^{-1} in crystalline α'-aminonicotine probably corresponds to the valency vibration of the N—H links concerned in the weaker interaction between the twinned double molecules, which results in the formation of larger aggregates.

The cryoscopic measurements on benzene solutions of α'-aminonicotine are in accord with the infrared absorption spectra of this substance. These measurements, as also the spectra, show the close resemblance in behavior between α'-aminonicotine and 2-aminopyridine, and the substantial difference in behavior between these compounds and α-aminonicotine. The infrared absorption spectra and the cryoscopic measurements show that the intermolecular bonding in solution is stronger for α'-aminonicotine than for α-aminonicotine. This may be explained by the competing effect of intramolecular hydrogen bonding in α-aminonicotine and the absence of this effect in α'-aminonicotine.

The question of hydrogen bonding in α-aminonicotine is resolved still more clearly when its spectra are compared with those of the corresponding pyrrolidinium iodide (III). As would be expected, the addition of methyl iodide to the pyrrolidine nitrogen of the base (I), which renders the maintenance of the intramolecular hydrogen bond impossible, results in a return to a system containing a "normal", undeformed group, so that the compound is spectally almost indistinguishable from 2-aminopyridine in the region of N—H frequencies. We here find coincidence both in number of bands and in frequencies.

In α-aminonicotine dihydrochloride (Ia), as in the methiodide (III), the amino group cannot take part in an intramolecular hydrogen bond. In a comparison of the spectra of this salt (Ia) and the original base (I), we therefore find a change in the N—H bands, both in their number and in their frequencies. On the other hand, in a comparison of the absorption of the N—H region for α'-aminonicotine and its dihydrochloride, no essential difference is to be noted (see Table 1) — nor, indeed, is there any essential difference between the spectra of the dihydrochlorides of the two isomeric bases. All of this is in complete accord with the concept of the presence of an intramolecular bond in α-aminonicotine.

SUMMARY

Investigation of aminonicotines and their hydrochlorides by the method of infrared absorption spectra showed:

1. The presence of an intramolecular hydrogen bond in α-aminonicotine. The wave number for the valency vibration of the N—H link participating in the intramolecular hydrogen bond is 3325 cm^{-1} in the crystal and 3290 cm^{-1} in carbon tetrachloride solution.

2. The intramolecular bond in α-aminonicotine is broken when hydrogen halide or methyl iodide adds to the pyrrolidine nitrogen.

3. The hydrochlorides of α- and α'-aminonicotines have similar spectra.

COMPOSITION OF THE THIOPHENE-GROUP COMPONENT OF THE GASEOUS PRODUCTS OF THE THERMAL DECOMPOSITION OF KASHPIR SHALES

Ya. L. Goldfarb, G. I. Gorushkina, and B. P. Fedorov

In the thermal decomposition of shales under the conditions applying at the Kashpir shale distillery, the products are: tar, containing, in particular, compounds of the thiophene series; semicoke; and gaseous decomposition products. The relatively high calorific value of this gas enables it to be used as furnace fuel. As the initial boiling temperature of Kashpir shale tar is about 125-127°, it is quite natural to suppose that much of the thiophene and its close homologs remain in the gas and are burnt in the furnaces. In order to determine the total content of these compounds in the products of the thermal decomposition of Kashpir shales*, we decided to separate the organic component (gas gasoline) from the so-called returned gas passing to the furnace burners and determine the individual and quantitative composition of the thiophene-group component**. With this object, we studied some samples of gas gasoline obtained at the Kashpir works by washing the returned gas from the retort furnaces with oil in a scrubber filled with Raschig rings. The shale-gas gasoline, separated from the oil absorbent by steam distillation, is a dark-brown liquid of unpleasant odor, boiling over the range of 40-200°, approximately. In Table 1 we give the characteristics of one of the several samples of gas gasoline that we investigated.

EXPERIMENTAL

In order to facilitate the solution of our problem, it was necessary to simplify the composition of the sample under investigation by suitable preliminary treatment, designed so that, as far as possible, the thiophene compounds and aromatic hydrocarbons remain unchanged in nature and amount. With this object a sample of the gas gasoline under examination was subjected to chemical purification: it was given two or three treatments with 78-79% sulfuric acid (10% by volume on amount of gasoline; 15 minutes; 2-3°), one or two treatments with 10% caustic soda (50% by volume on the amount of gasoline; 18-20°), and a chromatographic-adsorption treatment. These treatments resulted in the removal from the shale-gas gasoline of organic bases, partially unsaturated and readily polymerizable substances, and certain classes of oxygen- and sulfur-containing compounds, with the exception of thiophene and its homologs [1].

The chemical purification of shale oils rich in sulfur compounds first began to be discussed in the literature [2-4] in connection with the identification of the sulfur compounds present in shale oils and the development of a method of manufacturing ichthammol. Picon [1], who gives no experimental data, states that at below 30° 70% sulfuric acid has no action on thiophene and its homologs. We examined the behavior of thiophene and 2-methylthiophene, and of their solutions in benzene, toward 78-79% sulfuric acid, and we confirmed that no appreciable changes occur at 2-3° (Table 2).

There can be no doubt, however, that in such a treatment the thiophene compounds will to some extent be

* A later communication will deal with the composition of the thiophene-group component of the light fraction from the tar.

** In undertaking this work, the authors limited their task to the determination of the identities and contents of only those thiophene compounds that are present in more or less significant amounts in the products of the thermal treatment of Kashpir shales, including the gas gasoline.

removed mechanically by the acid, and that thiophenes may also be alkylated by olefins that are present and may react with aldehydes.

Fig. 1. Fractionation curve for purified gas gasoline before chromatographic treatment.

Fig. 2. Chromatogram of chemically purified gas gasoline.

Since, in our investigation, we were interested only in that part of the gas gasoline boiling below 200°, after purification and drying over calcium chloride the gas gasoline was generally distilled through a column at atmospheric pressure up to a temperature of 120°, and was then distilled up to the same temperature at a residual

pressure of 8-12 mm. Table 3 gives some of the characteristics of one of the chemically purified samples of gas gasoline.

We have shown that, when the object of investigation is the isolation of individual compounds from a gas gasoline or a shale-tar fraction and their quantitative estimation, chemical purification must be followed by chromatographic separation. The results on the individual composition of the thiophene fraction of shale tar published before this method of separation had acquired its present importance were obtained as the result of the treatment of large amounts of original material, and they are not always altogether convincing [2, 3]. When the chromatography stage is omitted and the shale-gas gasoline is fractionated through a column of 25-30 theoretical plates at a reflux ratio of 15-24, it is not possible to separate fractions boiling over narrow temperature ranges. Fig. 1 shows the fractionation curve for gas gasoline that has not been treated by chromatography. On this curve there is not a single clearly defined horizontal section, whereas there are several such sections on the fractionation curve (Fig. 3) for the same gasoline after chromatographic purification.

The difference in the distillation of gas gasoline before and after chromatographic treatment is to be explained by the fact that aromatic hydrocarbons and their thiophene analogs form azeotropic mixtures with certain saturated hydrocarbons [5]. This is confirmed by the group composition of chromatographed gas gasoline (concentrate of thiophenes and aromatics), which, as can be seen from Table 5, does not contain paraffins and cycloparaffins.

TABLE 4

B.p. of fraction (°C)	Gas gasoline after chemical purification			Gas gasoline after chemical purification and chromatography (thiophenes-aromatics concentrate)		
	Amount (%)	S (in %)	n_D^{20}	Amount (%)	S (in %)	n_D^{20}
Up to 78	4.8	3.04	1.4200	1.0	Nil	—
78-85	3.8	8.85	1.4670	5.7	8.9	1.4990

109-114	17.1	12.65	1.4800	31.2	15.8	1.5080
114-133	18.5	7.87	1.4515	Almost nil	—	—
133-138	12.2	11.78	1.4830	32.6	20.2	1.5072
138-156	10.3	6.52	1.4590	10.0	Not determined	—
156-163	4.5	9.15	1.4750	8.6	18.6	1.5080

The distribution of sulfur content among the various fractions is also to be explained by the formation of azeotropic mixtures. As will be seen from the analytical data given in Table 4, in the gas gasoline that was only chemically purified, sulfur-containing compounds are distributed over all of the fractions, whereas in the gas gasoline that was treated chromatographically on silica gel almost 80% of the thiophene compounds were concentrated in four fractions.

Hence, by the use of chromatographic adsorption on silica gel, gas gasoline can be completely freed from paraffins and cycloparaffins and can be partially freed from unsaturated hydrocarbons, as a result, losses of the thiophenes and aromatics due to the formation of azeotropic mixtures are avoided. Moreover, this method makes it possible to obtain a thiophenes-aromatics concentrate that is free from nonthiophene sulfur-containing compounds [6, 7]. In the chromatographic treatment of gas gasoline we followed the directions given in Soviet and foreign literature [8]. The chromatography* was carried out in a column provided with a cooling jacket, and the adsorbent was activated silica gel. For 50 ml of chemically purified gas gasoline or light tar fraction we took 150 g of silica gel. Ethanol (140-150 ml) was used as eluant. The eluate was collected in three or four parts, depending on the values found for the refractive indices; in the present investigation the important part of the eluate was that leaving the column at n_D^{20} = 1.4900-1.5120, since this contained mainly thiophenes and aromatic hydrocarbons. The yield of this part of the eluate, which we refer to as the thiophenes-aromatics concentrate, was 41-42% by volume with a sulfur content of 16-17%.

The chromatogram is given in Fig. 2, and some of the characteristics of the thiophenes-aromatics concentrate are given in Table 5.

* The chromatography was carried out with the collaboration of Ya. L. Danyushevsky. It will be described in a future communication.

Fig. 3. Fractionation curve for purified gas gasoline after chromatographic treatment.

Investigation of the thiophenes-aromatics concentrate was continued by fractionating it through a column of the usual type having an efficiency of 26-30 theoretical plates [9]. The fractions collected were 78-85°, 109-115°, 134-136°, and 156-163°, corresponding, respectively, to the boiling points of thiophene, methylthiophene, dimethylthiophene, and ethylmethylthiophene. The results of the fractionation are given in Table 6 and Fig. 3.

Apart from aromatic hydrocarbons and thiophene compounds, these fractions contained only unsaturated hydrocarbons (Table 6).

The closeness between the chemical properties of thiophene and its homologs and those of aromatic hydrocarbons, and also the possibility of the presence of different isomers of alkyl-substituted thiophenes, made the task of establishing the structure of individual compounds — even those contained in the narrow fractions characterized above — a very complicated one. For the solution of this problem we used both chemical and optical methods. The use of chemical methods of investigation was based on the ability of certain reagents to react preferentially with the thiophene components of the mixture. The selective reagents that we used were acetyl chloride in presence of stannic chloride [10], acetic anhydride in presence of iodine [11] or phosphoric acid [12], and mercuric acetate or chloride [13]. The resulting ketones and mercury derivatives of the thiophene series, being greatly different in physical and chemical properties from the accompanying aromatic hydrocarbons, can be almost quantitatively separated from the latter.

The derivatives of thiophene and its homologs, isolated from the corresponding fractions and then purified, were identified by comparison with compounds prepared synthetically from chemically pure thiophene and its homologs.

* The content of thiophenes in the separate fractions of the chromatographed gasoline was calculated from the analytical data for sulfur.

Isolation and Identification of Thiophene and Benzene

Methyl 2-Thienyl Ketone and Benzene. A mixture of 36.6 g of the 78-85° fraction, containing about 23.3% of thiophene, and 8.6 g of acetyl chloride was cooled to 0° and was stirred while 26.1 g of stannic chloride was added; stirring was then continued for one hour at room temperature. Water (50 ml) was added, the water layer was separated, and the organic layer was neutralized with 4% caustic soda solution. The reaction product was steam-distilled. In order to remove unsaturated compounds, the oily distillate was treated with 0.5% permanganate solution, and the excess of the oxidizing agent was reduced with sodium bisulfite in a weakly acid medium. The benzene layer was separated, washed with sodium carbonate solution and with water, diluted with ether, and dried with calcium chloride. In the distillation, two fractions were collected: b.p. 78-80° (atmospheric pressure), n_D^{20} 1.4996, yield 19 g (87.5%); and b.p. 86-87° (11 mm), n_D^{20} 1.5660 (the literature [14] gives n_D^{20} 1.5667), yield 10 g (80%). For identification of the benzene obtained from the 78-85° fraction, it was converted into m-dinitrobenzene, m.p. 89-90°, undepressed by admixture chemically pure m-dinitrobenzene.

Oxime of Methyl 2-Thienyl Ketone. A mixture of solutions of 4.6 g of the ketone (b.p. 86-87° (11 mm) isolated as above in 23 ml of alcohol, 5 g of hydroxylamine hydrochloride in 10 ml of water, and 4.1 g of caustic potash in 4 ml of water was heated in a water bath for three hours. When reaction was complete, the solution was cooled, and the precipitate present was filtered off and washed with a little alcohol. Water (30-40 ml) was added to the filtrate, and the oxime that precipitated on acidification with 10% sulfuric acid was filtered off, washed with water, and dried; yield 2.5 g. Two recrystallizations from alcohol gave 0.6 g of substance melting at 110-112°. For the oxime of methyl 2-thienyl ketone the literature [15] gives m.p. 112-113°.

Found %: C 51.79; 51.20; H 5.28; 5.00; S 22.70; 22.68

$C_4H_3SC(=N\cdot OH)\cdot CH_3$ Calculated %: C 51.06; H 4.96; S 22.70

A mixture of the substance with the oxime prepared from synthetic methyl 2-thienyl ketone melted at 110-112°.

Isolation and Identification of Toluene and 2-Methylthiophene

Methyl 5-Methyl-2-thienyl Ketone and Toluene. A mixture of 125.5 g of the 110-114.5° fraction, containing about 58% of methylthiophene, and 153 g of acetic anhydride was cooled with ice water and stirred while 14 g of orthophosphoric acid (sp. gr. 1.62) was added. The reaction mixture was then stirred at 100-110° for three hours. It should be noted that, when the temperature reaches 85°, spontaneous evolution of heat occurs and the temperature rises rapidly to 120°, so that it is necessary to cool the reaction mixture. When cool, the mixture was poured into 500 ml of ice water, neutralized with 10% sodium carbonate solution, and steam-distilled. The oily distillate was extracted with ether, dried with calcium chloride, and distilled, the following fractions being collected:

Fraction I, b.p. 100-110° (750 mm): n_D^{20} 1.4950; 33.2 g. After refractionation through a Widmer column: b.p. 109.5° (747 mm): n_D^{20} 1.4962; 25.4 g (50%).

Found %: C 91.53; 91.63; H 8.85; 8.82

$C_6H_5CH_3$ Calculated %: C 91.53; H 8.87

For the identification of the toluene isolated from the 110-114.5° fraction, it was converted into 2,4-dinitrotoluene, m.p. 68-69° (the literature [16] gives m.p. 70°). A mixture with synthetic 2,4-dinitrotoluene melted at 68-70°.

Fraction II, b.p. 84-91° (2-3 mm); n_D^{20} 1.5575; 73.6 g (88%). After refractionation: b.p. 104-105° (13 mm); n_D^{20} 1.5602. After freezing out (the melting point of the ketone is 27°) and distillation at 103-104° (10 mm) the value of n_D^{20} was 1.5610 (the literature [17] gives n_D^{20} 1.5620).

Found %: C 69.83; 69.95; H 5.92; 5.97; S 22.08; 22.98

$C_4H_2(CH_3)COCH_3$ Calculated %: C 69.00; H 5.71; S 22.85

Oxime of Methyl 5-Methyl-2-thienyl Ketone. From 30 g of the ketone, b.p. 84-91° (2 mm), 27 g of the oxime, m.p. 103-119°, was prepared by the method described above. After recrystallization from alcohol: m.p. 126-127° (the literature gives 124-125.5° [15], 128° [18]).

Found %: C 54.39; 54.40; H 5.73; 5.86; S 20.64

$C_6H_2S(CH_3)C(=N\cdot OH)CH_3$. Calculated %: C 54.19; H 5.81; S 20.64

A mixture with the oxime prepared from synthetic methyl 5-methyl-2-thienyl ketone melted at 128-127°.

Isolation of m-Xylene and 2,5-Dimethylthiophene

2,5-Dimethyl-3-thienyl Methyl Ketone and m-Xylene. A mixture of 60 g of the 134-138° fraction, containing about 70% of dimethylthiophene, and 29.4 g of acetyl chloride was cooled to 0° and stirred while dropwise addition was made of 97.6 g of stannic chloride, the temperature being maintained at about 0°. In order to complete the reaction, the mixture was stirred for a further two hours at room temperature. Water (100 ml) was added, and the xylene layer was separated, neutralized with a 4-5% caustic soda solution, and steam-distilled. The distillate was washed with sodium carbonate solution and with water, and was then extracted with ether. The ether extract was dried, ether was distilled off, and the residue was vacuum-distilled and gave the following fractions:

Fraction I, b.p. 33-105° (12-14 mm); n_D^{20} 1.5029. After redistillation through a column; b.p. 135-140.5 (736 mm); n_D^{20} 1.4992; yield 12.9 g. As sulfur was found in the xylene isolated, a second treatment with acetyl chloride and stannic chloride was necessary. From 2.7 g of the xylene, after suitable treatment and distillation at 751 mm, the following fractions were obtained: 1.1 g, b.p. 136-138°; 1.5 g, b.p. 138-141°, n_D^{20} 1.4963.

Analysis of xylene, b.p. 138-141°:

Found %: C 90.85; 90.69; H 9.34; 9.48

$C_6H_4(CH_3)_2$. Calculated %: C 90.56; H 9.44

According to Raman-spectrum analysis, which was carried out by M. L. Batuev, the main component of the product was m-xylene.

After two vacuum fractionations, Fraction II was collected: b.p. 103-104° (10-11 mm); n_D^{20} 1.5448; yield 40.6 g. For 2,5-dimethylthiophene, the value of n_D^{20} was found to be 1.5449 (the literature [19] gives 1.5452).

Oxime of 2,5-Dimethyl-3-thienyl Methyl Ketone. From 33 g of the ketone, b.p. 103-104° (10-11 mm), 31.9 g of the oxime was prepared by the method described above; after two crystallizations from alcohol it melted at 82-83° (the literature [19] gives 83° for the melting point of the oxime of 2,5-dimethyl-3-thienyl methyl ketone. A mixture of the oxime obtained (m.p. 82-83°) with the oxime of the ketone synthesized from 2,5-dimethylthiophene melted at 81.5-83°.

Found %: C 56.09; 56.51; H 6.47; 6.50; S 19.04; 18.95; N 8.28; 8.49

$C_4HS(:CH_2)_2C(NOH)CH_3$. Calculated %: C 56.70; H 6.50; S 18.92; N 8.29

Isolation and Identification of 2-Ethyl-5-methylthiophene

The question of the structures of thiophene compounds in the 156-163° fraction was complicated by the fact that this range corresponds to the boiling points of twelve isomers of composition $C_7H_{10}S$. Hence, limiting our task to the determination of the identity of the thiophene homolog forming the bulk of this fraction, we decided first to isolate it as a mercury derivative, and, having studied its composition, establish the number of side chains in this homolog. Since the fraction contained a certain amount of unsaturated hydrocarbons, which could react with mercury salts and so complicate our work, it was necessary to remove them from the fraction. With this object, a solution of 100 ml of the fraction (b.p. 156-163°) in 100 ml of ethanol was shaken with 1% potassium permanganate solution for 1-2 minutes at 10-15°. The excess of oxidizing agent was reduced with sodium bisulfite solution in an acid medium, and the upper layer was washed with 1% caustic soda solution and with water, and was then dried. Distillation gave 93.5 ml of a fraction boiling at 159-163° (763 mm) and containing 29.8% of sulfur.

Preparation of the Mercury Derivative from the Fraction of b.p. 159-163° (763 mm) [13]. Experiment 1.

Mercuric acetate (10 g) was dissolved in 400 ml of distilled water, and 2 ml of 67% acetic acid was added. The slight turbidity of the solution was removed by filtering it into a jar having a ground-in stopper, and 1.3 g of the fraction of b.p. 159-163° was added (1.3 g of the fraction contained about 1 g of alkylthiophenes of composition $C_7H_{10}S$). The mixture was shaken for four hours at room temperature (20-25°), and a white crystalline precipitate gradually formed. The mixture was set aside overnight at room temperature, and the heavy white precipitate was filtered off and washed, first with water and then with alcohol. The well pressed, still moist, finely crystalline

precipitate was removed from the filter, ground in a mortar with a little glacial acetic acid, filtered off, again washed with alcohol, and dried at 105-110°. The yield was 3.9 g.

Found %: Hg 62.84 (Adams' method [20])

$C_4S(CH_3)(C_2H_5)(HgOCOCH_3)_2$. Calculated %: Hg 62.36

Experiment 2. A filtered solution of 35 g of mercuric acetate in 870 ml of 69-70% acetic acid was stirred at 40-50° while 6 g of the 159-163° fraction (containing about 77% of compounds of formula $C_7H_{10}S$) was added. A white crystalline precipitate began to form after 6-7 minutes. The temperature was then raised to 60° and the mixture was stirred for three hours. On the next day the crystalline precipitate was filtered off, washed with warm water until the reaction was neutral, and then washed with alcohol. The yield was 19 g. Recrystallization of 5 g from 85 ml of glacial acetic acid gave 2.8 g of substance, which was dried at 105-110°. When heated rapidly in a capillary, the substance began to darken at 244-245° and melted with decomposition at 249-250°.

Found %: Hg 61.50; 62.30; C 20.35; 20.43; H 2.22; 2.34

$C_4S(CH_3)(C_2H_5)(HgOCOCH_3)_2$. Calculated %: Hg 62.36; C 20.52; H 2.19

Synthesis of 3,4-Bisacetoxymercuri-2-ethyl-5-methylthiophene from Synthetic 2-Ethyl-5-methylthiophene

2-Ethyl-5-methylthiophene. According to the literature [21], this thiophene homolog can be prepared in 40% yield by heating the semicarbazone of methyl 5-methyl-2-thienyl ketone with alkali. Using this method, we obtained only a 14% yield of 2-ethyl-5-methylthiophene (b.p. 158-160°; n_D^{22} 1.5073). We therefore decided to prepare it from the hydrazone of methyl 5-methyl-2-thienyl ketone [22]. A mixture of 35 g of methyl 5-methyl-2-thienyl ketone (n_D^{22} 1.5605), 200 ml of ethylene glycol (b.p. 195-197°), and 70 g of 85% hydrazine hydrate was prepared in a one-liter flask provided with a thermometer set with its bulb below the level of the liquid, a 24-cm fractionating column, and a condenser set for distillation. The reaction mixture was heated in an oil bath, the temperature being raised gradually over a period of 40 minutes to 160° (bath temperature 180°). Water and a little (about 1 g) of methyl 5-methyl-2-thienyl ketone distilled off. The liquid was cooled to 60°, 60 g of ground caustic potash was added, and heating was continued, the temperature being raised to 170°. At 130° vigorous evolution of nitrogen occurred and 2-ethyl-5-methylthiophene began to distil over. The ethylmethylthiophene was extracted with ether and the ether extract was washed — first with dilute (1:5) hydrochloric acid, then with sodium carbonate solution, and finally with water; it was dried with calcium chloride. The residue remaining after removal of ether was distilled at atmospheric pressure, and 26.3 g of a fraction of b.p. 158-159° (761 mm) was obtained. It had n_D^{22} 1.5073 (the literature [21, 22] gives n_D^{22} 1.5072).

3,4-Bisacetoxymercuri-2-ethyl-5-methylthiophene. Synthetic 2-ethyl-5-methylthiophene 2 g, b.p. 158-159° (761 mm), was added to a filtered solution of 5.1 g of mercuric acetate in 50 ml of 67% acetic acid. The resulting solution was shaken at 32-40° for two hours; a white crystalline precipitate began to appear after 10-15 minutes. On the next day the precipitate was filtered off and washed — first with 70% acetic acid, then with hot water, and finally with alcohol. The yield was 4.1 g (40%). Recrystallization from glacial acetic acid gave snow-white crystals (2 g) of the mercury derivative; they were filtered off and washed with glacial acetic acid and with alcohol.

Found %: Hg 62.43

$C_4S(CH_3)(C_2H_5)(HgOCOCH_3)_2$. Calculated %: Hg 62.36

Synthetic 3,4-bisacetoxymercuri-2-ethyl-5-methylthiophene, the same substance obtained from the 159-163° fraction, and a mixture of these two preparations were heated separately in capillaries at the rate of 9° per minute, and in each case the substance began to darken at 244-245°, and then melted with formation of glistening black specks at 249-250°. No further change occurred when the capillaries were heated to 280° in a sulfuric acid bath.

Identification of 2-Ethyl-5-methylthiophene in the Form of 3,4-Dibromo-2-ethyl-5-methylthiophene 1,1-Dioxide

Preparation of 3,4-Dibromo-2-ethyl-5-methylthiophene from Synthetic 2-Ethyl-5-methylthiophene. A solution of 36.7 g (11.7 ml) of bromine in 25 ml of carbon disulfide was added at room temperature over a period of 90 minutes to a solution of 12.6 g of 2-ethyl-5-methylthiophene in 20 ml of carbon disulfide. The solution was boiled for 10-15 minutes, and 3 g of cuprous cyanide was then added [23]. Carbon disulfide was removed at the pump, and the residue was boiled for 15 minutes with a solution of 4 g of caustic potash in 20 ml of alcohol. The reaction mixture was

diluted with water, acidified with hydrochloric acid, and steam-distilled. The product was 16.2 g (44.5%) of a faintly yellowish oil. It was dried and vacuum-distilled, when it gave 12.8 g of substance of b.p. 118-121° (7-8 mm) and n_D^{20} 1.5904. After being redistilled the substance had b.p. 119-121° (7-8 mm) and n_D^{20} 1.5898.

Found %: C 29.98; H 2.85

$C_4S(CH_3)(C_2H_5)Br_2$. Calculated %: C 29.60; H 2.82

3,4-Dibromo-2-ethyl-5-methylthiophene 1,1-Dioxide. 3,4-Dibromo-2-ethyl-5-methylthiophene (2.9 g) was dissolved in 26 ml of glacial acetic acid, and 4 ml of 30% hydrogen peroxide was added. The mixture was heated with stirring at 60-80° for 30 minutes and at 78-81° for five hours, after which it was poured in 200 ml of water. The reaction product was shaken twice with 75 ml of ether, the ether extract was dried with calcium chloride, and the ether was distilled off. The residual thick reddish-brown oil did not crystallize after being cooled and was allowed to stand for 36 hours. However, after the addition of 5-6 ml of dry methanol to the oil, a white crystalline precipitate of the dioxide began to form, and the amount of this increased appreciably when the mass was cooled to −1°. The dioxide was filtered off and washed with a little methanol (0.55 g of crystals, m.p. 55-56°).

The oil remaining after evaporation of the alcohol was again treated with 2 ml of hydrogen peroxide in glacial acetic acid at 60-75° for 12 hours, the further treatment being as described above. A further 0.70 g of the dioxide, m.p. 54-58°, was obtained, the total yield being 1.25 g (about 40%). After being recrystallized from methanol, the dioxide melted at 61-62°; further recrystallization did not affect the melting point.

Found %: C 26.70; 26.76; H 2.45; 2.42

$C_4SO_2(CH_3)(C_2H_5)Br_2$. Calculated %: C 26.59; H 2.55

Preparation of 3,4-Dibromo-2-ethyl-5-methylthiophene from the Fraction of b.p. 156-163°. The 156-163° fraction (42 ml) was first given a preliminary treatment with 2% potassium permanganate solution (two portions of 150 ml) in order to remove unsaturated hydrocarbons. Excess of oxidizing agent was reduced with sodium bisulfite in an acid medium, and the oil was then washed three times with water, twice with 1% caustic soda solution, and twice with water again. It was then dried with calcium chloride and distilled at 159-163°. The resulting fraction, amounting to 31.2 g, contained 17.6% of sulfur (equivalent to about 70% of 2-ethyl-5-methylthiophene). It was dissolved in 35 ml of carbon disulfide, and the solution was stirred for 75 minutes while a solution of 20 ml of bromine in 50 ml of carbon disulfide was added. Further treatment (see the experiment on the bromination of synthetic ethylmethylthiophene) gave 36.5 g of an oil. This was vacuum-fractionated, and the following three fractions were collected.

Fraction I, b.p. 45-100° (7-8 mm): 6.5 g; n_D^{20} 1.5025
Fraction II, b.p. 100-122° (7-8 mm); 7.4 g; n_D^{20} 1.5738
Fraction III, b.p. 122-124° (7-8 mm); 17.5 g; n_D^{20} 1.5880

Fractions II and III were combined and redistilled. The distillate collected (16 g) had b.p. 118-121° (7-8 mm) and n_D^{20} 1.5880.

Found %: C 30.08; 30.08; H 2.89; 2.83

$C_4S(CH_3)(C_2H_5)Br_2$. Calculated %: C 29.60; H 2.82

Preparation of 3,4-Dibromo-2-ethyl-5-methylthiophene 1,1-Dioxide from the Fraction of b.p. 159-163°. A solution of 2.9 g of the bibromo derivative (see preceding experiment) in 25 ml of acetic acid was warmed to 60° and was stirred while 6 ml of 30% hydrogen peroxide was added over a period of 26 hours, the temperature being raised gradually from 60° to 72°. The solution was then poured into 250 g of pounded ice, and a finely crystalline colorless substance was immediately precipitated together with a little oil. On the next day the mixture was cooled to 2-3° and filtered. The crystals were washed with water (1.65 g, m.p. 51-56°). Recrystallization from 8 ml of methanol gave 0.85 g of substance of m.p. 61-62.5°. In admixture with the synthetic dioxide it melted at 61-62.5°.

Found %: C 26.50; 26.31; H 2.47; 2.51

$C_4SO_2(CH_3)(C_2H_5)Br_2$. Calculated %: C 26.59; H 2.55

SUMMARY

It was shown that the main bulk of the light fraction of the thiophenes-aromatics part of Kashpir shale-gas gasoline consists of the following aromatic hydrocarbons and thiophene compounds: benzene, toluene, m-xylene, thiophene, 2-methylthiophene, 2,5-dimethylthiophene, and 2-ethyl-5-methylthiophene.

HIGH-TEMPERATURE REACTIONS OF DECANE OVER PLATINIZED ALUMINA IN PRESENCE OF HYDROGEN AT HIGH PRESSURE

Kh. M. Minachev, N. I. Shuikin, L. M. Feofanova, and Yu. P. Egorov

In a previous paper [1] we described an investigation of the contact-catalysis reactions of heptane in presence of platinum, palladium, rhodium, and ruthenium supported on silica gel at 460° and under 20 atm of hydrogen in a flow-type apparatus. A study of the catalysis products showed that, under these conditions, part of the heptane undergoes dehydrocyclization with formation of toluene:

and another part undergoes isomerization and hydrogenolysis into C_5-C_7 isoparaffins. It was found that the most active catalyst for the isomerization of heptane is platinized silica gel.

In the present investigation we have studied the reactions of decane in contact with platinized alumina at 460° under a hydrogen pressure of 30 or 50 atm in a flow system. Detailed investigation of the catalyzates showed that, under the given conditions, decane reacts in various directions. It was shown that the main products of these reactions are C_{10} isoparaffins, which are present in the catalyzate to the extent of 36-38% (depending on the pressure). The catalyzates were found to contain also isoparaffins of lower molecular weight, a small amount of aromatic hydrocarbons, and also some cyclopentanes and cyclohexanes.

The formation under these conditions of cyclopentanes and cyclohexanes is of particular interest. The presence of cyclopentane hydrocarbons in the catalyzates shows that they are formed not only at ordinary pressure over platinized charcoal of high platinum content (20%), as shown by Kazansky, Liberman, and coworkers [2, 3], but also under a pressure of hydrogen over platinized alumina containing only 1% of platinum. We consider that, within certain limits, the stabilizing effect of a pressure of hydrogen makes it easier to establish optimum conditions for the dehydrocyclization of alkanes with formation of cyclopentanes and to study the mechanism of this new reaction, for it is known [4] that increase in hydrogen pressure greatly reduces the tendency for the cyclopentane ring to open. Also, the results of the present work confirm that, as we have recently established [1], cyclohexane hydrocarbons are formed intermediately in the catalytic aromatization (dehydrocyclization) of alkanes.

Hence, the catalytic synthesis of cyclopentanes and cyclohexanes from alkanes occurs not only under the conditions of Zelinsky dehydrogenation catalysis, but also under considerably different conditions with respect to temperature, pressure, space velocity, and nature of catalyst.

EXPERIMENTAL

Synthesis of Decane. The Gringnard reaction between butyraldehyde and hexylmagnesium bromide yielded a secondary decanol, which was dehydrated over alumina at 320°. The dehydration product was suitably purified and then hydrogenated in the vapor phase at ordinary pressure in presence of platinized charcoal (1% Pt) at 210°. The resulting decane was treated with sulfuric acid, with sodium carbonate solution, and with water, and was distilled over sodium through a 36-plate column. The properties of the product were as follows: b.p. 173.5-174.5° (corrected); n_D^{20} 1.4120; d_4^{20} 0.7306; f.p. −29.5° to −30°; Found MR 48.45; Calculated MR for $C_{10}H_{22}$ 48.38. For decane the literature [5] gives the following properties: b.p. 174.11°; n_D^{20} 1.4118; d_4^{20} 0.7299; f.p. −29.67°.

Catalyst. The reactions studied were carried out in presence of platinized alumina (1% Pt), the preparation and properties of which we have described in a previous paper [6].

Experimental Conditions. The experiments were carried out at 460°. The decane was brought into contact with the catalyst at a space velocity of 1.1 hour^{-1}, the molar ratio of hydrogen to hydrocarbon being 5:1. Hydrogen pressures of 30 and 50 atm were used. The apparent volume of the catalyst was 50 ml. The apparatus and experimental arrangement were described in detail in a previous paper [1].

Investigation of the Catalyzates. Liquid catalyzates were characterized by density, refractive index, and content of aromatic hydrocarbons. The latter were separated from the naphthene-paraffin part of the catalyzate by chromatographic adsorption on silica gel [7]. The separation of n-alkanes from isoparaffins was effected by treatment of the mixture with urea. As cyclohexane was used as diluent in the treatment of the dearomatized part of the catalyzate with urea, hydrocarbons boiling up to 100° were first distilled from this part of the catalyzate through a 33-plate column. Hydrocarbons of the separate classes isolated in this way were identified by chemical and optical methods. Table 1 gives the properties of the catalyzates obtained by treatment of decane in presence of platinized alumina under the conditions stated above.

As will be seen from the data in Table 1, the properties of catalyzates obtained at different pressures do not differ essentially. However, when the pressure is raised from 30 to 50 atm, the content of aromatics in the catalyzate is appreciably reduced and the amount of saturated hydrocarbons in the gas is somewhat increased.

By adsorption on silica gel 4.6 g of aromatic hydrocarbons was separated from the decane catalyzate obtained at 30 atm. This fraction was distilled at 750 mm from a small flask provided with fractionating column; it had the following properties: b.p. 108-121° (the bulk came over at 108-114°), n_D^{20} 1.4955 and d_4^{20} 0.8630. Optical analysis of this fraction showed that it consisted of toluene together with a small amount of xylenes.

After the properties of the dearomatized part of the catalyzate has been determined, hydrocarbons boiling up to 100° were separated from it by distillation through a 33-plate column. The properties of these head fractions are given in Table 2.

The data given in Table 2 show that the properties of the hydrocarbons of the head fractions differ greatly, in spite of the closeness of the boiling limits. These fractions were subjected to optical analysis. Investigation of the first fraction, b.p. 52-100°, showed that it consisted of a mixture of cyclopentane hydrocarbons (mainly

methylcyclopentane) and isoparaffins. Judging from its aniline point, this fraction contained 55% of cycloalkanes (the calculated value was 55.8%). The fraction isolated from the catalyzate obtained at 50 atm consisted mainly of 2- and 3-methylhexanes.

Separation of n-Alkanes and Isoparaffins with the aid of Urea. As is well known, the method of separating n-alkanes from isoparaffins with the aid of urea has been very extensively used during recent years [8, 9]. We made use of this method for the separation of the n-alkanes in the dearomatized catalyzates from their isomers. Table 3 gives the properties of hydrocarbons of normal and branched structures after their separation by means of urea.

Spectrum Analysis of Products of the Catalytic Treatment of Decane. It is known that molecular-spectrum analysis of mixtures of complex hydrocarbons of the kerosene range (C_8 and higher) is rendered difficult by a lack of hydrocarbon standards and by the weakness of the Raman lines. Hence, the comparatively wide boiling range of the fractions separated by distillation and the probability of their containing various C_{10} isomers made it impossible to expect satisfactory results in their analysis by the Raman-spectrum method.

Infrared spectra of C_{11} paraffins.

In order to estimate the extent of branching in the hydrocarbons that we obtained, we made use of the relationships found by one of us on the basis of a new assignment of wave numbers in the CH vibration region [10]. When we compare the infrared absorption in this region (2800-2979 cm^{-1}) for C_{11} paraffins differing in extent of branching (number of CH_3 groups), we obtain the graphical relationship shown in the figure. In the case of paraffins containing a different number of carbon atoms, the changes in the peaks will be analogous. As the number of CH_3 groups is increased, the greatest changes are observed in the peaks at 3.51; 3.42, and 3.38 μ; with increase in ramification, the first two peaks become regularly lower, and the third becomes higher. The first two peaks are associated with the number of CH_2 groups, and the third with the CH_3 groups. When all of the spectra are obtained under identical conditions, then from the values of the ratios of the absorption coefficients for the 3.51 and 3.38 μ peaks and for the 3.42 and 3.38 μ peaks, we may form a fairly close idea of the extent of branching in the hydrocarbon or hydrocarbon mixture. For this purpose we selected the following conditions: spectrometer, Infrared-11; slit, 0.2 mm; concentration of hydrocarbon in carbon tetrachloride, 1:50 by volume. Control experiments on artificial binary and ternary mixtures gave satisfactory results (error about 10%).

Since the fractions isolated from the isoparaffin part of the decane catalyzate in experiments at 30 and 50 atm (see Tables 4 and 5) differed comparatively little in properties, the like fractions were combined for spectroscopic investigation. The following results were obtained. The Raman spectrum was determined for Fraction I, b.p. 100-130°, and we succeeded in showing the presence of isoparaffins (probably C_9) in admixture with methylcyclohexane. In order to obtain more precise information, 3.4 ml of this fraction was subjected to dehydrogenational catalysis at 300° over platinized charcoal. The resulting catalyzate had n_D^{20} 1.4160 (the original fraction had n_D^{20} 1.4105). This catalyzate was sulfonated, and the sulfonic acid obtained was decomposed by Kizhner's method, when 0.3 g was obtained of a substance which, according to its ultraviolet spectrum, contained toluene. This result is in accord with the indications obtained from Raman spectra.

Fraction II, b.p. 130-155°, was a mixture of C_9 and C_{10} isoparaffins in which mono- and di-substituted alkanes were present in almost equal amounts. Fraction III, b.p. 155-160°, consisted of about 40% of C_{10} mono- and 60% of C_{10} di-substituted alkanes. Fraction IV, b.p. 160-164°, contained about 70% of C_{10} mono- and 30% of C_{10} di-substituted alkanes. Fraction V, b.p. 164-167°, consisted of C_{10} monosubstituted alkanes. Fraction VI, b.p. 167-170° contained about 75% of C_{10} monosubstituted alkanes and 25% of unchanged n-decane.

Thus the combined method, applied to the investigation of the decane catalyzate, enabled us to establish the presence of cyclopentane and cyclohexane hydrocarbons in this catalyzate.

SUMMARY

1. An investigation was made of the contact-catalysis reactions of decane at 460° in presence of platinized alumina in a flow system, hydrogen being present at a pressure of 30 or 50 atm.

2. It was shown that, under the conditions described, this hydrocarbon undergoes some far-reaching transformations: the reaction product was found to contain aromatic hydrocarbons, cyclopentane and cyclohexane hydrocarbons, and C_7-C_{10} mono- and di-substituted alkanes. C_{10} monosubstituted alkanes formed 70% of the total amount of C_{10} isomers present.

CHEMICAL CHANGES PRODUCED IN THE CELLULOSE MACROMOLECULE BY OXIDIZING AGENTS

COMMUNICATION 9. OXIDATION OF CELLULOSE BY NITROGEN DIOXIDE

E. D. Kaverzneva, V. I. Ivanov, A. S. Salova, and S. A. Kist*

Shorygin and Khait [1] showed that, when cellulose is treated with gaseous nitrogen dioxide, practically no nitric ester groups are formed and the reaction product is completely soluble in hot sodium carbonate solution. According to their results, the action of oxides of nitrogen on cellulose differs markedly from that of other oxidizing agents, and makes it possible to introduce a large number of carboxyl groups into the fiber without affecting its appearance and strength. At the same time, the fiber acquires acidic properties and becomes readily soluble in alkalis. At first, therefore, this reaction was regarded as a specific oxidation of primary alcohol groups in the 6-positions of the glucose residues to COOH:

From 1942 onward the oxidation of cellulose by oxides of nitrogen was studied by Kenyon and coworkers, who published the first systematic work on this matter and patented this method of oxidation. They later investigated the quantitative determination of COOH groups in the resulting oxycelluloses [3], the solubility of the preparations in alkalis [4], and the possible mechanism of the reaction [5]. Their results were confirmed by Maurer and Reiff [6], who, by sufficiently prolonged oxidation, obtained preparations having COOH contents close to the value theoretically possible on the assumption that one alcohol group per glucose residue is oxidized (25.50%; theory requires 15.5%). Pfeiffer [7] investigated the effect of the conditions of oxidation and the properties of salts formed by the oxycelluloses with various metal cations. A result of these investigations was that the specificity originally assumed, almost unconditionally, for the oxidative action of nitrogen dioxide on carbohydrates (oxidation of only primary alcohol groups) began to be the subject of some doubt.

In his first papers, Kenyon explained some of the properties of celluloses oxidized by oxides of nitrogen, i.e. their high copper numbers and the readiness with which they are hydrolyzed in an alkaline medium, by the presence of a large number of electronegative COOH groups. This concept was clearly inadequate in view of the fact that alginic and pectic acids are completely stable to alkalis. Later, Kenyon, referring to our work [8], suggested that keto groups are formed in the course of the oxidation and that still other, not yet established, oxidative changes might occur. In recent work, Nevell [9] and Nabar and Padmanabhan [10] seek an explanation of the characteristic properties of these oxycelluloses in the supposed presence of various functional groups (keto, dialdehyde). According to Nevell's experiments, the amount of oxygen required in the formation of the oxidized preparations can be higher than two atoms per glucose residue, and the COOH content may exceed the theoretically possible value (he found 700 mmoles of COOH per 100 g of oxycellulose, instead of the calculated amount of 568 mmoles). Hence, in addition to the oxidation of primary alcohol groups, other oxidation reactions occur.

In spite of the considerable number of investigations that have been carried out, the mechanism of the oxidation of cellulose by oxides of nitrogen has not yet been studied and the identity of the chemical reactions occurring is far from clear. In most of the textbooks on wood and cellulose chemistry, e.g. "Wood Chemistry" (1952) by Hägglund, nitrogen dioxide is still classified as a specific oxidant.

* Deceased.

EXPERIMENTAL

The object of the present investigation was to obtain a more precise picture of the chemical changes undergone by cellulose when treated with oxides of nitrogen.

The experiments were carried out on purified bleached cotton cellulose taken in the form of gauze and cotton wool. Apparatus was set up for the preparation of nitrogen dioxide, its drying, and its distillation, and apparatus was set up also for carrying out the oxidation of the cellulose. The starting materials used for the preparation of nitrogen dioxide were nitric acid (sp-gr. 1.32-1.35) and technical ferrous sulfide. The oxidation of the resulting oxides was completed, and the product was dried over phosphoric oxide and distilled: b.p. 21.2-21.5°; yield 300-400 g from 1500 ml of nitric acid.

The oxidation of cellulose was carried out in a glass apparatus about 11 liters in volume; this was connected to a container for nitrogen oxides, which was provided with a reflux condenser. The excess gases were removed from the system through the condenser and an absorption vessel containing alkali. In most of the experiments some phosphoric oxide was introduced into the container for nitrogen oxides in order to bind the water formed, but complete removal of traces of water was not demanded by the experimental conditions, and the cellulose to be oxidized was taken in the air-dry condition.

Description of Experiments. The cellulose (50-100 g in the form of medicinal gauze or cotton wool) was placed in a large desiccator, which served as a reactor, and was supported by a glass stand or was wrapped on aluminum gauze. The necessary amount of nitrogen dioxide (generally 0.5-2.0 parts of NO_2 for each part of cellulose) was poured into a flask containing phosphoric oxide and connected by two tubes to the desiccator. A reflux condenser was attached to the flask. Oxidation was carried out at room temperature for 24-96 hours. When reaction was complete, the remaining oxides were displaced from the apparatus with dry air and the cellulose was transferred to cold distilled water. It was steeped in seven changes of water, and in the last, 60-minute steep the water acquired an acidity of not more than 0.003%, calculated as nitric acid. The oxycellulose was dried at not above 50°, since it yellowed at higher temperatures. The samples obtained were analyzed for moisture, ash, nitrogen, and functional groups, i.e. total [11] and uronic [12] carboxyls, aldehyde groups [13], and total carbonyl groups [14] by previously described methods, which have been partially modified by us [15]. In addition, carbonic ester groups [16], nitric ester nitrogen, and α-hydroxy ketone groupings were determined.

The methods that have been developed for the determination of functional groups in oxycelluloses required careful verification and considerable modification before they could be applied to oxycelluloses of the type under investigation. On account of the acidic properties of the the preparations, it was found to be essential to increase the acetate concentration in the determination of total carboxyls by the calcium acetate method so as to avoid excessive lowering of the pH of the solution. It was necessary also to increase the concentration of the borate buffer in the iodometric determination of aldehyde groups.

Qualitative Characterization of the Preparations Obtained. All of the preparations of cellulose oxidized with nitrogen dioxide were very acid, the pH of a water extract being 2.7-4.0. They gave positive reactions for lactone groups (with ferric chloride after condensation with hydroxylamine) and for enediol groups (Benedict's reagent). The reaction with potassium iodide for peroxide compounds was negative. The mechanical strength of the preparations was somewhat less than that of the original cellulose, and it fell appreciably as the samples were kept.

Functional Groups in Celluloses Oxidized with Nitrogen Dioxide

a) Nature of the Carboxyl Groups. As the analyses show, most of the carboxyls are uronic carboxyls and are therefore formed at C-6 (see Table 1).

TABLE 1

Nature of the Carboxyl Groups in Celluloses Oxidized with Nitrogen Dioxide

Experiment No.	Total COOH (%)	Uronic COOH (%)	Nonuronic COOH (%)	Uronic COOH / Total COOH (%)
8	10.90	8.95	1.95	82.1
6	12.08	9.4	2.68	77.8
7	12.53	11.09	1.44	88.5
9	14.80	11.65	3.15	78.7

Table 1 shows, however, that when the uronic COOH groups have been accounted for, there remain about 20% of the carboxyl groups that must occur in other positions in the glucose residues. The figures obtained have no absolute significance, but they reflect the fact that in oxycelluloses not all of the carboxyl groups are identical in their chemical properties. The value found for the nonuronic

carboxyl corresponds to 5-10 per 100 glucose residues. Such a number could be accommodated at the ends of macromolecular chains only if the degree of polymerization were very low – of the order of 20-10 – when the preparation would become brittle, lose its fibrous structure, and give solutions of negligible viscosity. The molecular weights of oxycelluloses prepared by the action of nitrogen dioxide cannot be measured by the existing methods. There is every reason to suppose, however, that these celluloses are of fairly high molecular weight. Cotton fibers, oxidized with nitrogen dioxide, lose part of their mechanical strength, but they differ little in appearance from unoxidized fibers; when dissolved in aqueous ammonia they give gels. According to our experiments, the viscosity of 0.5% solutions of the oxycelluloses in 0.2% caustic soda is at first high, but falls very rapidly (Figure 1).

All this indicates that the oxidized preparations have a fairly high degree of polymerization. In that case the number of nonuronic carbonyls found cannot be accomodated at the ends of chains, and it must be assumed that they are formed by the oxidation of secondary alcohol groups accompanied by scission of a C–C link in the pyran ring.

The work of Kenyon and coworkers [2] points to the reverse relation between total and uronic carboxyl groups, with the latter predominating. The cause of this is to be found in the fact that in the determination of COOH groups in Kenyon's experiments excessive lowering of the pH occurred owing to the presence of an inadequate amount of buffer; reaction was therefore not complete. Nevell [9] found values for the relative amounts of uronic and total COOH groups which were close to those found by us.

b) Aldehyde Groups in Celluloses Oxidized with Nitrogen Dioxide. Irrespective of the extent of oxidation, the content of aldehyde groups in preparations oxidized with nitrogen dioxide was very low (Table 2). Aldehyde groups were determined iodometrically. Oxidation with hypoiodite was carried out in a buffered medium having a pH of about 9 (0.1 M $Na_2B_4O_7$, 25°, 90 minutes). As we have shown [17], under these conditions α-hydroxy ketone groupings are not oxidized and therefore do not interfere in the determination.

Fig. 1. Fall in viscosity with time for solutions of oxycelluloses in 0.2% NaOH (temperature 20 ± 0.05°; measurements taken every 4-5 minutes after beginning of dissolution): 1) for 0.5% solution of Preparation 6; 2) for 0.4% solution of Preparation 6; 3) for 0.4% solution of Preparation 2.

TABLE 2

Content of Aldehyde Groups in Celluloses Oxidized with Nitrogen Dioxide

Experiment No.	Oxidation conditions	COOH groups (%)	Aldehyde groups (%)	Number of aldehyde groups per 100 glucose residues
16	70 hours 21-25°	11.45	0.04	0.24
6	48 hours 20-22°	12.08	0.05	0.30
15	72 hours 20-23°	14.0	0.02	0.12
9	92 hours 15-20°	14.8	0.06	0.35
L1	96 hours 16-20°	17.2	0.04	0.24
L11	96 hours 16-20°	16.8	0.07	0.42

It is impossible to exclude the possibility that some of the aldehyde groups exist in these celluloses in the combined state; having entered into the formation of acetal or acylal groupings. Acylal groupings are very sensitive to alkali and will react with iodine under the conditions for the determination of aldehyde groups; they behave, in fact, like free aldehyde groups. Acetal groupings are more stable and may not be determinable by the iodometric method. However, in the oxycelluloses studied in the present investigation there is a negligible number of free aldehyde groups – which, if present, would bring about a reduction in the stability of the cellulose and would be oxidized by hypochlorite, hydrogen peroxide, and other oxidizing agents. It must be pointed out, when NO_2-oxidized celluloses are kept, the number of aldehyde groups present rises very rapidly, so that the values given in the table can be obtained only as freshly oxidized preparations.

c) Keto Groups in Celluloses Oxidized with Nitrogen Dioxide. It was very important to establish whether there were any keto groups in the oxycelluloses; the presence of such groups has been considered on several occasions, but there was an inadequate basis for the resolution of this question. The difficulty lies in the fact that only the hydroxylamine method of Meesook and Purves [11] has been used in the quantitative determination of carbonyl groups in oxycelluloses, and this is inapplicable to celluloses oxidized with nitrogen dioxide because these oxycelluloses contain appreciable numbers of lactone groupings, which react with hydroxylamine [18] under the conditions required in the determination of carbonyl; the results are therefore too high. Moreover, the carboxyl groups of these oxycelluloses cannot be neutralized before the carbonyl determination without the dissolution of an appreciable part of the preparation. We attempted to break the lactone linkages by bringing the preparations gradually to pH 8.5 (treatment with alkali) and then determining carbonyl groups, but even a very short time in the alkaline medium resulted in the formation of new aldehyde groups. Decyclization of lactones by a one-hour treatment in hot 1% hydrochloric acid did not give better results: again there was some hydrolysis and the number of aldehyde groups increased. We therefore decided to apply the alcohol variant of the hydroxylamine method to the estimation of carbonyl groups in these oxycelluloses. In this method, which was developed by us [19], the determination is carried out at pH 4 with a solution of hydroxylamine hydrochloride in 90% alcohol: at this pH the lactone groupings do not take part in the reaction. As the acidity of the oxycelluloses was very high and it could not be suppressed completely by the use of an alcohol medium at pH 4, a correction was made in the titration results for the residual acidity of the oxycellulose. For this purpose, a separate, weighed sample of the oxycellulose was introduced into 90% alcohol and titrated in absence of hydroxylamine to pH 3.2 with 0.1 N NaOH.

The correctness of the carbonyl content, so determined, was checked by determining the nitrogen content of the oxycellylose oxime, prepared, as indicated, in an acid alcoholic medium and then washed with alcohol. The nitrogen content, after subtraction of the component attributable to nitric ester groups, was 91-95% of the value calculated from the carbonyl content found by titration (Table 3).

TABLE 3

Verification of the Method of Determining Carbonyl Groups by Comparison with Nitrogen Determinations on Preparations Condensed with Hydroxylamine Hydrochloride

Experiment No.	N content before condensation with $NH_2OH \cdot HCl$ (%)	N content after condensation with $NH_2OH \cdot HCl$ (%)	Increase in N content due to condensation (mg-equiv. per 100 g)	Carbonyl content found by titration (mg-equiv. per 100 g)	$\frac{N}{CO}$ (%)
30	0.16	1.51	96	105	91.8
32	0.18	1.75	112	123	91.0
1-c	0.18	1.75	112	117	95.7

The oxidized glucose residues contain single keto groups and also, probably, diketone groupings. The presence of α-hydroxy ketone groupings was confirmed by the endiol reaction with a phosphoric-arsenic-tungstic reagent (Benedict's), which we have developed for celluloses [17]. In this reaction, all of the celluloses oxidized with nitrogen dioxide gave a dark-blue coloration, which indicates high contents of hydroxy ketone groupings. Tentative quantitative determinations of hydroxy ketone groupings with the aid of this reaction gave much higher values for NO_2-oxidized celluloses than for oxycelluloses of other types.

Table 4 gives the total carbonyl content and the contents of aldehyde, ketone, and hydroxy ketone groupings in oxycelluloses obtained by oxidation with oxides of nitrogen.

TABLE 4

TABLE 5

Content of α-Hydroxy Ketone Groupings at various Stages of the Oxidation of Cellulose

Preparation No.	Number of groupings per 100 glucose residues			Hydroxy ketone / Total ketone (%)	Mol. wt. of structural unit
	COOH	Total ketone	Hydroxy ketone		
28	7.0	0.64	0.55	86	163.1
30	44.3	16.36	3.74	23	168.6
19	53.9	18.80	3.65	19	170.0
32	65.8	18.72	3.56	24	172.0

For the determination of α-hydroxy ketone groupings, a 0.1-g or 0.05-g sample of oxycellulose was covered with 1 ml of 10% sodium carbonate in a large test tube and heated in a water bath at 80° for 20 minutes. The mixture was cooled, 0.5 ml of Benedict's reagent was added, and, after 15 minutes, the volume was made up to 30 ml with water. The solution was passed through a glass filter, and the intensity of the color was measured on a photometer with an M-57 yellow-green filter (574 mμ). The content of hydroxy ketone groupings was calculated from a calibration curve obtained for ascorbic acid, the reaction being carried out under the same conditions, but without the treatment with hot sodium carbonate solution. On a percentage basis, at the beginning of the oxidation α-hydroxy ketone groupings predominated, whereas in the later stages other, probably diketone groupings, predominated (Table 5).

d) Carbonic Ester Groupings. Glucose residues in the cellulose chain that have been oxidized with opening of the ring and formation of carbonic ester groupings  should be particularly sensitive to the action of an alkaline medium. Analyses for these groupings (Table 6) by the method that we have developed [16] showed that in nitrogen dioxide oxidation practically no such groupings are formed, for the preparations do not yield carbon dioxide when treated with 1% caustic soda in the cold.

27	2.50	0.018	0.071
22	6.35	0.077	0.30
26	13.30	0.081	0.32

TABLE 7

Forms of Nitrogen in Celluloses Oxidized with Nitrogen Dioxide

Preparation No.	COOH groups (%)	Nitrogen		
		Total (%)	as nitric ester (%)	Difference
28	12.93	0.72	0.71	0
27	2.53	1.26	1.03	+ 0.23
22	6.35	2.54	2.33	+ 0.21
26	13.3	0.21	0.11	+ 0.10

The traces of carbon dioxide obtained from strongly oxidized preparations were probably formed by the decarboxylation of rather unstable oxidation products, and they cannot be regarded as proof of the presence of carbonic esters.

e) Form in which Nitrogen Occurs in Celluloses Oxidized with Nitrogen Dioxide. After being oxidized with nitrogen dioxide, celluloses always contain some nitrogen, the amount of which varies greatly according to the oxidation conditions. In the course of the oxidation, the nitrogen content rises at first, and then, after some time, begins to fall, as indicated in Fig. 2. The total nitrogen was determined by the Kjeldahl method, the preparation being first reduced with zinc and salicylic acid. Also, nitric ester nitrogen was determined by the Schultz-Tiemann method [20] (reduction with ferrous chloride and volumetric determination of the nitric oxide evolved). The two methods gave closely agreeing results, which indicates that all of the nitrogen present in these oxycelluloses is in the form of ester groupings (Table 7).

Fig. 2. Variation of nitrogen and carboxyl contents of cellulose with extent of oxidation.

Fig. 3. Carbonyl content as a function of the extent of oxidation of cellulose: 1) keto groups; 2) α-hydroxy ketone groupings; 3) aldehyde groups.

Discussion of Experimental Results

According to the oxidation mechanism proposed by Kenyon and coworkers, the oxidation of cellulose with nitrogen dioxide begins with the esterification of primary OH groups by the traces of nitric acid present. The second stage of the reaction consists in the oxidative denitration of the nitric ester groupings by the action of N_2O_4 in presence of HNO_3. The presence of nitrogen in the oxycelluloses is explained by these authors by the esterification of a few secondary hydroxyls, with the formation of ester groupings that are not subsequently hydrolyzed. Our experiments on the oxidation of cellulose, and also of simple hydroxy compounds [21], are in accord with the intermediate formation of nitric ester groupings in the oxidation. This view, however, must be extended, since not only primary, but also secondary OH groups take part in the reaction. Our investigations show that, in the reaction between nitrogen dioxide and isopropyl alcohol, intermediate formation of a nitric ester occurs; hydrolysis of this yields acetone. Analogous reactions were established for the primary and secondary OH groups in various compounds (ethylene glycol, 1,2-propanediol, methyl glucoside).

The formation of keto groups in oxycelluloses proves that in polysaccharides OH groups can react by this mechanism, i.e. after the formation of a nitric ester, under certain conditions the ester grouping may be eliminated with simultaneous oxidation.

Our work has shown that the oxidation of cellulose with nitrogen dioxide is not specific, for it brings about oxidative changes in different directions. These changes, however, are sufficiently characteristic to give us grounds for placing this oxidizing agent in a special group. Both primary and secondary alcohol groups are oxidized with formation, respectively, of carboxyl groups at C-6 and keton groups at C-2 or C-3. The oxidation of primary alcohol groups proceeds to a very much greater extent than that of secondary alcohol groups, which is in accord with the idea of the formation of nitric esters in the first stage of the reaction. Further oxidation occurs at the keto groups with opening of the ring, but the extent to which this occurs is only slight. Aldehyde groups are essentially absent, and the aldehyde content can be neglected. The content of keto groups rises as the carboxyl content rises, and it may attain more than 18 per 100 glucose residues (Fig. 3).

Judging from the strong endiol reaction, a considerable proportion of the keto groups are present in the form of α-hydroxy ketones, the amount of which corresponds closely to the total keto group content at the beginning of the

reaction, but falls, when expressed as a percentage of the total number of keto groups, as the reaction proceeds.

Some authors have remarked on the great similarity in properties between the oxycelluloses obtained by nitrogen dioxide oxidation and those obtained by periodic acid oxidation – there is the instability of both types of oxycelluloses in an alkaline medium [10], the formation of new carboxyl groups when the preparation stands in an alkaline medium, the insolubility of the nitric esters [22], etc. – and they have tended to explain this resemblance by the presence of dialdehyde groupings in NO_2-treated cellulose. Direct determination shows that there are very few aldehyde groups in these oxycelluloses. Moreover, the hydroxy ketone groupings, which are present in large numbers, are very similar to dialdehyde groupings in their effect on the properties of the oxycelluloses: they also bring about a great reduction in stability to alkali, being converted by alkali into endiols, and then further into carboxyl groups by oxidative scission of the ring. There is therefore no need to postulate the presence of dialdehyde groupings in oxycelluloses obtained by nitrogen dioxide oxidation. Also, the formation of these groups is difficult to reconcile with the proposed oxidation mechanism through the intermediate stage of nitric esters and also with the great ease with which aldehyde groups are oxidized by nitrogen dioxide.

On the other hand, it is quite probable that, when there are high contents of both carboxyl and keto groups in cellulose preparations obtained by nitrogen dioxide oxidation, glucose residues occur which contain both of these groups simultaneously. This accumulation of functional groups in one structual unit must result in a further reduction in the stability of such units and in the ready breakdown of the macromolecule. The probability of the presence of such highly oxidized units has been recently confirmed by the isolation of 3,5-dihydroxy-4H-pyran-4-one from the hydrolyzate of an oxycellulose [23].

SUMMARY

1. The oxidation of cellulose by nitrogen dioxide does not consist in the specific oxidation of primary alcohol groups, this reaction being always accompanied by the oxidation of secondary alcohol groups.

2. In celluloses oxidized with nitrogen dioxide, most of the carboxyl groups formed are in the 6-positions of the glucose residues. Some of the carboxyl groups are formed as a result of oxidative scission of the pyran ring.

3. Celluloses oxidized with nitrogen dioxide contain many carbonyl groups (as many as 19 groups per 100 glucose residues, the number of carboxyl groups then being 65). In freshly oxidized preparations most of the carbonyls are keto groups, and the content of aldehyde groups is low (not more than 0.3 per 100 glucose residues).

4. Celluloses oxidized with nitrogen dioxide do not contain peroxy and carbonic ester groupings. All of the nitrogen in these oxycelluloses is present in the form of nitric ester groupings.

5. The experimental material obtained supports the suggestion that oxidation proceeds with intermediate formation of nitric esters. It is necessary to assume that ester formation and the oxidative hydrolysis of the product can occur not only at primary OH groups, but also at secondary OH groups in the glucose residues of the cellulose macromolecule.

FORMATION OF LOW-MOLECULAR-WEIGHT POLYMERS OF VINYL ETHERS IN PRESENCE OF BENZOYL PEROXIDE

M. F. Shostakovsky, E. S. Shapiro, and F. P. Sidelkovskaya

As is well known, benzoyl peroxide is very extensively used as an initiator of the polymerization of unsaturated compounds. Many investigations have been carried out on the decomposition of benzoyl peroxide in various media. One of us and coworkers [1] studied the reaction of butyl and phenyl vinyl ethers with substantial amounts of benzoyl peroxide (10-50% by weight), and it was shown that, under the conditions employed, benzoyl peroxide mainly plays the part of an adding agent reacting at the double bond of the vinyl ether. The clear viscous products obtained in this reaction had an acylal structure $C_6H_5COOCH_2CH\langle^{OR}_{OCOC_6H_5}$. It was found also that reduction in the amount of peroxide taken for reaction resulted in the formation of products having higher molecular weights than that of the addition product.

It was considered to be of interest to study the interaction between vinyl ethers and catalytic amounts of benzoyl peroxide. It was important to establish whether a polymerization reaction occurred under these conditions, for it has been shown quite recently that it is possible in principal to bring about the polymerization of vinyl ethers under the influence of other free-radical initiators [2-4].

In the present investigation we used isopropyl and butyl vinyl ethers at two different temperatures. The experiments were carried out in sealed tubes for different periods of time, the benzoyl peroxide concentrations being 10, 5, 2.5, and 1% by weight for the first ether and 1, 0.5, 0.2, and 0.1% by weight for the second. It was shown that some undecomposed benzoyl peroxide still remained after five hours when butyl vinyl ether was heated with 1% of benzoyl peroxide at 60°; after ten hours the whole of the peroxide had decomposed and the yield of viscous reaction product had increased appreciably. Experiments were carried out in which the tubes were sealed off a) in the atmosphere and b) at a residual pressure of 1-2 mm. However, no difference was found in yield of product or in rate of decomposition of benzoyl peroxide, and in subsequent experiments the tubes were always sealed off in the air. A period of heating of 120-140 hours was found to be sufficient for the obtaining of reproducible results in different parallel experiments, both with respect to total yield and with respect to the constants of the polymeric product. Control experiments showed that no thermal polymerization of the vinyl ether was to be observed under these conditions of prolonged heating.

Interaction between butyl vinyl ether and benzoyl peroxide under the above-described conditions resulted in the formation of colorless polymeric products in very low yield (1-5% on the amount of the ether taken for reaction). These products are completely stable to storage: they do not eliminate benzoic acid, as the acylal addition products do. In this respect they differ greatly from the products obtained by heating isopropyl vinyl ether with 5-10% of benzoyl peroxide: these also gradually eliminate benzoic acid. The polymeric products are soluble in all organic solvents, but most readily in ether.

The results of experiments carried out at 60° and 80° are given in Tables, 1, 2, and 3, from which it will be seen that, under the given conditions, the following regular behavior is observed: with reduction in the benzoyl peroxide concentration the yield (on the amount of peroxide taken) and molecular weight of the polymeric product increase and its refractive index and density diminish. The temperature dependence of the reaction must be emphasized. At a given benzoyl peroxide concentration (0.5, 0.2, or 0.1%) the yield and molecular weight of the polymeric product are considerably higher at 80°. The change in the constants of the polymeric products is still more marked, and the products become closer in elementary analysis to poly[butyl vinyl ether] (Table 4). On the other hand, the constants and analytical results for the products obtained with 10% and 5% of benzoyl peroxide differ greatly from those for poly[isopropyl vinyl ether] (Tables 3 and 5). This is in complete accord with the fact that these products are closer to acylals in their properties.

Hence, interaction between an alkyl vinyl ether and benzoyl peroxide taken in a concentration of less than 1% results in the polymerization of the ether to polymers of low molecular weight. The process can probably be

represented as follows: the benzoate radicals formed by the decomposition of benzoyl peroxide react at the double bond of the alkyl vinyl ether and initiate polymerization, but the resulting chain reaction is slow and gives short polymer chains $C_6H_5COO-(CH_2-\underset{\underset{OR}{|}}{CH})_n\ldots$ In this connection it is of interest to compare the results for the polymerization of some vinyl ethers in presence of another radical initiator, e.g. 2,2'-azobis[2-methylpropionitrile].

For butyl vinyl ether in presence of the azo nitrile, the yield of polymer ranges from 9% to 25% (on the amount of the ether taken), depending on the amount of initiator used. Similar yields of polymer are obtained from isopropyl and cyclohexyl vinyl ethers in presence of the azo nitrile [4]. Phenyl vinyl ether does not polymerize so readily in presence of the same initiator [3], the yields of polymeric products of molecular weight 700–800 being 7–14% on the amount of the ether taken.

TABLE 6

Heating of Butyl Vinyl Ether with Benzoyl Peroxide at 60°

Experiment No.	Amount taken		Method of sealing tube	Duration of heating (hours)	Peroxide remaining undecomposed (%)	Yield of reaction product (%)	Constants		
	Butyl vinyl ether	Benzoyl peroxide (% by weight)					n_D^{20}	d_4^{20}	M
1	49.4	0.5	In the air	5	8.4	1	1.5049	—	—
2	49.8	0.5	In a vacuum	5	9.7	1	1.5040	—	—
5	75	0.75	In the air	10	None	1.93	1.4946	1.0312	399.4; 409.1
6	90	0.5	In the air	10	None	1.22	1.4880	Not determined	537.7; 523

It follows from this comparison that, in polymerizing in presence of free-radical initiators, vinyl ethers give polymers of comparatively low molecular weight in low yield.

In our case, the part played by benzoyl peroxide in the polymerization of vinyl ethers is even more limited, mainly owing to the fact that at the peroxide concentrations of more than 2% the action of the benzoyl peroxide as an adding agent – reacting at the double bond of the vinyl ether – begins to become effective. This action results in the inhibition of the polymerization reaction.

EXPERIMENTAL

Procedure. Weighed amounts of alkyl vinyl ether and benzoyl peroxide were introduced into a glass tube. When low concentrations were used (of the order of 0.1 or 0.2%), the solutions were prepared separately and then poured into the tubes. The tubes were sealed off either in the air or in a vacuum (residual pressure 1-2 mm). The tubes were placed in a thermostat at 60° or 80°, and were kept there for the required time. The tubes were then cooled, and their contents were transferred to a distillation apparatus. The alkyl vinyl ether was distilled off at 5 mm at room temperature in a current of nitrogen, and it was collected in a coiled receiver cooled to a temperature of −70 to −75°. The polymeric residue was brought to constant weight by exposing it to a vacuum (2-3 mm) at 60° (generally for 15-18 hours). The results of all of the experiments are given in Tables 1, 2, and 3. The results of some experiments that were not carried out under standard conditions are given in Table 6.

Control Experiments. a) At 60°. A tube containing 90.1 g of butyl vinyl ether was sealed in the air. After being heated under the above-described conditions for 120 hours, the contents were distilled and gave 89 g of butyl vinyl ether. The residue amounted to 0.08 g, or 0.09% on the weight of the ether taken for reaction.

b) At 80°. Butyl vinyl ether (90 g) was heated in a sealed tube for 140 hours. After the usual treatment of the contents, the residue amounted to 0.1 g, or 0.11% on the weight of the ether taken for reaction. Hence, under the given conditions practically no thermal polymerization occurs.

SUMMARY

1. The interaction of butyl and isopropyl vinyl ethers with benzoyl peroxide was studied at peroxide concentrations of 0.1-10%.

2. It was shown that, at benzoyl peroxide concentrations of 2% and less, the vinyl ether polymerizes with formation of products of low molecular weight. At peroxide concentrations of 5% and 10%, addition and polymerization reactions occur simultaneously.

BRIEF COMMUNICATIONS

PREPARATION OF HEXAALKOXYDITITANOXANES $(RO)_3Ti-O-Ti(OR)_3$

A. N. Nesmeyanov, O. V. Nogina, and R. Kh. Freidlina

In a previous paper [1] we described the preparation of trialkoxytitaniums, and we also described briefly the reaction occurring when tripropoxy- and tributoxy-titaniums are oxidized by air. Compounds of composition $(C_3H_7O)_2TiO$ and $(C_4H_9O)_2TiO$ were isolated from the reaction mixture. These dialkoxytitanium oxides are solids that are readily soluble in all inert organic solvents. We did not succeed in crystallizing them. A more detailed study of the oxidation of trialkoxytitaniums has shown that, depending on the reaction conditions, not only dialkoxytitanium oxides, but also hexaalkoxydititanoxanes are formed.

When triethoxytitanium was oxidized, the main product was hexaethoxydititanoxane. By repeated recrystallization of the mixture of solid reaction products, hexaethoxydititanoxane was finally isolated in the pure state. This compound has not been described in the literature.

As two authors of this paper have shown in collaboration with r ainina [2], hexaethoxydititanoxane cannot be prepared by the hydrolysis of tetraethyl orthotitanate; when tetraethyl orthotitanate reacts with water at a molar ratio of 2:1, the product is not hexaethoxydititanoxane, formed in accordance with the equation

$$2(C_2H_5O)_4Ti + H_2O \rightarrow (C_2H_5O)_6Ti_2O + 2C_2H_5OH,$$

but octaethoxytrititanoxane $(C_2H_5O)_8Ti_3O_2$.

Bradley, Gaze, and Wardlaw [3] have recently reported that in the reaction between tetraethyl orthotitanate and water at a molar ratio of 2:1 they obtained not hexaethoxydititanoxane, but a substance containing 66.3-67.8% of ethoxyl groups and 25.7-26.1% of titanium. The authors did not succeed in establishing the structure of this compound. It is clear that they obtained the octaethoxytrititanoxane already described [2] (calculated ethoxyl content 67.1%, titanium content 26.81%).

Until now, there has been no method available for the synthesis of hexaalkoxydititanoxanes. There are reports of the formation of hexabutoxydititanoxane [4] and hexaallyloxydititanoxane [5] in the thermal decomposition of the corresponding tetraalkyl orthotitanates. In these investigations, however, the reaction products were analyzed without a preliminary purification, and then only for titanium content; the values found differed greatly from the calculated values. There is also a report that hexabutoxydititanoxane was obtained in the hydrolysis of tetrabutyl orthotitanate [6], but again the analysis, which was only for titanium, was carried out on the unpurified product. It should be noted that in all of these cases hexaalkoxydititanoxanes were described as viscous liquids or semisolids. The hexaethoxydititanoxane that we have prepared by the oxidation of triethoxytitanium was obtained as a white crystalline substance after crystallization from a mixture of alcohol and petroleum ether; it was readily soluble in alcohol and benzene, but less readily soluble in petroleum ether.

Hexapropoxy- and hexabutoxy-dititanoxanes were prepared by the transesterification of hexaethoxydititanoxane with propyl and butyl alcohols. We succeeded in crystallizing these substances from a mixture of the corresponding alcohol and petroleum ether. The hexaalkoxydititanoxanes obtained were exceptionally hygroscopic and were very readily hydrolyzed. Cryoscopic determination of the molecular weight of hexaethoxydititanoxane in benzene showed that the substance associates in solution, and only at high dilution did the molecular weight found approximate to that calculated for the nonassociated compound.

EXPERIMENTAL

Preparation of Hexaethoxydititanoxane $(C_2H_5O)_6Ti_2O$

a) Preparation of Triethoxytitanium $(C_2H_5O)_3Ti$. Potassium (8 g) was introduced into a three-necked flask filled with nitrogen and fitted with reflux condenser and mercury-sealed stirrer. A solution of 24 g of tetraethyl

orthotitanate in 200 ml of absolute ethanol was then poured into the flask, and there was an immediate dark-brown coloration. When the whole of the potassium had reacted, the reaction mixture was transferred, by the aid of nitrogen under pressure, to a funnel with a No. 3 glass filter. The air contained in the cylindrical funnel was first carefully displaced by dry nitrogen. The precipitate was filtered off under suction and washed three or four times with absolute ethanol to remove potassium ethoxide and then twice with petroleum ether at 30-50°. The reaction product was then dried under reduced pressure (2-3 mm) in a current of dry nitrogen at room temperature for 10-15 minutes. The product so obtained can be used for the oxidation. The carefully dried substance (dried for about one hour under the conditions indicated) is of a reddish-lilac color. It is sparingly soluble in the usual organic solvents, and it is extremely sensitive to oxygen and to atmospheric moisture. In its properties it is very close to the previously described [1] tripropoxy- and tributoxy-titanium.

b) Preparation of Hexaethoxydititanoxane. The dry triethoxytitanium prepared as described above was oxidized directly on the funnel by means of a current of dry oxygen. The oxidation products gradually flowed into the receiver in the form of a viscous liquid. The oxidation of the triethoxytitanium obtained by the reduction of 24 g of tetraethyl orthotitanate was complete in 2.5-3 hours. The liquid reaction products were evaporated at 30-40° under reduced pressure (25-40 mm). The residue was recrystallized three times from a 1:1 mixture of ethanol and petroleum ether (50-70°). The yield was 2 g; m.p. 132-134°.

	Found %:	C 37.81; 37.70;	H 7.68; 7.87;	Ti 25.02; 25.11
$C_{12}H_{30}O_7Ti_2$.	Calculated %:	C 37.71;	H 7.91;	Ti 25.07

Found: M* 397.7
Calculated: M 381.8

Preparation of Hexapropoxydititanoxane ($(C_3H_7O)_6Ti_2O$)

Hexaethoxydititanoxane (0.9 g) was dissolved by warming it with 2 ml of propyl alcohol, and the solution was heated under conditions that permitted the removal of alcohols by distillation, the bath temperature being raised very slowly. At a vapor temperature of 77-80°, 0.67 g of liquid – mainly ethanol – came over (calculated amount 0.65 g). A further 2 ml of propyl alcohol was then added, and the distillation operation was repeated. The residue remaining after the distillation of the excess of propyl alcohol was recrystallized from a 1:1 mixture of propyl alcohol and petroleum ether.

	Found %:	C 46.52; 46.61;	H 9.08; 9.2½;	Ti 20.16; 20.41
$C_{18}H_{42}O_7Ti_2$.	Calculated %:	C 46.36;	H 9.08;	Ti 20.54

Preparation of Hexabutoxydititanoxane ($(C_4H_9O)_6Ti_2O$)

Hexaethoxydititanoxane (1.1 g) was dissolved by heating it with 5 ml of butyl alcohol. The mixture of alcohols was distilled off at 35 mm from a bath at 50-55°. The reaction mixture was then cooled, and a further 5 ml of butyl alcohol was added. The mixture of alcohols was distilled off at 35 mm from a bath at 65-70°. The last operation was repeated. The residue remaining in the flask after the distillation of the excess of butyl alcohol the last traces of which were removed under reduced pressure (2 mm) at 50-60°, was analyzed.

	Found %:	C 52.67; 52.43;	H 9.83; 9.80;	Ti 16.89; 16.88
$C_{24}H_{54}O_7Ti_2$.	Calculated %:	C 52.36;	H 9.88;	Ti 17.40

In another experiment the transesterification treatment was applied to some hexaethoxydititanoxane which analysis showed to be of inadequate purity, and the hexabutoxydititanoxane obtained was purified by two recrystallizations from a 3:1 mixture of petroleum ether and butyl alcohol.

	Found %:	C 52.32; 52.36;	H 9.74; 9.73;	Ti 17.22; 17.27
$C_{24}H_{54}O_7Ti_2$.	Calculated %:	C 52.36;	H 9.89;	Ti 17.40

Hexabutoxydititanoxane is readily soluble in alcohols and benzene, but not so readily soluble in petroleum ether.

SUMMARY

1. Hexaethoxydititanoxane was prepared by the oxidation of triethoxytitanium.

* The value of the molecular weight obtained for these substances varied from one determination to another. Thus, for another sample, of about the same weight, the molecular weight was found to be 500.

2. Hexapropoxy- and hexabutoxy-dititanoxanes were prepared by the transesterification of hexaethoxy-dititanoxane.

ORGANOBORON COMPOUNDS

COMMUNICATION 6. ACTION OF PHOSPHORUS PENTACHLORIDE ON DIARYLBORINIC ESTERS. SYNTHESIS OF DIARYLCHLOROBORINES

B. M. Mikhailov and N. S. Fedotov

We have found that phosphorus pentachloride reacts with propyl diphenylborinate with formation of chlorodiphenylborine (diphenylborinic chloride) in high yield, together with propyl chloride and phosphoryl chloride in accordance with the equation:

$$(C_6H_5)_2BOC_3H_7 + PCl_5 = (C_6H_5)_2BCl + POCl_3 + C_3H_7Cl.$$

Phosphorus pentachloride reacts similarly with isobutyl di-1-naphthylborinate with formation of chlorodi-1-naphthylborine in 70% yield.

Diarylborinic chlorides have previously not been readily accessible owing to the absence of a convenient method of preparation. The only organoboron compound of this type that has been prepared — chlorodiphenylborine — was obtained in low yield by heating diphenylmercury with dichlorophenylborine at 320° for one day [1].

The method that we have found makes diarylborinic chlorides accessible and opens up wide possibilities for their use in synthesis.

EXPERIMENTAL

Chlorodiphenylborine. Phosphorus pentachloride (18.6 g) was added with shaking to 20 g of propyl diphenylborinate [2] b.p. 142-143° (5 mm) contained in a flask fitted with a Vigreux column. Reaction occurred with evolution of heat. When reaction was complete, propyl chloride and phosphoryl chloride were removed under reduced pressure (the coiled receiver being cooled with solid carbon dioxide), and the chlorodiphenylborine was then distilled off, the yield being 12.4 g (70%): b.p. 119-120° (3 mm); d_4^{20} 1.1037.

Found %: B 5.50; C 72.15; H 5.01

$C_{12}H_{10}BCl$. Calculated %: B 5.40; C 71.89; H 4.99

By fractional distillation 5 g of propyl chloride and 12.9 g of phosphoryl chloride were isolated.

Chlorodi-1-naphthylborine. Isobutyl di-1-naphthylborinate (m. p. 102-104°) was prepared by the action of 1-naphthylmagnesium bromide on triisobutyl borate, and a portion (20 g) was warmed with benzene (20 ml) until dissolved. Phosphorus pentachloride (12.3 g) was added to the resulting solution in portions, and when reaction was complete isobutyl chloride and phosphoryl chloride were driven off at the water pump. Fractionation of the residue from a pear-shaped flask gave 12.6 g (70%) of chlorodi-1-naphthylborine, b.p. 213-215° (1.5 mm), in the form of a viscous oil.

Found %: B 3.50, Cl 11.45

$C_{20}H_{14}BCl$. Calculated %: B 3.60; Cl 11.82

SUMMARY

Diarylchloroborines were prepared by the action of phosphorus pentachloride on diarylborinic esters.

ORGANOBORON COMPOUNDS

COMMUNICATION 7. ACTION OF PHOSPHORUS PENTACHLORIDE ON ARENEBORONIC ESTERS. SYNTHESIS OF ARENECHLOROBORONIC ESTERS

B. M. Mikhailov and T. V. Kostroma

When an areneboronic ester is mixed with one equivalent of phosphorus pentachloride, reaction occurs with formation of an arenechloroboronic ester (an alkoxyarylchloroborine), an alkyl chloride, and phosphoryl chloride in accordance with the equation:

$$ArB(OR)_2 + PCl_5 = ArB\begin{matrix}Cl\\OR\end{matrix} + RCl + POCl_3$$

Ar = C_6H_5, o-$CH_3C_6H_4$.

By this method we prepared butyl benzenechloroboronate and isobutyl o-toluenechloroboronate from dibutyl benzeneboronate and diisobutyl o-tolueneboronate, respectively, these being the first representatives of a new type of boron compounds, in which boron is attached to an organic radical, halogen, and an alkoxy group.

EXPERIMENTAL

Butyl Benzenechloroboronate

Phosphorus pentachloride (41.7 g) was added in portions with constant vigorous agitation to 44.8 g (0.2 mole) of dibutyl benzeneboronate, contained in a Claisen flask. When the exothermic reaction was complete, butyl chloride and phosphoryl chloride were removed under reduced pressure (they were trapped in a coiled receiver cooled with solid carbon dioxide), and fractionation of the residue gave 29.5 g (75%) of butyl benzenechloroboronate, obtained as a colorless liquid b.p. 104-105° (9 mm) and d_4^{20} 0.9962.

Found %: B 5.61; Cl 18.3

$C_{10}H_{14}BOCl$. Calculated %: B 5.59; Cl 18.07

In addition, 17.4 g of butyl chloride and 27.4 g of phosphoryl chloride were obtained.

Isobutyl o-Toluenechloroboronate

Reaction was between 24.8 g (0.1 mole) of diisobutyl o-tolueneboronate and 20.8 g of phosphorus pentachloride. The procedure was as before.

Distillation gave 18.1 g (86%) of isobutyl o-toluenechloroboronate, b.p. 114-115° (10 mm), 110-111° (8 mm), in the form of a colorless liquid which fumed in air; d_4^{21} 0.9918.

Found %: B 5.40; Cl 16.3

$C_{11}H_{16}BOCl$. Calculated %: B 5.22; Cl 16.8

In addition, 8 g of isobutyl chloride and 11.7 g of phosphoryl chloride were obtained.

SUMMARY

When benzeneboronic and o-tolueneboronic esters were treated with phosphorus pentachloride, benzenechloroboronic and o-toluenechloroboronic esters were obtained, these being the first representatives of a new type of boron compounds.

REACTIONS OF HYDROGEN FLUORIDE WITH DIAZO KETONES

I. L. Knunyants, Ya. M. Kisel, and E. G. Bykhovskaya

In 1915 Nierenstein and coworkers made a detailed investigation of the reaction of diazomethane with carboxylic acid chlorides [1] and found that the main product was the corresponding halo ketone.

Later, in a study of this reaction, Arndt and coworkers [2], and shortly afterwards Robinson and Bradley [3], showed that, when an acid chloride was added slowly to excess of diazomethane, the corresponding diazo ketone was formed in good yield:

$$RCOCl + CH_2N_2 \longrightarrow RCOCHN_2 + HCl.$$

They succeeded in isolating diazo ketones in the pure state, and they showed that these substances react with hydrogen chloride or bromide in ether solution with formation of the corresponding chloro or bromo ketones [3].

In the present investigation we studied the possibility of obtaining fluoro ketones by the decomposition of diazo ketones with hydrogen fluoride, the diazo ketones examined being 2-diazoacetophenone and 2-diazo-4'-nitroacetophenone.

Although benzoyl chloride was added slowly to a very large excess (tenfold in some experiments) of diazomethane solution, we did not succeed in obtaining 2-diazoacetophenone in the pure state: it always contained about 19% of the chloro ketone. In the case of p-nitrobenzoyl chloride, the corresponding diazo ketone was obtained in the completely pure state.

Study of the reaction of these diazo ketones with hydrogen fluoride showed that treatment of their solutions in absolute ether with anhydrous hydrogen fluoride gave the corresponding fluoro ketones in almost quantitative yield:

$$ArCOCHN_2 + HF \longrightarrow ArCOCH_2F + N_2.$$

The reaction must be carried out in sufficiently dilute solution, otherwise considerable resinification occurs. A stoichiometric amount of hydrogen fluoride must be taken.

EXPERIMENTAL

I. Preparation of 2-Fluoroacetophenone

1. An ethereal solution of diazomethane (2 moles) was placed in a three-necked round-bottomed flask fitted with stirrer, thermometer, and dropping funnel. The contents of the flask were stirred vigorously at below 0°, and a solution of 40 g of benzoyl chloride in 40 ml of ether was dropped in slowly. Reaction occurred with vigorous evolution of nitrogen. When the addition was complete, the mixture was left overnight at room temperature; ether was then distilled off under reduced pressure. The diazo ketone obtained contained about 19% of chloroacetophenone; it was used in further reactions without purification.

2. Anhydrous hydrogen fluoride (7.8 g) was added to a cooled solution of 16 g of commercial diazoacetophenone (containing about 3.0 g of chloroacetophenone) in 150 ml of ether. Vigorous evolution of nitrogen occurred.

Ether was distilled off under reduced pressure, and the residue was carefully fractionated. The third distillation gave a fraction of b.p. 90-91° (12 mm). The 2-fluoroacetophenone so obtained is a colorless liquid having a pleasant floral odor and no lachrimatory effect. The yield was almost quantitative. It had d_{20}^{20} 1.154, n_D^{20} 1.5200; Found MR 36.03; Calculated MR 36.45. The properties of the substance obtained coincide with those of a preparation obtained by the action of fluoroacetyl chloride on benzene [4].

Found %: C 69.6 ; H 5.2; F 12.78
C_8H_7OF. Calculated %: C 69.5; H 5.1; F 13.75

II. Preparation of 2-Fluoro-4'-nitroacetophenone

1. 2-Diazo-4'-nitroacetophenone was prepared by the above-described procedure. For 2 moles of diazomethane, 20 g of p-nitrobenzoyl chloride was taken. The 2-diazo-4'-nitroacetophenone obtained, which crystallized immediately, was filtered off and washed with 50 ml of cold ether. The preparation contained practically no chlorine, which indicated the complete absence of 2-chloro-4'-nitroacetophenone as impurity. The yield was almost quantitative.

2. Anhydrous hydrogen fluoride (1.2 g) was added to 400 ml of an ethereal suspension of 10 g of 2-diazo-4'-nitroacetophenone contained in a flask fitted with reflux condenser. Slight warming was applied (temperature not above 25–30°). Dissolution of the diazo ketone and evolution of nitrogen continued for two hours. The very small insoluble residue that remained was filtered off. Ether was distilled off under reduced pressure, and white crystals then separated, which after two crystallizations from water melted at 133°. The yield was quantitative.

Found %: C 52.8; H 3.22; N 7.70; F 10.54
$C_8H_6O_3FN$. Calculated %: C 53.0; H 3.21; N 7.73; F 10.5

SUMMARY

The reaction between anhydrous hydrogen fluoride and diazo ketones was studied. It was shown that, when treated with hydrogen fluoride, 2-diazoacetophenone and 2-diazo-4'-nitroacetophenone give good yields of 2-fluoroacetophenone and the previously unknown 2-fluoro-4'-nitroacetophenone, respectively.

METATHETIC REACTIONS OF ACETALDEHYDE DIBUTYL ACETAL

M. F. Shostakovsky, N. A. Gershtain, and V. A. Neterman

It is well known that acetals readily undergo various reactions in which alkoxy groups are exchanged for other atoms and groups under the influence of acid reagents [1-10], but there are practically no data in the literature on the exchange of the aldehydes of acetals. There is only the report by Holmberg [11] of the replacement of benzaldehyde by formaldehyde in a series of mercaptals:

$$CH_2O + C_6H_5CH(SCH_2COOH)_2 \rightarrow CH_2(SCH_2COOH)_2 + C_6H_5CHO.$$

We have studied the reactions of acetaldehyde dibutyl acetal with various aldehydes and ketones, and we have found that the main direction of reaction is the replacement of the acetaldehyde in the acetal by other aldehydes and ketones with formation of the corresponding dibutyl acetals (transacetalation):

$$RCHO + CH_3CH(OC_4H_9)_2 \overset{H^+}{\rightleftharpoons} RCH(OC_4H_9)_2 + CH_3CHO;$$

Data on this reaction are given in Table 1.

TABLE 1

Data for Transacetalation Reaction

Aldehyde	Amount (g)	Amount of acetaldehyde dibutyl acetal (g)	Acetal obtained	Yield (g)	Yield (%)
C_2H_7CHO	43.26	50.0	$C_2H_7CH(OC_4H_9)_2$	47.15	80.31
C_6H_5CHO	63.66	52.49	$C_6H_5CH(OC_4H_9)_2$	31.36	44
	49.64	43.65		25.0	44
	71.65	60.9		14.85	18.6
	44.85	29.68		1.49	4.57

Note. Acetaldehyde was partially converted into crystalline paraldehyde.

In addition, high-boiling products were formed, and the structures of these have not yet been established. The amount of acetaldehyde that separated corresponded to the amounts of the new acetals formed. The reactions studied probably have a cation-chain mechanism, which is preceded by the equilibrium state of the acetals

, noted previously [6].

TABLE 2

*** In the reaction between benzaldehyde and acetaldehyde dibutyl acetal, a product having the following properties was isolated: b.p. 153-154° (mm); n_D^{20} 1.4906; d_4^{20} 0.9789; M 306.8, 306.1; %C 75.72; 75.90; %H 9.43; 9.39; We have not yet established its structure.

EXPERIMENTAL*

The preparation was carried out in a three-necked flask fitted with mechanical stirrer and reflux condenser. The aldehyde or ketone and acetaldehyde dibutyl acetal (the constants of which corresponded to data in the literature for the chemically pure substances) were taken in the molar ratio of 2:1; the catalyst was concentrated hydrochloric acid (0.5-1.0% on the total mass of the substances). The mixture was heated with constant stirring at about 70-100° for 3-4 hours and was then set aside for 12-24 hours. The acetaldehyde that separated was blown out of the system with a current of dry nitrogen and was trapped in coiled receivers cooled with dry ice in acetone (these were connected to the reflux condenser). The reaction products were vacuum-fractionated in a current of dry nitrogen. The low-boiling fractions consisted of unchanged aldehyde or ketone and acetaldehyde dibutyl acetal. After the first fractionation, the required acetal was treated with sodium and redistilled. The structures of the acetals formed were proved by the preparation of 2,4-dinitrophenylhydrazones, the melting points of which agreed with the literature data cited by Heilbron and Bunbury [15]; mixture tests showed no melting point depression. The constants and analytical data for the compounds obtained and their derivatives are given in Table 2.

We thank I. I. Zaretskaya for kindly supplying the 2,4-dinitrophenylhydrazones for the mixture tests.

SUMMARY

1. It was shown that, when aldehydes and ketones were treated with acetaldehyde dibutyl acetal, a transacetalation reaction occurred.

2. By this method the following compounds were synthesized from acetaldehyde dibutyl acetal: the dibutyl acetals of butyraldehyde, benzaldehyde, 2-furaldehyde, cyclohexanone, and acetophenone.

3. It was shown that this reaction is an equilibrium process and can be extended to the transacetalation of various acetals of a great variety of aldehydes and ketones.

CURRENT EVENTS

CHEMICAL CONFERENCES IN THE GERMAN FEDERAL REPUBLIC

I. ANNUAL MEETING OF THE GERMAN SOCIETY FOR THE INVESTIGATION OF FATS*

The annual meeting of the German Society for the Investigation of Fats was held on September 25-30, 1955, at Münster (Westphalia). In the program of the meeting the main attention was directed to natural fats and various products prepared from them. The following fundamental papers were read: "Oxidative Changes in Fats", "Edible Fats", "New Methods of Analysis for Fats and Substances prepared from them", "Technology of the Treatment of Fats — Machines and Apparatus", etc. There were also papers, which we shall list below, on synthetic material and methods for their preparation and analysis. The papers were read at two simultaneous sessions: 1) soaps and detergents, and 2) paints. The texts of the papers are published in the journal "Fette, Seifen, Anstrichmittel" in the issues of late 1955.

The papers read at the first session were: 1) P. Ommert (Marl) "Infrared Spectroscopy of Alkane- and Alkenesulfonates"; 2) J. Pfefferkorn (Münster) "The Electron Microscope and the Scope of its Application"; 3) W. Kling (Düsseldorf) "The Electron Microscope in the Analysis of Detergents"; 4) K. Pott (Stuttgart) "Practical Experience of Paper Chromatography in the Soap Field"; 5) M. Loury (Paris) "Methods of Calculating the McBain Diagram; 6) A. Petrov (Moscow) "Catalytic Polymerization of Propene"; 7) F. Wolbert (Münster) "Ultraviolet Spectroscopy of Alkylarenesulfonates and Sulfuric Esters of Fatty Alcohols"; 8) H. Thomas (Holzminden) "New Syntheses of Azulenes and their Application in Cosmetics".

The papers read at the second session were: 1) A. Seger (Münster) "Stagewise Hydrogenation of Polyalkynoic Acids"; 2) R. Milewski (Bochum) "Emulsions of Styrene-Butadiene Copolymers as Lacquers"; 3) H. Kaufmann and E. Gulinsky (Münster) "Electron Microscopy in the Paint Field"; 4) L. Korfhage (Hamburg) "New Developments in Epoxy-Resin Paints"; 5) H. Kaufmann and E. Gulinsky (Münster) "Automatic Recording of the Changes in Weight of Drying Paints. Porphine as a Diseccant"; 6) H. Kaufmann and H. Kirschnek (Münster) "Chlorides of Polyenic Acids and Polyenic Aldehydes".

After the meeting — from September 30 to October 3 — there was a practical seminar. The participants of the seminar were able to make themselves familiar with methods of microanalysis in the fat and detergent field, the determination of iodine and thiocyanogen values, methods of chromatography and the evaluation of the efficiency of detergents, methods for the automatic determination of the oxygen absorption of drying oils, rheological methods (viscometry and consistometry), electrometric methods (polarographic determination of antioxidants and the potentiometric determination of acid values), and optical methods (methods of spectroscopy and electron microscopy). Among the lectures that were given we will refer only to that of L. Korfhage on a very promising new type of paint medium. Epoxy resins have recently begun to be manufactured in large amounts. In Europe they are known under the trade name of "Epikotes", and in America under the name of "Epons". Their structure is represented by the formula (I), which shows that they are obtained by the condensation of epichlorohydrin

* This society (President, Prof. H. P. Kaufmann, Münster; Vice-President, Prof. G. Jacini, Milan) has now been transformed into an international society, and in view of this the next annual meeting (1956) will be held in Milan.

** This name was given in honor of one of A. Borodin's students, A. P. Dianin, who was the first to prepare this compound by the condensation of phenol with acetone.

(I)

Epikotes are readily esterified, both by fatty acids, such as the acids derived from castor, soybean, and other drying oils, and also by acids derived from nondrying oils, such as coconut oil and hydrogenated castor oil. They can be esterified also with mixtures of a fatty acid and abietic acid. The esterified Epikote resin can be represented by the formula (II).

(II)

II. Annual Meeting of the German Society for the Investigation of Petroleum and Coal Chemistry

The annual meeting of the society (president, Prof. K. Ziegler, Director of the Institute of Coal Chemistry, Mülheim) took place on October 6-8, 1955. There were five plenary and thirty-one sectional papers (read at two simultaneous sessions: coal and petroleum). Interesting papers were read by Prof. C. Padovani (Milan), who has this year been given the highest award of the Society – the Karl Engler Medal, Prof. E. Terres (Karlsruhe), Dr. H. Koch (Mülheim), and Prof. G. Hugel (Paris). Prof. C. Padovani outlined the development of the chemical treatment of fuel in Italy during the last twenty years. In the meeting of demands for thermal and electrical energy, the importance of solid fuel – home-produced low-calorific coal and imported coal – is gradually diminishing owing to increased utilization of natural gases and hydroelectric energy. More than 50% of the imported coal consists of high-quality coking and gas coals. The petroleum-refining industry, according to the speaker, has developed greatly in postwar years and is now in a very satisfactory state. The petrochemical industry is also growing. In one single petroleum-treating plant, 30,000 tons of gaseous olefins are produced anually and are then converted into various chemical products. Apart from its use as a source of energy, natural gas is being used in ever-increasing quantities for the synthesis of ammonia, methanol, and acetylene and its derivatives.

Prof. E. Terres's paper was devoted to adiabatic ignition temperatures and rates of oxidation of hydrocarbons of various structure. It was shown that the difference in ignition temperature between normal and branched hydrocarbons is only slight. The difference in the detonation stabilities of these hydrocarbons is to be explained entirely by their rates of oxidation. In the case of normal hydrocarbons, there is a rapid rise in oxidizability with increase in the length of the chain. The oxidation rates of detonation-stable branched paraffins are very low. There are other causes for detonation in a diesel engine. Detonation is here determined by the presence of two separate burning regions. One is the region of homogeneous mixtures of hydrocarbon paper and air. The other is the region of supersaturated fuel vapor and air, and it is in this that rapid combustion occurs.

Dr. H. Koch gave a description of a new method for the synthesis of fatty acids that has been developed in the Institute of Coal Chemistry, Mülheim. The acids are synthesized by the addition of carbon monoxide and water to olefins. The reaction proceeds under mild conditions: at low temperatures (0-30°) and relatively low pressures (30-100 atm). The complex formed by sulfuric acid with boron trifluoride is used as catalyst. It is essential to begin by reaction with carbon monoxide in absence of water, and then to add water. The reaction has been carried out with olefins from C_3 to C_{20}, but it goes particularly well with branched olefins: the dimer and trimer of isobutene and the tetramer of propene. An interesting starting material is oleic acid, which gives a dibasic acid containing 19 carbon atoms (nonylsebacic acid). This reaction is clearly a simplification and development of W. Reppe's reaction *, by which it was proposed to synthesize acids from olefins, carbon monoxide, and water at 230-250° and 200-300 atm over the catalysts nickel carbonyl or nickel carbonyl and nickel iodide.

* W. Reppe, Copenhaver, Bigelow, Acetylene and Carbon Monoxide Chemistry, N.Y., 1949, p. 265.

In his paper "Effect of Catalytic Processes on the Properties and Application of Lubricating Oils", Prof. Hugel devoted his main attention to sulfur compounds – both to their negative action (corrosion, poisoning of hydrogenating catalysts), and to their positive action (inhibiting action, with respect to acids of the lubricant, of mechanisms operating under severe conditions). It was established that the formation of a layer of metal sulfide that effects lubrication depends to a certain extent on the nature of the radicals of the sulfur compounds. Sulfur is particularly reactive when it is attached to allyl or benzyl: $CH_2=CH-CH_2-S$, $C_6H_5-CH_2-S$. Some chloro derivatives have a similar action to that of sulfur compounds, e.g. 1,4-dichloro-2-(2-chloro-1,1-bischloromethylethyl)benzene

A still greater effect is obtained by the simultaneous use of sulfur and chloro compounds, e.g. by addition to the oil of 2% of "dibenzylglycol xanthate" and 4% of 1,4-dichloro-2-(2-chloro-1,1-bischloromethylethyl)benzene. The widely used graphite and molybdenum sulfide have the disadvantage that the lubricant must be applied as a suspension, which is not always stable.

The author concluded that the lubricant must be soluble in hydrocarbons, it must be stable at medium temperatures and pressures, and at high temperatures and pressures the lubricant should decompose, and must leave a solid layer on the surface of the metal which ensures that lubrication will occur. These requirements can be satisfied only by complex metal compounds, particularly such compounds of molybdenum that decompose with separation of molybdenum sulfide. However, the synthesis of complex molybdenum compounds that are soluble in hydrocarbons is not a simple matter. The author has succeeded in solving this problem in different ways. It was established that it is not essential to introduce the required sulfur into the complex: it can be dissolved in the oil in the form of an active sulfur compound. In that case, instead of molybdenum sulfide, the oxides can be taken (molybdenum blue). There are forms of these oxides that are soluble in ether and butyl alcohol, but, until now, no preparations of molybdenum oxides were known that were soluble in hydrocarbons. It was shown that, when a higher alcohol, e.g. dodecyl, is added to a butyl alcohol solution of molybdenum blue and the butyl alcohol is then removed under reduced pressure, a form of molybdenum blue is obtained that is soluble in hydrocarbons. Molybdenum blue can be combined also with phosphoric acid. If, instead of phosphoric acid, we take a hydrocarbon-soluble derivative, e.g. (III)

(III)

and combine it with molybdenum blue, we again obtain a complex molybdenum compound that is soluble in oils. The corresponding derivative of phosphorothionic acid can also be taken, and it is then no longer necessary to introduce any other sulfur compound into the oil.

The program of the conference included a visit to Ludwigshafen. Seventy of the participants took part in the visit, but it was not possible for each of these to see what interested him. No meeting with W. Reppe and K. Pier was arranged. The affair was limited to an excursion around the works, a lecture on the origin of the firm, the showing of a film relating to works reconstruction after the war, and an inspection of two old production departments – for Carbide dyes and for Indanthren dyes.

The papers read at the conference in Karlsruhe are being published in Erdöl and Kohle and in Brennstoff-Chemie. I take this opportunity of passing on to Soviet chemists the invitation of the editorial boards of Fette, Seifen, Anstrichmittel and of Erdöl and Kohle to contribute to these journals, to which the chemists of France, Holland, Hungary, the German Democratic Republic, and other countries already contribute.

To NIKOLAI NIKOLAEVICH SEMENOV

Dear Nikolai Nikolaevich:

The Division of Chemical Sciences of the Academy of Sciences of the USSR and the Editorial Board of the Bulletin of the Academy of Sciences of the USSR, Division of Chemical Sciences, warmly congratulate you on the attainment of the age of sixty and the completion of forty years of scientific, pedagogical, and organizational activities.

Your name will always be associated with outstanding discoveries relating to chemical chain reactions and to the processes occurring during combustion, explosion and flame propagation. In your person, we salute also one who has long served as the Director of a leading Institute of the Division, the Institute of Chemical Physics of the Academy of Sciences of the USSR - a position in which you have shown outstanding initiative.

We hope, dear Nikolai Nikolaevich, that further great successes lie before you in all fields of your activity, and we wish you health and vigor in your creative labors.

KINETICS OF THE OXIDATION OF ACETALDEHYDE BY PEROXYACETIC ACID

R. F. Vasil'yev and N. M. Emanuel

Processes of oxidation with molecular oxygen belong to a class of chemical reactions that have a complicated mechanism. It was for this class of reactions that A. N. Bakh and K. Engler developed, in a particularly clear form, the concept of the important parts played by intermediate products and stages in chemical transformations. A new stage in the development of the theory of oxidative processes is associated with the introduction of the concept of a chain mechanism in these reactions. N. N. Semenov formulated the theory of degenerate branching, according to which peroxy compounds formed in the course of the reaction break down from time to time into radicals, which initiate new oxidation chains. This theory enables us to understand the slowness and autoacceleration of reactions between organic substances and molecular oxygen.

There can be no doubt that the direct oxidation of the substance by a peroxy compounds, i. e. by combined oxygen, is also worthy of attention. Such processes can occur both in systems in which oxidation by molecular oxygen is proceeding and the peroxy compounds is formed as an intermediary, and also in systems in which molecular oxygen is absent. The elucidation of the kinetics and mechanisms of processes of this kind presents much scientific and practical interest.

This paper is concerned with a study of the kinetics of the oxidation of acetaldehyde by peroxyacetic acid. In our choice of subject for investigation we were guided by the following considerations: a) reaction between an aldehyde and a peroxy acid is known to be one of the stages in the complex process of the oxidation of an aldehyde by molecular oxygen; b) the system aldehyde–peroxy acid is in itself a convenient model for the study of the kinetics and mechanism of oxidation by combined oxygen, for this process occurs comparatively readily and the number of reactants and products is small.

EXPERIMENTAL

Peroxyacetic acid was prepared from highly concentrated hydrogen peroxide and acetic anhydride by d'Ans and Frey's method [1]. The peroxyacetic acid content of the product was 70-82%, the remainder being acetic acid. It was kept at the temperature of dry ice (−78°) in a vessel having a ground-in stopper. It was shown that, when kept in this way, peroxyacetic acid does not undergo appreciable decomposition in the course of several months. The acetaldehyde solution was prepared from commercial acetaldehyde, which was dried over calcium chloride and distilled in a current of nitrogen into a vessel containing solvent. A freshly prepared solution was used on each occasion. Solvents were first distilled twice through a fractionation column. The cylindrical reaction vessels (diameter 15 mm, height 140 mm) were provided with ground-in stoppers and side arms through which nitrogen was passed in order to provide an inert atmosphere. In the temperature range 0° to −40°, a Dewar vessel containing acetone cooled with small portions of dry ice was used as a thermostat, constancy of temperature being maintained within ±0.3°. In the range 15-40°, a Heppler ultrathermostat, constant within ±0.03°, was used, and for experiments at 0° the reaction vessel was immersed in a Dewar vessel filled with melting ice.

Before a series of experiments, stock solutions of acetaldehyde and perox acetic acid were prepared. A definite amount (usually 10 ml) of the acetaldehyde solution was introduced into the reaction vessel immersed in the thermostat. When this solution had attained the temperature of the thermostat, a measured amount (usually 1-2 ml) of the peroxyacetic acid solution, also brought to the temperature of the thermostat, was added. The moment at which mixing occured was taken as the beginning of the reaction. Tests for chemical analysis were taken with a 0.36 ml thin-walled pipet. The concentration of peroxyacetic acid and peroxy product was determined by Kagan and Lyubarsky's method. Acetaldehyde was determined by titration of the hydrochloric acid liberated when the aldehyde reacted with hydroxylamine hydrochloride. A special method was developed for determining the acetic acid concentration. Experiments with artificial mixtures showed that, if the test samples were diluted with water, oxidation of aldehyde by peroxy acid continued during the analysis, and the values obtained for the acetic acid concentration were too high. We therefore diluted the test samples with potassium iodide solution. The peroxy acid was then immediately destroyed with liberation of iodine, and oxidation of the aldehyde was stopped. A definite volume of standard sulfuric acid was then added from a microburet, and iodine was titrated with thiosulfate solution. The total amount of acid was then titrated to phenolphthalein with alkali.

From the equation of the analytical reaction

$$CH_3COOOH + 2KI + H_2SO_4 = CH_3COOH + I_2 + K_2SO_4 + H_2O$$

and from the condition that the total amount of acid must be equal to the amount of alkali required in the titration, it is easy to determine the amount of acetic acid removed from the reaction vessel:

$$(CH_3COOH) = (OH^-)_{titr} - (H_2SO_4) + (CH_3COOOH)$$

in which (CH_3COOH) is the amount of acetic acid in the sample, $(OH^-)_{titr}$ is the amount of alkali required in the titration, and (CH_3COOOH) is the amount of peroxyacetic acid in the sample (all amounts are expressed as volumes of solutions of identical normality).

Theoretical and Experimental Kinetic Laws of the Reaction

It is known that the oxidation of aldehydes by peroxy acids results in the formation of carboxylic acids:

$$RCHO + RCOOOH \rightarrow 2RCOOH. \qquad (1)$$

Several workers (Kagan and Lyubarsky [2, 3], Bawn and Williamson [4], Meerwein and Bodendorf [5], who have studied these reactions, have shown that in the course of the oxidation process a new peroxy compound is formed and then disappears again, this compound being in equilibrium with the original reactants. Treating this compound as an intermediate product, they assumed the following scheme of reaction:

$$RCHO + RCOOOH \underset{k_3}{\overset{k_1}{\rightleftarrows}} Y \xrightarrow{k_2} 2RCOOH, \qquad (2)$$

in which Y is the intermediate peroxy compounds, and k_1, k_2, and k_3 are rate constants.

However, the observed behavior of the peroxy compounds cannot in itself serve as an unequivocal proof of the mechanism (2). The formation and subsequent decomposition of the new compound can be explained on the basis of a completely different mechanism, in which the acid is formed directly from the aldehyde and peroxy acid and the new peroxy compound is not an intermediary, but a by-product:

$$\begin{cases} RCHO + RCOOOH \underset{k_3}{\overset{k_1}{\rightleftarrows}} Y; \\ RCHO + RCOOOH \xrightarrow{k_2} 2RCOOH. \end{cases} \qquad (3)$$

This second possibility was not envisaged by the authors of these papers, although their experimental data agreed equally well with both of the mechanisms (2) and (3). Hence, the very likely hypothesis of a stagewise mechanism for the process was not provided with the necessary experimental proof.

However, the mechanisms (2) and (3) differ fundamentally, and it would be expected that the kinetics of the process would also be different. We have examined theoretically the character of the kinetic laws corresponding to the mechanisms (2) and (3) in order to find distinguishing features that would make it possible to make a choice between these two alternative reaction schemes. The simplest method for making such an examination consisted in assuming reaction laws of a simple type (first and second order) for the kinetics of the separate stages. Comparison of the results of the theoretical analysis with experiment fully justifies this assumption.

The mechanisms (2) and (3) correspond to the following systems of differential equations:

$$\begin{cases} \frac{d}{dt}(CH_3COOOH) = \frac{d}{dt}(CH_3CHO) = -k_1(CH_3COOOH)(CH_3CHO) + k_3(Y); \\ \frac{d}{dt}(Y) = k_1(CH_3COOOH)(CH_3CHO) - (k_2 + k_3)(Y); \\ \frac{d}{dt}(CH_3COOH) = 2k_2(Y). \end{cases} \qquad (4)$$

$$\begin{cases} \frac{d}{dt}(CH_3COOOH) = \frac{d}{dt}(CH_3CHO) = -(k_1 + k_3)(CH_3CHO)(CH_3COOOH) + k_2(Y); \\ \frac{d}{dt}(Y) = k_1(CH_3COOOH)(CH_3CHO) - k_2(Y); \\ \frac{d}{dt}(CH_3COOH) = 2k_3(CH_3COOOH)(CH_3CHO). \end{cases} \quad (5)$$

We could not obtain exact solutions of these equations because they are not linear. An approximate solution can be obtained on the assumption that one of the reactants (aldehyde) is in excess with respect to the other (peroxy acid). The equations then reduce to linear forms, and solutions are obtained as follows:

a) in the case of mechanism (2)

$$x = \frac{1}{m_2 - m_1}\left\{(m_2 - \alpha)e^{-m_1\tau} - (m_1 - \alpha)e^{-m_2\tau}\right\}. \quad (6)$$

$$y = \frac{\alpha}{m_2 - m_1}\left\{e^{-m_1\tau} - e^{-m_2\tau}\right\}. \quad (7)$$

$$z = 1 - \frac{1}{m_2 - m_1}\left\{m_2 e^{-m_1\tau} - m_1 e^{-m_2\tau}\right\}. \quad (8)$$

b) in the case of mechanism (3)

$$x = \frac{1}{l_2 - l_1}\left\{(1 - l_1)e^{-l_1\tau} - (1 - l_2)e^{-l_2\tau}\right\}. \quad (9)$$

$$y = \frac{\alpha}{l_2 - l_1}\left\{e^{-l_1\tau} - e^{-l_2\tau}\right\}. \quad (10)$$

$$z = 1 - \frac{1}{l_2 - l_1}\left\{(l_2 - \gamma)e^{-l_1\tau} - (l_1 - \gamma)e^{-l_2\tau}\right\}, \quad (11)$$

in which x, y, and z are concentrations of components relative to the initial concentration of peroxyacetic acid:

$$x = \frac{(CH_3COOOH)}{(CH_3COOOH)_0}; \quad y = \frac{(Y)}{(CH_3COOOH)_0}; \quad z = \frac{(CH_3COOH)}{2(CH_3COOOH)_0}; \quad (12)$$

the values of α, β, γ, and τ are defined by the expressions:

$$\alpha = \frac{k_1}{k_3}(CH_3CHO)_0; \quad \beta = \frac{k_2}{k_3}; \quad \gamma = \frac{k_2}{k_3}(CH_3CHO)_0; \quad \tau = k_3 t; \quad (13)$$

$-m_1$, $-m_2$, $-l_1$, and $-l_2$ are roots of the characteristic equations:

$$m^2 + (1 + \alpha + \beta)m + \alpha\beta = 0 \text{ and } l^2 + (1 + \alpha + \gamma)l + \gamma = 0.$$

Fig. 1. Theoretical kinetic curves corresponding to the mechanism (2) constructed according to Equations 6, 7, and 8; x, y, and z are the relative concentrations of peroxyacetic acid, intermediate peroxy compound, and acetic acid, respectively. The curves are plotted for the following values of the parameters: ——— $\alpha = 10$, $\beta = 0.1$; – – – – $\alpha = 1$, $\beta = 1$.

Fig. 2. Theoretical kinetic curves corresponding to the mechanism (3) constructed according to Equations 9, 10, and 11; x, y, and z are the relative concentrations of peroxyacetic acid, by-product peroxy compound, and acetic acid, respectively. The curves are plotted for the following values of the parameters: ——— $\alpha = 10$, $\gamma = 1$; – – – – $\alpha = 1$, $\gamma = 1$.

By way of example, Figures 1 and 2 give the theoretical kinetic curves plotted according to Equations 6-8 and 9-11 respectively, definite values being taken for the parameters α, β, and γ [i.e. so that definite relationships exist between the constants k_1, k_2, and k_3 and the concentration $(CH_3CHO)_0$]. As will be seen from Figures 1 and 2, the kinetic curves for peroxyacetic acid and the peroxy intermediary or by-product are qualitatively alike in the two cases. A qualitative difference in the form of the kinetic curves is found only for the final product, acetic acid. In the case of the mechanism (3) the acid accumulates according to a curve of a simple type, but in the case of the stagewise mechanism (2) the kinetic curve for the final product has an autocatalytic form. As can be readily shown by calculation, the inflection on the curve occurs at the point at which not more than 26% conversion has been attained.

The curves for the accumulation of acid coincide with the kinetic curves for the fall in the overall amount of active oxygen, i. e. the oxygen present both in the form of peroxy acid and peroxy intermediary or by-product, as follows from the general balance of the reactions in the stoichiometric equations (2) and (3). A comparison of the kinetic curves in Figures 1 and 2 leads to the conclusion that a choice between the mechanisms (2) and (3) can be made only on the basis of a study of the kinetics of the formation of acetic acid or the kinetics of the overall loss of active oxygen.

It is interesting to note that in investigations devoted to the oxidation of aldehydes by peroxy acids, the kinetics of acid formation have received practically no study. The paper of Bawn and Williamson [4] gives data on the overall loss of active oxygen in the reaction between acetaldehyde and peroxyacetic acid. The authors favor the concept of an intermediate stage [mechanism (2)]. Unfortunately, the number of experimental points is not sufficient for the course of the curve to be followed in detail, and the overall loss of active oxygen is represented by a curve of a simple type. Wittig and Pieper [6] studied the kinetics of the formation of benzoic acid and the consumption of peroxybenzoic acid in the oxidation of benzaldehyde. The kinetic curves given in the paper are of the simple type. However, the absence of experimental points on the kinetic curves makes it impossible for us to judge the accuracy to which the form of the curves was established. Thus, the experimental data presented by these authors corresponds most closely to the mechanism (3), in spite of the fact that they consider that the reaction proceeds by the stagewise mechanism (2).

Essentially, therefore, the question of the mechanism of the reaction and the part played in it by the

peroxy compound formed during the reaction remains unresolved. We have therefore made a special study of the kinetics of the formation of acetic acid. The experiments were carried out in toluene solution at close to room temperature. Most of the experiments were carried out with an 8 to 15-fold excess of aldehyde with respect to peroxy acid, i.e. under the conditions under which Equations 6-11 are valid.

Figures 3 and 4 give the results of our study of the kinetics of the formation of acetic acid and the kinetics of the diminution in the sum of the concentrations of peroxyacetic acid and the peroxy product (i.e. in the overall concentration of active oxygen). It will be seen from these curves that the experimental points characterizing the two relationships are almost in coincidence. This coincidence of the two relationships enables us to use two sets of experimental data obtained independently of one another for the construction of a single kinetic curve, so that the form of this curve can be established with greater accuracy.

Fig. 3. Kinetics of the formation of acid (left scale, black points) and of the diminution in overall concentration of peroxy compounds (right scale, white points) in toluene solution. Initial concentrations: aldehyde 1.29 moles/liter, peroxy acid 0.10 mole/liter. Curves plotted from Equation 8.

Fig. 4. Initial sections of the kinetic curves in Fig. 3. The curves have been displaced to different extents along the axis of ordinates; the scale for the measurement of degree of conversion is indicated. The numbering and signs correspond to Fig. 3.

TABLE 1

Experiment No.	Temperature °C	α	β	$k_2 \cdot 10^4$ (sec^{-1})
1	17.9	12.0	0.6	0.99
2	23.4	9.8	0.8	1.1
3	33.7	7.1	0.9	2.6
4	39.5	5.8	1.1	3.8

As will be seen from Fig. 4, the formation of acetic acid proceeds with initial acceleration. A qualitative examination of the curves for the formation of acid therefore supports the mechanism (2). The curves in Figures 3 and 4 were plotted from Equation 8, being fitted to the experimental points by suitable choice of the parameters α, β, and k_2. Calculation of k_2 was based on a simple transformation of the kinetic curves by a change in the scale of the time axis. The parameter k_2, therefore, does not affect the form of the curve. The parameter $\alpha = \frac{k_1}{k_2}(CH_3CHO)_0 = \frac{(CH_3CHO)_0}{K}$ depends on the initial acetaldehyde concentration and the value of the equilibrium constant. The latter was determined in independent experiments (see below). The parameter α, therefore, was known beforehand. The parameter β was found by selecting a value that resulted in satisfactory fitting of the theoretical curve to the experimental points.

Table 1 gives the values of the parameters for the four experiments of this series, which were carried out at different temperatures.

The data in Table 1 in conjunction with Equation 7 can be used also for the construction of theoretical

Fig. 5. Theoretical kinetic curves for the intermediate product, plotted from Equation 7 with the parameters given in Table 1. The points on the curves are the results of determinations of the concentration of intermediate product; they were not used for the construction of the curves. The numbering and signs correspond to Figures 3 and 4.

curves for the intermediate product. These curves are shown in Fig. 5. The points distributed along the curves represent the results of special determinations of the concentrations of the intermediate product in the respective experiments; they were not used for the construction of the curves. In all cases the fitting of the experimental points to the theoretical curves is quite satisfactory. This result provides a quantitative proof of the correctness of the mechanism (2).

Thus, the qualitative form of the kinetic curve for the formation of acid (initial acceleration), the close fit of the experimental points to the theoretical curves, and the possibility of calculating the changing concentrations of the intermediary from the kinetics of the formation of the final product have enabled us to solve the problem of the reaction mechanism. It can be considered to be established that the oxidation of acetaldehyde by peroxyacetic acid proceeds in stages via the formation and subsequent decomposition of an intermediate peroxy compound; i.e. that it proceeds in accordance with the mechanism (2). By the use of the parameters given in Table 1 and Equations 13, the rate constants k_1 and k_3 can be evaluated at each temperature. The rate constants found in this way for a given series of experiments are closely in accord with the Arrhenius law $k = ae^{-E/RT}$, but they vary from series to series. Unsatisfactory reproducibility of the values of rate constants has been noted by other workers on oxidation by peroxy acids [7]. In particular, the reaction of acid formation is sometimes retarded to such an extent that only the first stage is realized for practical purposes. The preexponential factor is less by a factor of several powers of ten than the usual values of about 10^{11} liter/mole·second or 10^{13} second^{-1} ($a_1 \sim 10^2 - 10^5$ liter/mole·second, $a_3 \sim 10^5 - 10^8$ second^{-1}, and $a_3 \sim 10^8$ second^{-1}), so that they cannot be treated within the framework of the usual collision theory for bimolecular reactions or in terms of bond-vibration frequencies in the case of unimolecular reactions. Moreover, the activation energies of the individual stages ($E_1 \sim 7, E_2 \sim 13, E_3 \sim 17$ kcal/mole) are very much less than the values characteristic for reactions between saturated molecules (several tens of kilocalories [8]).

The detailed mechanism of the reaction studied is probably more complex than that indicated in the overall scheme (2). It is possible that a chain reaction occurs. The experimentally determined rate constants may then be related in a complex manner with the constants for the elementary processes. For this reason, both the preexponential factors and the activation energies, which are combinations of the corresponding characteristics of the elementary stages, may differ substantially from the usual values *.

It must again be emphasized, however, that the chemical mechanism (2) closely represents the kinetics of the overall reaction and leads to conclusions that are in accord with the laws found experimentally. These laws are as follows:

1. The kinetics of the formation of acetic acid and the diminution in total active oxygen are described by Equation 8, the point of inflection occurring at about 25% conversion.

2. The concentration of the intermediate product varies with time in accordance with Equation 7. The fact that suitable treatment of data on the kinetics of formation of the final product enables to calculate correct-

* There is another possible cause for the low value of the preexponential factor for the reaction resulting in the formation of the intermediate product - the low steric factor ($10^{-3} - 10^{-5}$) associated with addition reactions.

TABLE 2

Temp. (°C)	Concentration* (mole/liter) $(CH_3CHO)_0$	$(CH_3COOH)_0$	$(CH_3COOH)_\infty$	K (mole/liter)
−20	0.0948	0.0313	0.0013	0.028
−20	0.330	0.436	0.0038	0.025
0.0	0.281	0.0370	0.0000	0.052

0.0	0.330	0.0436	0.0076	0.061
+19.3	0.284	0.0370	0.0122	0.128
+19.3	0.281	0.0370	0.0112	0.113
+20.1	0.330	0.0475	0.0139	0.122
+30.4	0.330	0.0436	0.0165	0.187

* The values of concentration correspond to 20°. In the calculations the dependence of the density of toluene on temperature was taken into account.

ly the kinetic curves for the intermediate product shows that we may exclude the possibility that this peroxy compound is actually a by-product and that the initial acceleration on the kinetic curve for the acid is due to the complex mechanism by which it is formed from the original reactants. It will be clear that, if this were true, there would be no correlation between the two processes indicated above.

3. The rate constants obey the Arrhenius law, and the temperature coefficient for the formation of acid is greater than that for the formation of the intermediate peroxy compound. Experiment shows that there is a powerful temperature effect associated with the retardation of the second stage. Thus, at low temperatures, (−40-0°) practically no acetic acid is formed, and the reaction consists only in the establishment of the equilibrium:

$$CH_3CHO + CH_3COOOH \rightleftharpoons Y.$$

Fig. 6. Equilibrium constant for the formation of intermediate product as a function of temperature.

4. The rate of formation of the intermediate product is proportional to the product of the concentrations of peroxy acid and aldehyde. That the reaction is of first order with respect to the peroxy acid follows from the applicability of Equations 6-8 in the description of the kinetics of the process. As the aldehyde was in excess in the above-described series of experiments, special experiments were carried out at lower concentrations. When the acetaldehyde concentration was changed by a factor of six, the bimolecular constant k_1 changed by only 6%, which indicated a first-order reaction with respect to aldehyde concentration. It is probable that, in this reaction, we are dealing with a complex process that simulates a simple one having simple kinetic laws.

We also obtained confirmation of the suggestion made by other authors [2-4] that an equilibrium exists between the intermediate peroxy compound and the original reactants. The equilibrium constant was determined in those experiments in which the stage of acetic acid formation was retarded. The experiments were carried out in toluene solution.

Table 2 gives the data for, and the results of, the calculation of equilibrium constants from the formula:

$$K = \frac{k_2}{k_1} = \frac{(CH_3CHO)_{eq}\,(CH_3COOOH)_{eq}}{(Y)_{eq}} =$$

$$= \frac{(CH_3CHO)_0 - (CH_3COOOH)_0 + (CH_3COOOH)_{eq}}{(CH_3COOOH)_0 - (CH_3COOOH)_{eq}} \cdot (CH_3COOOH)_{eq},$$

in which ( )$_0$ indicates initial concentrations and ( )$_{eq}$ indicates final concentrations (at the equilibrium state).

A linear relationship is found between the logarithm of the equilibrium constant and the reciprocal of the temperature (Fig. 6), and this permits us to write the following expression for the equilibrium constant:

$$K = 1.6 \cdot 10^5 \cdot e^{-\frac{5500}{RT}} \text{ mole/liter.}$$

The formation of the intermediate product is therefore accompanied by the evolution of 5.5 kcal/mole. Estimates of heat of reaction on the basis of mean bond energies give the following values for structures suggested in the literature for the intermediate peroxy compound:

I. 1-Hydroxyethyl peroxyacetate (Wieland [9], Kagan and Lyubarsky [2, 3]):

$Q_{calc} = -10$ kcal/mole

II. 1-Hydroperoxyethyl acetate (Bawn and Williamson [4]):

$Q_{calc} = -10$ kcal/mole

III. An isoozonide (Wittig and Pieper [6]):

$Q_{calc} = -20$ kcal/mole

The error in such a calculation is of course large, and it may therefore be considered that the experimental value is in accord with the theoretical estimate.

SUMMARY

1. On a basis of a comparison of the theoretical and experimental kinetic laws it was shown that the oxidation of acetaldehyde by peroxyacetic acid proceeds in two stages:

a) reversible formation of an intermediate peroxy compound:

$$CH_3CHO + CH_3COOOH \rightleftharpoons Y,$$

b) decomposition of the intermediate compound into the final product, acetic acid:

$$Y \rightarrow 2CH_3COOOH.$$

2. A study was made of the equilibrium of the reversible reaction resulting in the formation of the intermediate product, and it was shown that the reaction is exothermic, the heat of reaction being 5.5 kcal/mole.

SPECTROSCOPIC STUDY OF THE INTERMEDIATE PRODUCT AND INTERMEDIATE STAGE OF REACTION IN THE OXIDATION OF ACETALDEHYDE BY PEROXYACETIC ACID

R. F. Vasilyev, A. N. Terenin, and N. M. Emanuel

Physical methods of investigation have not yet received adequate application in the study of the processes of liquid-phase oxidation by molecular oxygen, and they have not been applied in the study of oxidation by peroxy compounds (i.e. one of the stages in the process of oxidation by molecular oxygen). However, the chemical analysis and identification of individual peroxy compounds taking part in these processes, which have complex mechanisms, comprise a difficult problem that cannot always be solved. There can be no doubt that in this fact lies one of the causes of the inadequate study given to the chemistry of oxidation processes. It is not surprising, therefore, that papers should appear relating to investigations having the object of developing physical methods for the analysis and identification of peroxy compounds, e.g. spectroscopic [1-3] and polarographic [4] methods. It was with this object that systematic studies recently began to be made of various peroxy compounds. Infrared spectra were determined for some dozens of peroxy compounds of various classes [1, 2, 5, 8, 9]. The results obtained were applied in the study of the photochemical [9, 10] and thermal [3] oxidation of aldehydes by molecular oxygen, and in these processes intermediate products - peroxy acids - were detected, and the kinetics of their formation and further transformation were studied.

In the spectra of all of the peroxy compounds absorption bands were found in the frequency range 800-900 cm^{-1}. These bands were ascribed to the valency vibrations of the peroxide linkage $-O-O-$. Theoretically, such an assignment is not well founded, for the vibration at a peroxide linkage is not characteristic [2, 8, 11]. Moreover, other vibrations may also appear in this range (deformational vibrations of the CH_3 group, vibrations of the molecule as a whole, etc.). Actually, it is found that a few bands in the 800-900 cm^{-1} region occur in the spectra of many peroxides.

As these bands are present in the spectra of all peroxy compounds investigated up to the present time, it appears that the presence of an absorption band in the 800-900 cm^{-1} region is a distinguishing feature for peroxy compounds. In the vibration corresponding to this band, not only the $-O-O-$ link takes part, but also neighboring linkages. The position of the absorption band therefore varies (over a range of 100-120 cm^{-1}) according to the structure of the peroxy compound.

We have examined the possibility of applying the spectroscopic method for the study of processes of oxidation by peroxy compounds. As subject for study we selected the oxidation of acetaldehyde by peroxyacetic acid. In so doing we were guided by the following considerations:

a) reaction between aldehydes and peroxy acids is known to be one of the stages in the complex process of the oxidation of aldehydes by molecular oxygen;

b) as a result of work by Soviet and foreign investigators [12-14] it has been established that the reaction selected proceeds stagewise via intermediate formation and subsequent decomposition of an intermediate peroxy compound (Y):

$$CH_3CHO + CH_3COOOH \rightleftharpoons Y \longrightarrow 2CH_3COOH;$$

c) the infrared spectra of the original reactants and the final products are comparatively simple and

are well known in the literature.

Particular interest was presented by a study of the intermediate stage and intermediate reaction product with the aid of infrared spectroscopy. In its relation to this study, the difference in the position of the −O−O− absorption band in different compounds was regarded by us as a favorable circumstance, since such a difference might insure satisfactory spectroscopic detection of the intermediate peroxy compound in presence of the original peroxy acid. We may point out that the solution of such a problem by chemical methods is often impossible, since the original and intermediate peroxy compound generally have identical chemical properties. Hence, the possibility cannot be excluded that many reactions of this kind that are regarded as simple are in fact processes that proceed in stages.

Kinetic experiments have established that the intermediate peroxy compound is an equimolecular addition product of acetaldehyde and peroxyacetic acid [12-14]. Structural formulas have been proposed in the literature for this compound:

1) 1-Hydroxyethyl peroxyacetate [12]:

2) 1-Hydroperoxyethyl acetate [13]:

3) An isoozonide [15]:

No proof has been advanced for any of these possible structures by the authors who postulated them.

Since the intermediate product is a peroxy compound, it was natural to seek its spectral characteristics in the region of the frequencies of the −O−O− link (800-900 cm^{-1}). As solvent we selected nitromethane, which has a strong but narrow absorption band at 920 cm^{-1} and some other very weak bands in this region. The spectra were determined on an IKS-11 infrared spectrometer having a rock salt prism. The solutions were held in a cell having rock salt windows or in a special cell having polyethylene windows; the latter is the more convenient in work with solutions of such a corrosive substance as peroxyacetic acid. The work was carried out in two stages: preparation of the intermediate product, and the determination of its spectrum. The method of preparing the intermediate product is described in the literature [16]. When toluene solutions of acetaldehyde and peroxyacetic acid are mixed and the mixture is placed in a cryostat, after several hours at −40° to −50° crystals of the intermediate peroxy compound are precipitated (m.p. −19° to −20°). This process is extremely sensitive to variations from optimum concentrations and to impurities (in particular, water). We carried out this preparation, poured the mother liquor from the precipitate, and dried the crystals with the aid of ether. We then dissolved part of the product in nitromethane, filled a cell with the solution, and determined its spectrum. All possible measures were taken to keep the solution at room temperature for as short a time as possible: a portion of the precipitate was dissolved in cooled solvent, the test sample was taken in a cooled pipet, and the time taken to determine the spectrum was confined to a few minutes.

The results are presented in Fig. 1. In the spectrum of the solution of the precipitate powerful absorption is to be clearly observed at a wave number of 847 cm^{-1}, at a place in which the original reactants and final products (acetaldehyde, peroxyacetic acid, and acetic acid) do not have absorption bands. The new

Fig. 1. Spectra of solutions of original reactants, final product, and reacting mixture in the region of the valency vibrations of the −O−O− link: 1) acetaldehyde (0.6 mole/liter); 2) peroxyacetic acid (1.2 moles/liter); 3) acetic acid (1.5 moles/liter); 4) reacting mixture. Thickness of absorbing layer 0.1 mm. Solvent, nitromethane. The broken line indicates the region of the absorption of the solvent.

Fig. 2. Summation spectrum of solutions of acetaldehyde and peroxyacetic acid in nitromethane (1), and the spectrum of the reacting mixture (2) (in the region of the valency vibrations of the −O−O− link). band partially overlaps the absorption bands of peroxyacetic acid and acetaldehyde (wave number of both of these bands: 856 cm^{-1}) resulting in a characteristic contour having an inflection. When the spectrum is determined on samples that have been kept for 20-30 minutes at room temperature (in the course of this time the intermediate product disappears, being decomposed into acetic acid), the 847 cm^{-1} absorption band is no longer present. This indicates that the new absorption band is definitely not due to foreign substances (such as ether and toluene).

The band of the intermediate product at 847 cm^{-1} was found also in the spectrum obtained when the reaction was carried out directly in nitromethane (without isolation of the crystals). This spectrum is given in Fig. 2. This figure shows also the summation spectrum of aldehyde and peroxy acid solutions. Both spectra were determined in a double cell. Comparison of the spectra shows that the appearance of the 847 cm^{-1} band cannot be explained as the result of the superposition of the bands of the original reactants.

There can be no doubt that the band that we have found at 847 cm^{-1} is an absorption band of the intermediate peroxy compound. It is probably to be attributed to valency vibrations of the −O−O− link. The displacement by 9 cm^{-1} from the spectrum of peroxyacetic acid must be regarded as small when it is considered that the corresponding bands in the spectra of the peroxy compounds that have now been investigated are distributed over a wide range (100-120 cm^{-1}). This result indicates that the change in structure undergone by the molecule does not have a great effect on the dynamics and kinematics of the vibrations of the peroxy link. It may be assumed that this effect will be small when the intermediate product, like peroxyacetic acid, contains a hydroperoxy group, and will not be so small when the hydroperoxy group is converted into peroxy (i.e. to peroxy linked to carbon at both sides) in the course of the reaction *.

In view of the spectroscopic results therefore, of the three structures proposed in the literature for the intermediate compound the most probable is that postulated by Bawn and Williamson - 1-hydroperoxyethyl acetate:

* Data in the literature give convincing support to this view. Karyakin and Nikitin [1] observed only small displacements of bands in the region 800-900 cm^{-1} in a series of cyclic hydroperoxides, but could not distinguish bands that preserved their position in a series of peroxides. According to Minkov's results [2] on the spectra of about thirty peroxides and hydroperoxides, the most intensive bands are distributed as follows: in the spectra of peroxides - in the range 820-890 cm^{-1}; in the spectra of hydroperoxides - in the much narrower range 835-855 cm^{-1}.

We did not succeed in determining the band of the intermediate product in the isolated state, since a considerable move toward equilibrium between it and the original reactants always occurred during its dissolution in nitromethane, so that acetaldehyde and peroxyacetic acid were always present in the solution.

The low intensity of the band and the overlapping of this band and that of peroxyacetic acid made it impossible to determine concentrations quantitatively by spectrum analysis. Nevertheless, from the spectrum of the reacting mixture we succeeded in following qualitatively the kinetics of the establishment of equilibrium between the original reactants and the intermediate peroxy compound and the kinetics of the reaction leading to the formation of acid.

Fig. 3. Spectra of reacting mixture: 1) immediately after dissolution of crystals in nitromethane; 2) 11 minutes after dissolution; 3) after 23 minutes; 4) after 68 minutes; 5) after 73 minutes. Thickness of absorbing layer - 0.1 mm. Temperature - -10°.

Fig. 4. Spectra of reacting mixture: 1) immediately after dissolution of intermediate product; 2) 9 minutes after dissolution; 3) after 22 minutes; 4) after 50 minutes; 5) after 80 minutes. Thickness of absorbing layer - 0.1 mm. Temperature - +20°.

Fig. 5. Spectra of reacting mixture: 1) immediately after dissolution of intermediate product; 2) after 21 minutes; 3) after 41 minutes; 4) after 54 minutes. Room temperature.

Figures 3 and 4 give the results of two experiments, carried out at −10° and +20° respectively. In both experiments the intermediate product, which separated in the form of crystals, was dissolved in nitromethane. The resulting solution was placed in a thermostat (−10° or +20°), test samples were transferred to the cell, and the spectrum was recorded.

In experiments on the kinetics of the oxidation of acetaldehyde by peroxyacetic acid [14] it was established that the temperature coefficients for the reactions of formation of the intermediate product and its decomposition into the original reactants are less than the temperature coefficient for the reaction of formation

of acetic acid. For this reason, scarcely any acetic acid is formed at −10°, and reaction consists only in the establishment of equilibrium between the original reactants and the intermediate peroxy compound. Accordingly, the intensity of the band of the intermediate product (847 cm^{-1}) diminishes relative to that of the peroxyacetic acid band (856 cm^{-1}) and finally takes up a constant value (Fig. 3). At 20° establishment of equilibrium and decomposition of the intermediate product into acid proceed simultaneously, the first process being the more rapid so that the intensity of the band due to the intermediate product diminishes at first, and then also that due to peroxyacetic acid diminishes (Fig. 4).

Fig. 5 shows a series of spectrograms taken in succession over a wider range of frequencies. The solution from which the test samples were taken was at room temperature. The gradual disappearance of the absorption bands of peroxyacetic acid (856 cm^{-1}), the intermediate product (847 cm^{-1}), and acetaldehyde (847 cm^{-1}) can be clearly seen.

SUMMARY

1. The intermediate product formed in the oxidation of acetaldehyde by peroxyacetic acid was isolated in the form of crystals. A band at 847 cm^{-1} was found in the absorption spectrum of its solution, and this was ascribed to the vibration of the peroxy link in the molecule of the intermediate product.

2. The variation of the spectrum of the reacting mixture with time is in full accord with a stagewise reaction mechanism. The presence of an intermediate stage and an intermediate product is quite clearly manifest in the spectrum - a fact that indicates that the application of infrared spectroscopy to the study of oxidation by peroxy compounds forms a promising line of attack on this problem.

EFFECT OF SOLVENTS ON THE RATE OF OXIDATION OF ACETALDEHYDE BY PEROXYACETIC ACID FROM THE POINT OF VIEW OF INTERMOLECULAR HYDROGEN BONDING

R. F. Vasil'yev, A. N. Terenin, and N. M. Emanuel

Whenever a study is made of the kinetics of a reaction in solution, the question of the effect of the solvent on the rate and mechanism of the process is bound to arise. It then becomes important to determine how the observed effect of the solvent arises.

We have carried out experiments on the kinetics of the oxidation of acetaldehyde by peroxyacetic acid in eight different solvents: carbon tetrachloride, chloroform, toluene, benzene, nitrobenzene, methanol, nitromethane, and acetone. The reaction between peroxyacetic acid and acetaldehyde results in the formation of acetic acid, and it occurs in stages via the reversible formation and subsequent decomposition of an intermediate peroxy compound Y [1]:

$$CH_3COOOH + CH_3CHO \rightleftharpoons Y \longrightarrow 2CH_3COOH.$$

With the object of obtaining reproducible results, we adopted the procedure of diluting stock solutions with solvents. As stock solutions we prepared solutions of peroxyacetic acid and acetaldehyde in toluene. At the beginning of an experiment 1.5 ml of the aldehyde stock solution was diluted with 10 ml of solvent, and 0.5 ml of peroxy acid stock solution was then mixed in. Hence, all of the experiments were carried out with the same solutions, and the solvent whose effect was being studied comprised about 84% of the volume of the reacting mixture. This procedure made it possible to compare quantitatively the rates of the process in various solvents. Kinetic measurements were made for diminution in the amounts of peroxyacetic acid and in total active oxygen, i.e. the active oxygen present both as peroxyacetic acid and as intermediate product. Stoichiometric considerations show that the latter kinetic relationship is identical with the kinetics of acetic acid formation.

The experimental results are shown in Fig. 1, from which it will be seen that the rate at which peroxyacetic acid is used up is identical in chloroform, toluene, benzene, and nitrobenzene; the rate is somewhat higher in carbon tetrachloride. In all of these solvents the formation of the intermediate peroxy compound proceeds to approximately the same degree of transformation, namely 70-78%. The rate at which the intermediate peroxy compound is formed in methanol, nitromethane, and acetone* is very much less than in the solvents of the first group.

In all of the solvents the two stages of the reaction are clearly marked. The solvents vary in their effects on the rates of the two stages. For example, the intermediate product is formed more slowly in methanol than in solvents of the first group, whereas the rate of the decomposition of the intermediate product into acid is higher in methanol than in any of the other solvents.

Our experimental results on the dependence of the course of the reaction on the identity of the solvent

* Special experiments showed that acetone is not oxidized by peroxyacetic acid at 24.2°.

Thickness of layer - 0.1 mm.

can be interpreted as follows. The molecular structure of the solvents in which the first stage of reaction is slow (methanol, acetone, nitromethane) is such that hydrogen bonding is possible between the solvent molecule and the molecule of peroxyacetic acid. A hydrogen bond can be formed between the hydroxyl group of the peroxy acid on the one hand and the hydroxyl, carbonyl, or nitro group of the solvent on the other. The possibility of the formation of a second hydrogen bond cannot be excluded, i.e. between the carbonyl group of the per-

oxy acid and the hydroxyl groups of the solvents. For the remaining solvents (with the exception of nitrobenzene) we may state before hand that the formation of such hydrogen bridges is impossible on account of the absence of suitable structural groups.

The presence of solvent molecules linked to reactant molecules by hydrogen bonds can affect reaction rate. The kinetic detection of a hydrogen bond was considered in investigations by one of us and coworkers [2, 3]. In these investigations it was established that in certain cases hydrogen bonding has a great effect on the kinetics of chemical reactions. In particular, it was found that it was possible to detect intermolecular hydrogen bonding by kinetic methods [4]. In our case, solvent molecules hydrogen-bonded to peroxyacetic acid molecules can reduce the accessibility of the latter to acetaldehyde molecules and so bring about a reduction in reaction rate.

As is well known, the most reliable method for establishing the presence of a hydrogen bond consists in a study of the vibration spectra (infrared and Raman) of suitable mixtures [5]. Hydrogen bonding causes a displacement and broadening in the bands of the links concerned in the hydrogen-bond formation. For example, the wave number of the vibrations of a hydroxyl in any compound is 3600-3750 cm^{-1}, which is reduced when the hydroxyl is hydrogen-bonded to 3000-3500 cm^{-1}, depending on the strength of the hydrogen bond. We studied the infrared absorption spectra of peroxyacetic acid solutions in the range 3000-3500 cm^{-1}. The infrared spectra were recorded with an IKS-11 infrared spectrometer having a lithium fluoride prism. The solvents used were equimolecular mixtures of toluene with nitromethane, nitrobenzene, and acetone. The spectrum of a solution of the peroxy acid in methanol was not determined because the solvent itself absorbs strongly in this region of the spectrum owing to association due to hydrogen bonding. The spectra obtained are given in Fig. 2. In toluene solution in this region of the spectrum there is an absorption band at 3310 cm^{-1}, which must be attributed to an intramolecular hydrogen bond formed in molecules of aliphatic peroxy acids [6, 7]:

(the wave number of the "free", i.e. not hydrogen-bonded, hydroxyl is in this case 3600 cm^{-1}).

When nitromethane is added to a toluene solution of peroxyacetic acid, a new band (3385 cm^{-1}) appears which is present neither in the toluene spectrum nor in the nitromethane spectrum. We attribute this band to the vibrations of the hydroxyl group of the peroxy acid, which is hydrogen-bonded to the nitromethane molecule. We consider that in some of the peroxy acid molecules the intramolecular hydrogen bond is broken and the "freed" hydroxyl group attaches itself to an oxygen atom of nitromethane:

When acetone is added to a toluene solution of peroxyacetic acid, considerable changes occur in the spectrum: the band broadens and increases in intensity, and its maximum is displaced toward the long waves, and takes up the position 3265 cm^{-1}. Since pure acetone does not absorb in this region it is natural to assume that the new absorption band is associated with a hydrogen bond between the acetone and peroxyacetic acid molecules:

The high intensity of the band - higher than in nitromethane solution - indicates that a larger number of molecules are hydrogen-bonded. It is possible that it is for this reason that the rate of reaction in acetone is lower than in the other solvents. The addition of nitrobenzene does not affect the spectrum of a solution in toluene, a fact that indicates that no hydrogen bonding occurs between nitrobenzene and peroxyacetic acid. It is known that nitrobenzene, owing to its low basicity, does not form a strong hydrogen bond [8]. It should be noted that in nitrobenzene reaction proceeds at the same rate as in chloroform, toluene, and benzene, i.e., in the solvents that cannot be hydrogen-bonded to peroxyacetic acid on account of the absence of suitable structural groups. There can be no doubt that a hydrogen bond is formed between methanol and peroxyacetic acid, although we were unable to establish this directly.

Practically no work has been reported in the literature on the effect of solvents on the rate of oxidation by peroxy acids. Such data as exists, however, confirm our hypothesis concerning the effect of the hydrogen bond on the reaction. Meerwein and Bodendorf [9] studied the oxidation of propenylbenzene and anisaldehyde by peroxybenzoic acid. It was found that the rates of these two reactions were considerably lower in ether, acetone, and ethanol than in nitrobenzene, chloroform, benzene, carbon tetrachloride, and cyclohexane. It will be seen that, in this case also, reaction is slower in solvents that form hydrogen bonds than in those that are unable to form hydrogen bonds. Jorrisen and van der Beek [10, 11] found that only in an acetone solvent could they succeed in isolating peroxybenzoic acid formed by the autoxidation of benzaldehyde; in other solvents it disappeared instantaneously owing to rapid reaction with benzaldehyde. According to Kagan and Lyubarsky [12], the rate of the oxidation of acetaldehyde by peroxyacetic acid is almost the same in benzene, chloroform, nitrobenzene, and toluene (i.e., in the solvents that do not form hydrogen bonds with peroxyacetic acid).

Thus, on the basis of the results obtained by us and by other workers we may conclude that the presence of a hydrogen bond has a definite effect on the rate of oxidation of acetaldehyde by peroxyacetic acid (more exactly, on the rate of the first stage of this reaction). This explains the difference in the kinetics in different solvents: retardation of reaction is associated with the blocking effect of solvent molecules hydrogen-bonded to peroxyacetic acid molecules.

SUMMARY

It was shown that retardation of reaction found in some solvents is due to the blocking effect of solvent molecules hydrogen-bonded to peroxyacetic acid molecules. The presence of hydrogen bonds between peroxyacetic acid molecules and solvent molecules (nitromethane, acetone) was established by the determination of infrared absorption spectra.

KINETIC METHOD OF APPLYING LABELED ATOMS IN THE INVESTIGATION OF COMPLEX CHEMICAL AND BIOCHEMICAL PROCESSES

COMMUNICATION 6. RATES OF FORMATION AND TRANSFORMATION OF ACETALDEHYDE, CARBON MONOXIDE, AND CARBON DIOXIDE IN THE OXIDATION OF PROPENE

M. B. Neiman, V. Ya. Efremov, N. K. Serdyuk, and A. F. Lukovnikov

In spite of the large number of investigations that have been devoted to the oxidation of hydrocarbons, the mechanism of this complex process has not yet been adequately studied. No unified view has been established even with respect to the basic features of the mechanism. Thus, some authors consider that the substance causing degenerate branchings is a peroxy compound, and others that it is acetaldehyde. Some authors consider that acetaldehyde is simultaneously formed and consumed in the course of the reaction [1], and others consider that the consumption of acetaldehyde comes practically to a stop in the period when rapid oxidation of the hydrocarbon is occurring [2]. The question of the ways in which carbon oxides are formed and their rates of formation is also obscure. All of these questions have been investigated previously mainly by classical methods. As we considered that the kinetic method that we have developed could give some help in the elucidation of these matters, we have now investigated the oxidation of propene by this method.

As we were interested primarily in the behavior of acetaldehyde, we decided to carry out experiments on oxidation in a propene - oxygen mixture to which a small amount of $CH_3C^{14}HO$ was added. Some series of experiments were also carried out with additions of $C^{14}O$.

So that the kinetic method could be applied it was necessary first to develop a procedure for the determination of the acetaldehyde concentration in the oxidation products of propene, in which it was possible that some other aldehydes might be present. Also, it was necessary to determine whether hydrogen could be transferred from alcohols to acetaldehyde in accordance with the equation:

$$CH_3C^{14}HO + RCH_2OH \rightleftharpoons CH_3C^{14}H_2OH + RCHO.$$

It will be seen that transfer of hydrogen atoms between alcohol and aldehyde could result in the formation of labeled alcohol from labeled aldehyde, which, if the kinetic method were applied, would distort the results of radiochemical analysis.

EXPERIMENTAL

Synthesis of Reactants. Experimental Conditions. Propene was prepared by dehydration of isopropyl alcohol over a catalyst. It was carefully purified. Mass-spectrometric analysis showed that our product did not contain more than 0.3% of butenes.

Labeled carbon monoxide was prepared by catalytic exchange in the reaction:

$$CO + C^{14}O_2 \rightleftharpoons C^{14}O + CO_2$$

as described in the paper [3].

Acetaldehyde labeled with radioactive carbon in the carbonyl group was prepared as follows:

$$CH_3C^{14}OOH \xrightarrow[H_2SO_4]{C_2H_5OH} CH_3C^{14}OOC_2H_5 \xrightarrow{LiAlH_4} CH_3C^{14}H_2OH \xrightarrow[H_2SO_4]{K_2Cr_2O_7} CH_3C^{14}HO,$$

as described in the paper [4].

The experiments on the oxidation of propene were carried out in a glass vacuum apparatus. The volume of the reaction vessel was 205 ml, and its diameter was 4 cm.

For the investigation by the kinetic method we isolated carbon oxides and acetaldehyde from the oxidation products. The concentrations and specific activities of these products were determined by methods described previously [3, 5].

Determination of the Acetaldehyde Content. In order to apply the kinetic method it was necessary to know the acetaldehyde concentration, not the total concentration of aldehydes. Since the higher aldehydes are reduced at the same potential as acetaldehyde, it was necessary to establish whether the reaction products included any higher aldehydes and whether other oxygen-containing products present affected the height of the polarographic wave for acetaldehyde.

Fig. 1. Concentration of a standard acetaldehyde solution (o) and of a solution of the oxidation products of propene (v) as a function of the duration of passage of hydrogen (Curve 1); the same curve plotted in the coordinates log c and time (Curve 2)

Fig. 2. Variation in specific activity: 1 - CO_2; 2 - CO_2

It has been established previously that, when hydrogen is blown through an aqueous solution of a volatile compound, the concentration of the latter varies according to the law

$$x = x_0 e^{-kt} \qquad (1)$$

in which x is the concentration of the substance being blown out, x_0 is its initial concentration, t is the duration of blowing, and k is a constant. To a fairly close approximation, the constant k can be calculated from the formula:

$$k = \frac{Ap_0\alpha}{1244V}, \qquad (2)$$

in which A is the rate of blowing, p_0 is the vapor pressure of the substance investigated, V is the volume of the solution, and α is a coefficient characterizing the departure of the given solution from the ideal.

The value of k can be found also experimentally from the curve for the dependence of the concentration of the volatile compound on the duration of blowing with hydrogen. If we plot $x = f(t)$ [1] in the coordinates log x and t, k will be equal to the slope of the curve. For a complex mixture of compounds having various vapor pressures, the slope of the curve will vary and the value of k will be different.

It appeared to us, therefore, to be possible to decide whether any higher aldehydes were present in the mixture by comparison of the curves for the variation in concentration during the passage of hydrogen through a solution of pure acetaldehyde and through an actual mixture of the oxidation products of propene. Hydrogen was passed through an electrolytic vessel containing the solution of acetaldehyde or reaction products at a rate of 10.5 ml/minute at 22°. After a period of 20-60 minutes, blowing was discontinued and polarography was carried out in 0.1 N LiCl. The results of the experiments are presented in Fig. 1. The points corresponding to the acetaldehyde concentration in the solution of reaction products and in the standard acetaldehyde solution lie on a single curve. The coincidence of the curves indicates that higher aldehydes are substantially absent from the reaction products, and other oxygen-containing compounds do not affect the height of the polarographic wave for acetaldehyde. The same conclusion follows from a comparison of the values of the constant k calculated from Equation 2* and found from the slope of the straight line $\log x = f(t)$.

Study of the Possibility of Hydrogen Transfer in a Mixture of Alcohol and Acetaldehyde. In order to resolve this matter, an equimolecular mixture of CH_3CHO and $CH_3C^{14}H_2OH$ was heated in a glass vessel for several hours. The acetaldehyde was then analyzed radiochemically. Over the temperature range studied (315-387°) we did not detect any appreciable transfer of hydrogen from alcohol to acetaldehyde. The specific activity of acetaldehyde was about 3 conventional units irrespective of the duration of heating (the original specific activity of the alcohol was 500 units). It is possible that there was a slight amount of oxygen in the original mixture of alcohol and acetaldehyde, and this immediately oxidized $CH_3C^{14}H_2OH$ to $CH_3C^{14}HO$ and was then used up. When the mixture was heated further, the specific activity of the acetaldehyde did not change. In view of the minute extent, or even absence, of hydrogen transfer, we may neglect it.

Experimental Results

Oxidation of Propene in presence of $C^{14}O$ and CO_2. In order to establish the course of the process of CO_2 formation in the oxidation of propene and the proportion of it that is formed from CO, we carried out experiments on the oxidation of propene containing additions of $C^{14}O$ and CO_2. Oxidation was carried out in a mixture of 48% of C_3H_6, 50.7% of O_2, 1.08% of CO_2, and 0.22% of $C^{14}O$ at 340° and an initial pressure of 281 mm. The variation in the specific activities of CO and CO_2 in the course of the process is shown in Fig. 2. As can be seen from Fig. 2, the specific activity of carbon monoxide falls fairly rapidly, whereas that of carbon dioxide rises at first, passes through a maximum, and then falls off. If CO_2 were formed solely from CO, then at the maximum the specific activity curve for CO_2 would intersect the specific activity curve for CO. In our case the maximum α_{CO_2} lies considerably below the α_{CO} curve. This indicates that CO_2 is formed partially from CO, but mainly from other reaction products.

According to the equations for the kinetic method [3], the specific activities of CO and CO_2 and the rates of formation of CO_2 by parallel routes are related together at the point corresponding to maximum α_{CO_2}

* The value of $p_0\alpha$ was found from $p = p_0 x\alpha$, in which p is the partial vapor pressure of acetaldehyde in aqueous solution and x is its concentration. The dependence of p on x for acetaldehyde has been studied by Dobrinsky [7].

by the equation

$$\frac{w}{w_1} = \frac{a_{CO}}{a_{CO_2}}, \qquad (3)$$

in which w_1 is the rate of formation of CO_2 from carbon monoxide, and w is the overall rate of formation of CO_2 (by all routes).

It follows from our results that

$$\frac{a_{CO}}{a_{CO_2}} = 26.$$

This means that only 3-4% of carbon dioxide is formed by the oxidation of carbon monoxide. The bulk of it is formed in other ways.

These results are in accord with those obtained in an investigation of the behavior of CO and CO_2 in the butane oxidation [3], so that we may infer that there is a general mechanism for the formation of CO_2 which is common to the oxidation of saturated and unsaturated hydrocarbons.

Oxidation of Propene in presence of $CH_3C^{14}HO$. Experiments on the oxidation of propene in presence of $CH_3C^{14}HO$ was carried out with the mixture of 50% of O_2, 48.87% of C_3H_6, and 1.13% of $CH_3C^{14}HO$, the initial pressure being 243 mm and the temperature 315°. The kinetic curve, characterized by the occurrence of four cool flames, is shown in Fig. 3.

Fig. 3. Variation in pressure during the oxidation of propene (p_0 243 mm; temperature 315°)

The curves for the variation in concentration and specific activity of acetaldehyde are presented in Fig. 4. It should be noted that the fall in the specific activity of acetaldehyde with time does not correspond to the rise in its concentration; the latter changes much more rapidly than the former. Thus, before the cool flames occur, the concentration has grown by a factor of 3.8, whereas the specific activity has fallen by a factor of 5.5. After the extinction of the cool flames, the concentration increases by a factor of 5.5 and the specific activity falls by a factor of 19.5. This indicates that acetaldehyde is being consumed as well as formed.

Discussion of Experimental Results

From a knowledge of the way in which the concentration and specific activity of acetaldehyde vary, we may calculate the rates at which it is formed and consumed. It is known [8] that

$$-\frac{da}{dt} = \frac{aw}{x}, \qquad (4)$$

Fig. 4. Variation in concentration (Curve 1) and specific activity (Curve 2) of acetaldehyde (the shaded area corresponds to the cool-flame zone)

Fig. 5. Kinetics of the formation of acetaldehyde, no account being taken of its subsequent consumption (Curve 1). Curve 2 is constructed from Polyak and Shtern's data

in which α is the specific activity of acetaldehyde, w is the rate of its formation, and x is its concentration,

The amount of acetaldehyde formed at rate w in time t, its further oxidation not being taken into account, is

$$c = \int_0^t w\,dt. \qquad (5)$$

Substituting the value of w from Equations 4 and 5, we obtain

$$c = \int_{\alpha}^{\alpha_0} x\,d\ln\alpha. \qquad (6)$$

Fig. 6. Rates of formation (Curve 1) and consumption (Curve 2) of acetaldehyde in the cool-flame oxidation of propene

Having constructed the curve $x = f(\ln \alpha)$, we find c by graphical integration. The kinetics of the formation of acetaldehyde - its further oxidation not being taken into account - is shown in Fig. 5. In this figure we give also the analogous curve obtained by Polyak and Shtern [9] in work on the cool-flame oxidation of propene under identical conditions. A comparison of the courses of the curves shows that, when the cool-flame zone is passed, Polyak's results are almost identical with ours. As regards the period of induction, there are serious discrepancies. It is probable that substantial corrections must be made in the method of calculation used by these authors.

Knowing the actual kinetics of the accumulation of acetaldehyde, we may determine its rate of formation by graphical differentiation of the curve $c = f(t)$ (Fig. 5). The difference between the rates of formation and accumulation (the latter is found by graphical differentiation of Curve 1, Fig. 4) gives the rate of consumption. The rates so calculated are represented in Fig. 6, from which it will be seen that both formation and consumption occur throughout the whole course of the oxidation as far as the extinction of the cool flames. After the extinction of the cool flames the rate of formation of acetaldehyde falls almost to nil, although the rate of its consumption still remains appreciable.

Our conclusions are in conflict with those of Feklisov and Neiman [2] in their work on the behavior of acetaldehyde in the oxidation of butane.

Taking into account the fact that carbon dioxide is an end product of the oxidation and that carbon monoxide is not converted appreciably into dioxide, we calculated the rate of formation of these compounds from the carbonyl group of acetaldehyde and from other products. The rate of formation is found from the equation

$$w_1 = \frac{1}{\alpha_{CH_3CHO}} \frac{dI}{dt}, \qquad (7)$$

in which w_1 is the rate of formation of CO or CO_2 from acetaldehyde and $\frac{dI}{dt}$ is the rate of change of total activity of CO or CO_2. The rate of formation of CO and CO_2 by other routes (w_2) is the difference between the rate of accumulation w and the rate of formation from acetaldehyde:

$$w_2 = w - w_1. \qquad (8)$$

These rates were calculated from data obtained by analysis of the products before the formation of and after the extinction of the cool flames.

The results of the calculation are given in the table.

TABLE

Rates of Formation of CO and CO_2 from Acetaldehyde and other Oxidation Products

Duration of reaction (seconds)	Reaction product	Concentration (mmoles / liter)	Specific activity (microcuries / mmole) x 10^7	Total activity (microcurics) x 10^6	Rate of formation from $CH_3C^{14}HO$ (mmole / second)	Rate of formation from other products (mmole / second)
140	CO	0.1006	2.31	2.3	0.0041	0.013
160		0.4380	2.27	9.7		
140	CO_2	0.0394	15.7	6.2	0.002	0.002
160		0.1210	7.9	9.8		

The table shows that the rate of formation of CO from acetaldehyde in the cool-flame zone is only one-third of the rate of its formation by other routes. Carbon dioxide is formed from acetaldehyde and from other products at approximately equal rates. It follows from these considerations that, in the cool-flame zone, about one-half of the CO_2 and about 30% of the CO are formed from the carbonyl group of the acetaldehyde.

SUMMARY

1. It was shown by the blowing method that acetaldehyde can be determined polarographically in the products of the oxidation of propene.

2. It was shown that, at temperatures up to 387°, no hydrogen transfer occurs in alcohol-acetaldehyde mixtures.

3. It was shown that most of the carbon dioxide produced in the oxidation of propene is not formed by the oxidation of carbon monoxide.

4. It was shown that, in the oxidation of propene, acetaldehyde is formed and consumed at comparable rates.

5. It was shown that, in the cool-flame zone, about 50% of the carbon dioxide and 30% of the carbon monoxide are formed from the carbonyl group of acetaldehyde.

CRITERIA FOR CHAIN REACTIONS

V. V. Voevodsky

The main features distinguishing chain and radical processes from molecular processes are considered to be certain kinetic peculiarities, marked critical phenomena (in branched chain reactions), anomalously high quantum yields (in photochemical chain processes), appreciable acceleration or retardation when small additions are made, fundamental changes in kinetics when free radicals are added to the reacting system, etc. [1]. It must be noted that these criteria enable us to make a choice between chain, radical, and molecular mechanisms only when the relevant experiments give positive results. If, however, one or more chan- ne listed characteristics are absent, then it is generally not possible to affirm on this basis that a process is definitely a molecular one. It is often not less difficult to establish whether a reaction in which radicals take part is a chain reaction or simply a radical reaction.

An approach may be made to the solution of problems relating to the mechanism of a complex reaction on the basis of an analysis of the general problem of the concentrations of free radicals in the course of a chemical transformation. In fact, an examination of the usual chain reaction schemes - both for branched and for unbranched processes - leads to the conclusion that the high rates of such processes are associated with the formation, in the course of the reaction, of higher than equilibrium concentrations of free radicals (with respect to equilibrium with the original reactants). In purely radical thermal reactions, the concentrations of free radicals are always less than the equilibrium concentrations. On the other hand, in molecular reactions, in which the final products are formed without the participation of radicals, the concentrations of the latter always correspond to equilibrium with the original molecules.

It follows from these considerations that the most direct method of determining the character of a chemical process would be the exact measurement, in the given system, of the concentrations of those radicals which could result in the formation of the final products, and comparison of the values obtained with equilibrium values. Our experimental methods, however, permit us to measure absolute concentrations of radicals only in systems in which [R] attains a value of at least some hundredths of a millimeter (for example [H] and [OH] in rarefied flames of hydrogen and carbon monoxide [2]). When the value of [R] is appreciably less than this, as in such processes as the oxidation of hydrocarbons and unbranched chain reactions of halogenation, polymerization, thermal decomposition, etc., the direct does not appear to be possible. The exact determination of this ratio is rendered difficult also by the fact that absolute values of $[R]_{equil}$ can be calculated only very approximately for radicals that are at all complex: thermodynamic functions for such radicals are unknown, and the experimental determination of $[R]_{equil}$ is in most cases practically impossible. In spite of these difficulties, a choice between chain, radical, and molecular mechanisms may sometimes be made for processes which can be carried out reversibly under the conditions in which we are interested.

At the basis of the proposed method for the identification of the mechanism lies a quite obvious postulate, namely, that in an equilibrium system, the concentration of free radicals has its equilibrium value with respect to any of the reacting substances. Let us examine two reaction systems. In system (1) the reaction

$$A_1 + A_2 + \ldots \rightarrow B_1 + B_2 + \ldots \qquad (1)$$

proceeds with given concentrations of the starting substances (A_1), (A_2)... under given conditions. In system

(2), under the same external conditions, to the original substances at the initial concentrations (A_1), (A_2), etc., the final products are added in concentrations exactly corresponding to equilibrium conditions. It is quite obvious that no chemical reaction will be observed in system (2); for example, the concentration of A_1 will not change with time. However, since chemical equilibrium has a dynamic character, in such an equilibrium system two opposed processes - the consumption and formation of A_1 - will be constantly proceeding at equal rates.

Let us compare the concentrations of like radicals (or the total concentrations of radicals) in the two systems for different assumptions regarding the mechanism of the process. If it is a molecular reaction, then for any of the radicals:

$$[R_i]_I = [R_i]_{II} \quad \text{and} \quad (\Sigma_i[R_i])_I = (\Sigma_i[R_i])_{II}.$$

If it is a radical reaction, then at least for one of the radicals of the system,

$$[R_i]_I < [R_i]_{II} \quad \text{and} \quad (\Sigma_i[R_i])_I < (\Sigma_i[R_i])_{II}.$$

If it is a chain reaction, then at least for one radical, and sometimes for all,

$$[R_i]_I > [R_i]_{II} \quad \text{and} \quad (\Sigma_i[R_i])_I > (\Sigma_i[R_i])_{II}.$$

Hence, in order to establish the main features of the mechanism, there is no need to measure the absolute concentrations of free radicals. For this purpose it is quite sufficient to determine relative concentrations, and as a standard for comparison it is most convenient to select concentrations observed when the process is carried out under equilibrium conditions.

For the determination of relative concentrations of radicals, spectrum, magnetic-resonance, and mass-spectrometric methods can be used. We consider that in this way the question of the mechanism of the process - understood in the sense already indicated - can be solved unequivocally (only for reversible processes, of course).

Another approach to the solution of the question under consideration can be made by chemical methods; in particular, by the method of labeled atoms. Since the concentration of free radicals (in the case of chain and radical reactions) is unequivocally associated with the rate of the process, a comparison of the rate of reaction (1) in system I (w_I) with the rate of the transformation of the original reactants in the same direction in system II (w_{II}) should enable us to distinguish between the mechanisms in which we are interested. The greatest difficulty lies in the discovery of a method for the separate determination of the forward and reverse reactions in reversible processes. The only method available at present for the solution of this problem is the method of labeled atoms. If we label the molecules of one of the components of the original mixture (e.g. A_1), then by the rate at which A^*_1 is consumed (or the rate at which B^*_1 is formed) we may form an idea of the rate of the forward reaction in the equilibrium system II in a number of cases. We consider that this method may enable us to make a very clear distinction between chain reactions on the one hand and radical and molecular reactions on the other.

In the case of molecular processes the reaction rate depends, by definition, only on the concentrations of the original substances, and, since these concentrations are the same in both systems,

$$w_I = w_{II}.$$

in which w_{II} is the rate of reaction in system II measured with the aid of labeled atoms.

If the reaction (1) proceeds by a chain mechanism, then the rate at which the substance A is consumed can be written

$$-\frac{d[A_1]}{dt} = k[R_i][A_1].$$

in which k is the rate constant for the elementary process of interaction between the molecule A and the corresponding radical of the system (in this case R_1). Since in the equilibrium system II $[R_i]$ is less than in

system I,

$$w_I > w_{II}$$

In radical mechanisms $[R_i]$ is greater than $[R_i]_I$, and it would be expected that w_{II} would be greater than w_I.

This relationship holds, however, only in radical processes in which the molecule containing the labeled atom does not dissociate into radicals. For example, if we assume that the iodination of hydrogen has the radical mechanism recently proposed by Semenov [3]:

$$\left.\begin{aligned} M + I_2 &\underset{k_b}{\overset{k_a}{\rightleftarrows}} 2I + M \\ 2I + H_2 &\xrightarrow{k_c} 2HI \end{aligned}\right\} \quad (X)$$

and use deuterium or tritium as a labeled molecule, then it can be shown that the rate of consumption of H_2 under equilibrium conditions should be $(1 + k_c[H_2]/k_b[M])$ times as great as that obtaining when reaction is carried out in absence of HI. Such experiments might enable us to make a choice between the scheme given above and a molecular mechanism.

However, in radical reactions in which the labeled molecule takes part in the formation of radicals, for example:

$$A_1 + A_2 + \cdots \underset{k_b}{\overset{k_a}{\rightleftarrows}} R_1 + R_2 + \cdots \rightleftarrows B_1 + B_2 \cdots .$$

the rates w_I and w_{II} are found to be equal. This is explained by the fact that in such processes the values of w_I and w_{II} are not, strictly speaking, the rates of consumption of the original molecules, but are only differences between the rates of two reversible processes (a) and (b). Taking this circumstance into account, for radical reactions in general we find that

$$w_I \leq w_{II}.$$

The method of labeled atoms, therefore, is somewhat less versatile for the solution of our problem than any of the methods of determining relative concentrations of free radicals. It is, however, quite applicable as a criterion for chain mechanisms, which is a matter of great significance at the present time [3].

There are no data in the literature relating to the comparison of w_I and w_{II} in radical, chain, and molecular reactions. Similar considerations can be applied also in the analysis of data on the course of ionic and heterogeneous processes. In this connection we may mention the work of Wilson and Dickenson [4], in which data on the determination of w_{II} for the oxidation of arsenious acid labeled with radioactive arsenic to arsenic acid in presence of iodide ions were compared with the results of Roebuck and others [5], who studied the same reaction under conditions far removed from equilibrium. As direct exchange between the two acids did not occur under the conditions of these experiments - as was shown by special experiments - the authors' suggestion that the process proceeds by a dissociation-association ionic mechanism appears very probable. The reaction scheme proposed by Roebuck and others on the basis of kinetic data is based on the hypothesis that the determining stage is the reaction of the iodide ion (in the form I_3^-) with the undissociated arsenious acid molecule. Such a mechanism is quite analogous from the kinetic point of view to the radical mechanism discussed above. From our discussion it follows that in this case the rate of exchange in the equilibrium system (w_{II}) may be somewhat higher than the rate in a system in which the final product is absent (w_I). The numerical values of the effective constants given in the paper [4] are, respectively, 0.071 and 0.057 at 25° and 0.154 and 0.125 at 35°. It may therefore be considered that comparison of the values of w_I and w_{II} confirms the proposed mechanism.

SUMMARY

1. It is shown that molecular, chain, and radical reactions differ with respect to the concentrations of free radicals.

2. For the identification of chain reactions it is proposed that use should be made of the method of labeled atoms in order to compare the rates of the reaction A → B in absence of B and in presence of an equilibrium concentration of B.

POSSIBILITY OF THE DETONATION OF GAS MIXTURES IN CONICAL TUBES

S. M. Kogarko

In a previous paper we examined the possibility of initiating a spherical detonation wave in a space containing a gaseous mixture by means of an electric spark, an explosion, or the introduction of a shock wave. In the present paper we report the experimental results of a study of the detonation of gas mixtures in conical tubes and we make a theoretical examination of the conditions under which stable detonation is possible in a tube of constant section, in an infinite space, and in a conical tube.

Let us examine the conditions for the propagation of a stationary detonation wave in a tube of constant section.

It has been established experimentally that, in the propagation of a detonation wave in an explosive mixture contained in a tube of constant section, the wave velocity remains strictly constant over the whole length of the tube. In this case, the constancy of the velocity of the detonation wave is ensured by the constancy of the amplitude of the shock wave that is being propagated in the detonation wave front. On the basis of present-day concepts relating to the processes occurring in a detonation wave, the detonation of a gaseous explosive mixture can be described as follows. A powerful shock wave is propagated through the mixture at the detonation velocity, and this compresses the original mixture so that it attains a high pressure and is raised to a temperature of 1000-2000°. Behind the shock wave there moves a layer l of compressed mixture in which the period of induction for the self-ignition of the mixture τ begins and ends. The length of this layer of the mixture is $l \sim \tau(D - U)$, in which D is the detonation velocity and U is the mass velocity of the gas behind the shock wave. Moving behind the layer of compressed mixture is the reaction zone, in which the explosive chemical reaction is taking place. In this zone the chemical energy of the mixture is evolved and the composition of the mixture changes from its original state at the beginning of the zone to that of the reaction products at the end of the zone. This complex system, consisting of the shock wave, the layer of compressed but not yet reacting mixture, and the reaction zone, moving as a single unit at a constant velocity is the "detonation wave".

In the layer of the mixture compressed by the shock wave, in which the mixture stays during the induction period of self-ignition, no appreciable amount of the chemical energy of the mixture is given up. The compression of the original mixture occurs at the expense of the energy of the shock wave. Owing to the stationary nature of the detonation process, at any given moment the energy being expended by the shock wave in compressing the original mixture must be exactly counterbalanced by the energy entering the shock wave from the reaction zone. We shall assume that the energy expended by the shock wave in compressing the original mixture is proportional to the volume of the compressed mixture. For the detonation of a mixture in a cylindrical tube of constant cross section we may write the volumes of the original mixture that are compressed during two equal periods of time τ, from $t - \tau$ to t and from t to $t + \tau$, in the following form:

$$V_{(t-\tau),t} = \pi r^2 l' \quad \text{and} \quad V_{t,(t+\tau)} = \pi r^2 l',$$

in which l' is the distance traversed by the shock wave through the original mixture during the induction period τ, and r is the radius of the tube.

Let us now write down the ratio of the volume of the original mixture compressed by the shock wave during time τ beginning from the point of time $t - \tau$ to the volume of the original mixture compressed by

the shock wave for the same time τ but beginning from the point of time t. This ratio is the ratio of energies expended by the shock wave in the compression of the original mixture during two successive periods of time τ in the course of the whole process of detonation of the mixture; it will characterize the stability of the shock wave in the detonation process. Let us denote this ratio by H; for a tube of constant section it will be:

$$H = \frac{V_{(t-\tau),t}}{V_{t,(t+\tau)}} = \frac{\pi r^2 l'}{\pi r^2 l'} = 1 \qquad (1)$$

Hence, in the detonation of a gas mixture in a tube of constant section, the energy expended by the shock wave in compressing the original mixture for a period τ will be the same in any two such successive periods, i.e. constant, and therefore the amplitude of the shock wave will also remain constant during the whole detonation process, i.e. the propagation of the shock wave through the mixture will be a stationary process.

The loss of energy from the chemical reaction zone at the walls of the tube resulting from the thermal conductivity of the gas and the friction of the gas against the walls will remain constant during the detonation process and so cannot affect the stability of the detonation wave differently at different times during the detonation of a mixture in a tube of constant section. This loss results in some reduction in the detonation velocity. The experimentally measured detonation velocity is always a few percent below the value calculated from classical detonation theory. The extent of this loss depends on the length of the reaction zone in the detonation wave. This loss increases at the detonation limits, and it results in an appreciable reduction in the detonation velocity. However, before the difference between the theoretically calculated detonation velocity and the experimentally determined value becomes considerable and exceeds 10-15% of the detonation velocity, the limit is reached and the stationary propagation of detonation ceases [1, 2]. Here, we are particularly drawing attention to the fact that the detonation wave can undergo stationary propagation through the mixture when there are losses from the reaction zone corresponding to a reduction in detonation velocity by 10-15% of its theoretical value.

Propagation of a Spherical Detonation Wave

The propagation of a spherical detonation wave through a gaseous explosive mixture will differ fundamentally from the propagation of a detonation wave through a mixture confined in a tube of constant section. As the propagation of a spherical detonation wave proceeds, the surface of the shock wave will increase, and with increase in this surface, the period of induction for self-ignition of the mixture compressed by the spherical shock wave being constant, an increase will occur also in the volume of the original mixture that will be compressed by the spherical shock wave in the period τ. In any given short interval of time the spherical shock wave will always compress a greater amount of the original mixture than in the immediately preceding equal interval, but the spherical shock wave will be supported from the reaction zone by the chemical energy of a mixture compressed in a preceding interval of time; it follows that, in the propagation of a spherical detonation wave, there will always be some weakening of the shock wave. The weakening of the spherical shock wave arises from the lack of equality between the amounts of energy expended by the shock wave on the compression of the original mixture in two successive short intervals of time.

Let us examine what will happen with a spherical shock wave when the mixture is detonated in the center of a large space. At time t let the radius of a shock wave characterized by the same parameters as a plane shock wave formed by detonation of the same mixture in a tube of constant section have the value $r + 1/2\, l'$, in which l' is the length of the layer of original mixture compressed by the spherical shock wave during a time corresponding to the induction period τ for self-ignition of the mixture at the temperature and pressure corresponding to the given shock wave, and r is the average radius of the spherical shock wave for the interval of time from $t - \tau$ to t. The volume of the original mixture compressed by the spherical shock wave in the interval of time from $t - \tau$ to t will be determined by the following equation:

$$V_{(t-\tau),t} = 4\pi r^2 l' .$$

The volume of the original mixture compressed by the spherical shock wave in the interval of time from t to $t + \tau$ will be determined by the following equation:

$$V_{t,(t+\tau)} = 4\pi(\bar{r}+\bar{r}')^2\bar{r}.$$

Assuming, as we did previously, that the energy expended by the shock wave in compressing the original mixture is proportional to the amount of mixture compressed, we may evaluate indirectly the change in the amplitude of the spherical shock wave from one interval of time to the next from the amounts of energy expended by the shock wave in the compression of the original mixture in these two successive intervals of time. Let us write down the ratio of the volumes of the original mixture compressed by the spherical shock wave in the two successive intervals of time $t-\tau$ to t and t to $t+\tau$. This ratio will correspond to the ratio of the energies expended by the shock wave in compressing the original mixture for these two successive intervals of time. Denoting this ratio by H, we obtain

$$H = \frac{4\pi r^2 \bar{r}'}{4\pi \bar{r}'(\bar{r}+\bar{r}')^2} = \frac{r^2}{r^2+2r\bar{r}'+(\bar{r}')^2} = \frac{1}{1+2\frac{\bar{r}'}{r}+\left(\frac{\bar{r}'}{r}\right)^2}. \qquad (2)$$

For all positive values of $\bar{r}'$ and r this ratio will be less than unity. It follows quite obviously that a spherical shock wave will always expend more energy in one interval of time than in the preceding interval. Another, more important conclusion that can be drawn from an analysis of this expression is that the enfeeblement of a spherical shock wave in a mixture of constant period of induction for self-ignition will become less as the radius of the shock wave increases. A third conclusion is that, in different gaseous explosive mixtures having different periods of induction, the spherical shock wave will be enfeebled to the same extent in each mixture not when the radii r of the shock waves are the same, but for a constant value of $\bar{r}'/r$, which is proportional to the ratio that the induction period for self-ignition of the mixture compressed by the spherical shock wave bears to the radius of the shock wave, since $\bar{r}' = \tau D$ (D is the detonation velocity). Hence, when the enfeeblement of the spherical shock wave is still within the permissible limit, within which the breakdown of the spherical detonation wave does not yet occur, the initiation of spherical detonation waves in different gaseous explosive mixtures will be effected by spherical shock waves that will differ both in amplitude and extent.

Every gaseous explosive mixture will be characterized by a minimum critical spherical shock wave capable of initiating the spherical detonation of the mixture. In Fig. 1 the relationship between H, calculated from Equation 2, and $\log \bar{r}'/r$ is shown graphically.

Fig. 1: Dependence of the spherical shock wave on $\bar{r}'/r$.

When spherical detonation of the mixture occurs with some permissible enfeeblement of the spherical shock wave, in the course of the further propagation of the spherical detonation wave its stability should increase. Since the extent of the layer of mixture compressed by the shock wave remains constant in the detonation wave during the whole process of detonation and the radius of the spherical shock wave increases in proportion to the duration of the detonation, the ratio $\bar{r}'/r$ must diminish during the detonation process and the extent of the enfeeblement of the spherical shock wave must also diminish, as will be seen from Fig. 1. Since energy losses from the reaction zone of the detonation wave to the walls of the vessel are absent when spherical detonation of the mixture occurs, it would appear that a spherical detonation wave of high radius should be propagated with smaller losses than those occurring in a plane detonation wave in a tube of constant section, in which losses occur at the walls.

The enfeeblement of the spherical shock wave in the spherical detonation of a gaseous explosive mixture depends not only on the value of the period of induction for self-ignition τ, expressed as the length of the layer of original gas compressed by the shock wave but not yet undergoing reaction, but also on the ratio of the period

of induction to the radius of the spherical shock wave. Hence, in a gaseous explosive mixture for which the period of induction for self-ignition of the mixture compressed by the shock wave is τ and for which detonation is possible in a tube of constant section, it is possible to create a spherical shock wave of radius r such that the ratio l'/r will have less than the critical value. Hence, in a gaseous explosive mixture that is capable of detonation in a tube of constant section, spherical detonation can be initiated under certain experimental conditions.

Propagation of a Detonation Wave in a Conical Tube

From the considerations given above we concluded that, in the propagation of a detonation wave through a mixture in a tube of constant section, the shock wave always compresses the same amount of the original mixture in a given short interval of time τ throughout the whole detonation process. At any given time in the course of the process, the energy expended by the shock wave in compressing the original mixture is precisely counterbalanced by the energy entering the shock wave from the chemical-reaction zone of the detonation wave. What will happen with the shock wave that is propagated in the detonation wave front if we allow the detonation wave, which is undergoing stationary propagation through a mixture in a tube of constant section, to pass into a tube of variable section, i.e. a cone, filled with the same mixture?

Let us write down the ratio of the volume of the original mixture compressed by the shock wave in the time τ required for the detonation wave to move a distance l' along a tube of constant section to the volume of the original mixture compressed by the shock wave in the same interval of time τ when the detonation wave moves a distance l' in the cone. The volume of the original mixture compressed by the shock wave in time τ in the tube of constant section is $V_z = \pi r^2 l'$. The volume of the original mixture compressed by the shock wave in time τ in the cone is

$$V_k = \frac{1}{3}\pi l' [(r+a)^2 + r^2 + (r+a)r] = \pi l' \left(r^2 + ar + \frac{1}{3}a^2\right),$$

where

$$a = l' \tan \frac{1}{2}\alpha$$

α being the angle of the cone.

The ratio of the volumes is given by

$$H = \frac{V_z}{V_k} = \frac{\pi r^2 l'}{\pi l' \left(r^2 + ar + \frac{1}{3}a^2\right)} = \frac{1}{1 + \frac{a}{r} + \frac{1}{3}\left(\frac{a}{r}\right)^2} \qquad (3)$$

For all positive values of a and r, the value of this ratio will always be less than unity. Hence, when the detonation wave passes from a tube of constant section into a cone, the shock wave will be weakened. However, the extent to which it will be weakened may be made as small as we like by suitable choice of the values of a and r. The angle of the cone determines the extent to which the surface of the shock wave increases per unit length, i.e. the extent to which the shock wave is weakened. For every gaseous explosive mixture that is capable of undergoing detonation there is a permissible weakening of the shock wave such that further weakening makes stationary detonation of the mixture impossible; hence, the dimensions of the cone leading from a smaller to a larger tube are not immaterial for the determination of whether a detonation wave will pass from one tube to the other without being broken down.

Experimental Investigation of the Propagation of a Detonation Wave in a Conical Tube

For the investigation of the permissible weakening of the detonation wave the conical tube method was used. In this method, by varying the diameter of the entry tube and the angle of the cone we may vary the extent to which the wave is weakened within wide limits.

Fig. 2. Diagram of experimental arrangement

A diagram of the apparatus is given in Fig. 2. It consisted of a metal tube 1, 1200 mm in length, a glass tube 2 of the same internal diameter as the metal tube, a metal cone 3, a wide glass tube 4, one end of which was closed by the rubber stopper 5, a recording camera 6 with its objective 7, and connecting tubes for removing reaction products from the apparatus and for filling it with the gaseous explosive mixture under investigation. One end of the metal tube 1 was soldered into the cap 8, which contained the spark plug 9. The metal tube 1 at its open end, the glass tube 2, the metal cone 3, and the wide glass tube 4 were all firmly fixed together at their end surfaces with the aid of short pieces of rubber tubing 10. The part of the apparatus that was filled with the explosive mixture and was shattered in the experiment was separated from the camera by the shield 11, in which a 10-mm slit was made to permit the photoregistration of the propagation of flame in the glass part of the apparatus. The ignition of the mixture was carried out in the metal cap, either by burning a fine copper wire fixed to the electrodes of the spark plug, or, in mixtures highly diluted with nitrogen, by exploding a small amount of lead azide.

The following results were obtained. In the mixture $2H_2 + O_2$, the detonation wave progressed along a tube of internal diameter 5 mm and passed without being broken down through a 5 mm/35 mm cone of angle $\alpha = 11° 30'$ into a tube of internal diameter 35 mm. When the angle of the cone was increased to 23° 0', the detonation wave broke down in a 5 mm/35 mm cone. When the diameter of the first cylindrical tube was increased from 5 to 8 mm, the detonation wave in the $2H_2 + O_2$ mixture passed an 8 mm/38 mm cone of angle $\alpha = 23° 0'$ without breakdown, but was broken down in an 8 mm/38 mm cone of angle $\alpha = 33° 30'$.

Two photorecordings of the propagation of flame fronts through glass tubes placed before and after a cone are shown in Figures 3A and 3B. The photorecordings correspond to the movement of the flame front from top to bottom and the movement of the film from left to right. The upper white band corresponds to the propagation of the flame front and the incandescence of the reaction products in the narrow glass tube placed before the cone, and the lower white band corresponds to the propagation of the flame front and the incandescence of the reaction products in the wide glass tube placed after the cone. The black band sandwiched between the white bands corresponds to the length of the metal cone, in which the flame front is not photographed.

Photorecording 3A corresponds to the propagation of a detonation wave through the mixture $2H_2 + O_2$ in a glass tube of internal diameter 8 mm, followed by an 8 mm/38 mm metal cone of angle $\alpha = 23° 0'$ and a glass tube of internal diameter 38 mm. As can be seen from the photorecording, the detonation wave front is propagated with the same strictly constant velocity both in the 8-mm glass tube and also in the 38-mm glass tube that follows the cone. Detonation velocity in glass tubes was 2790 m per second; average value in cone was 2660 m/sec. Detonation wave propagation rate is reduced in the cone, but the wave is not broken down. Photorecord-

Fig. 3A. Propagation of a detonation wave in glass tubes situated before and after a cone

Fig. 3B. Propagation of a detonation wave in glass tubes situated before and after a cone

ing 3B corresponds to a) the propagation of the detonation wave front through the mixture $2H_2 + O_2$ in a glass tube of internal diameter 8 mm; b) the breakdown of the detonation wave in an 8 mm/38 mm cone of angle $\alpha = 33° 30'$; and c) the rapid burning of the mixture in a glass tube of internal diameter 38 mm. It will be clearly seen from the photorecording that the detonation wave is broken down in the cone. The detonation velocity in the 8-mm glass tube was 2760 m per second, and the average velocity of the flame front in the cone was 950 m per second.

The table gives the results of experiments on other mixtures. The pairs of cylindrical glass tubes used in these experiments had diameters of 5 and 35 mm, 8 and 38 mm, and 10 and 40 mm, and the end diameters of the metal cones were 5 mm/35 mm, 8 mm/38 mm, and 10 mm/40 mm.

TABLE

Dimensions of Conical Tubes	5 mm/35 mm		8 mm/38 mm			10 mm/40 mm	
Composition of Mixture	Angle of Cone						
	11°30'	23°0'	23°0'	33°0'	44°0'	11°30'	23°0'

Discussion of Experimental Results

The possibility of the spherical detonation of a gas mixture has been examined from the point of view taken by the modern theory of detonation in its treatment of the mechanism of the chemical reaction occurring in a detonation wave produced in a gaseous explosive mixture. The enfeeblement of the spherical shock wave depends both on the size of the spherical detonation wave and on the characteristics of the investigated mixture with respect to reaction kinetics. For a given size of spherical detonation wave the weakening of the spherical shock wave will be the greater, the longer the period of induction for self-ignition of the investigated mixture under the conditions of its compression by the spherical shock wave. When the radius of the spherical detonation wave is sufficiently large, the weakening of the spherical shock wave may, owing to the absence of losses from the reaction zone to the walls of the vessel, be made equal to or less than the weakening of a plane shock wave in the detonation of a mixture in a tube of constant section. It follows from this theoretical result that the spherical detonation of a gaseous explosive mixture is possible.

The weakening of a spherical shock wave depends on the characteristics of the investigated mixture with respect to reaction kinetics and, if it is assumed that the propagation of a stable spherical detonation wave through a mixture becomes possible only when the extent to which the spherical shock wave is weakened is less than a certain critical value that is identical for all gas mixtures (P'/r being constant for any gas mixture), then the critical radius of the spherical shock wave necessary for the initiation of the spherical detonation of the investigated mixture will be the greater, the greater the period of induction for self-ignition of the mixture under the conditions of its compression by the spherical shock wave. It follows that in the experimental determination of the possibility of the spherical detonation of various gaseous explosive mixtures it is impossible to use only one size of spherical shock wave for the initiation. The lack of success that investigators have had in their attempts to initiate spherical detonation in gaseous explosive mixtures is to be explained by the fact that at the time when these experiments were carried out no clear concepts existed concerning the processes occurring in a detonation wave, with the result that the experiments were incorrectly designed. In the experiments of Laffitte [3], attempts were made to bring about the spherical detonation of various gaseous explosive mixtures by the introduction of the plane detonation wave into the investigated mixture from a tube which was of the same dia-

meter in all experiments.

In the investigation of the propagation of a detonation wave through a gaseous explosive mixture contained in a tube of variable section (a cone), it was shown that the detonation wave remains stable when its velocity falls to about 85% of the detonation velocity of the same mixture in a tube of constant section. It is particularly important to note that a plane detonation wave can undergo stable propagation through a mixture not only in a tube of constant section, but also in a tube of variable section so long as the change in the area of the shock wave (due to the change in the cross-sectional area of the tube) produces a weakening in this wave that is within the permissible limit for the given mixture. It follows from these considerations and from the experimental results that we can deliberately change the area of a detonation wave from a small value to any large value that we care to stipulate without destroying the stability of the detonation wave.

SUMMARY

1. It is shown that, in any gaseous explosive mixture capable of being detonated in a tube of constant section, it is possible also to initiate the stationary propagation of a spherical detonation wave.

2. For the initiation of spherical detonation, the critical radius that the spherical shock wave must have will be the greater, the longer the period of induction for self-ignition of the mixture under the conditions of its compression by the spherical shock wave.

3. The relationship derived theoretically between the weakening of the shock wave, on the one hand, and the characteristics of the investigated mixture with respect to reaction kinetics, the geometric dimensions of the wave, and the parameters of the apparatus, on the other, is qualitatively in close accord with experiment.

PROPERTIES OF ATOMS AT SUPERHIGH PRESSURES

A. F. Kapustinsky

It is difficult to name any law or system in the field of chemistry that is comparable in importance, in wideness of scope, and in the variety of its applications with the periodic law and system of chemical elements proposed by Mendeleev in 1869. All that appeared to be inconsistent with this great generalization was gradually removed as knowledge progressed, whereas all of its consequences received support from experiment, which demonstrated not only the truth of the law, but also its power as a working tool that enables the chemist to predict new facts.

Among the various properties of the elements coming within the scope of the periodic law, from the very beginning the most fundamental were, of course, their chemical properties. However, owing to the various relationships existing between the properties of natural bodies, many physicochemical and even purely physical properties - not only of atoms, but also of molecules and crystals - have been found to be subject in one way or another to the Mendeleev law.

We may draw also chemical thermodynamics into the discussion of this problem, for in this field chemistry is again the principal object of attention, and loss of free energy is a true measure of chemical affinity. Free energy, however, stands in a definite relationship to two other functions of state - enthalpy and entropy. The first of these, known to chemists in the form of the heat of chemical reaction, was the first to be investigated. First Lowry in 1882 and later Mendeleev himself [1] established a periodicity in the heats of formation of chemical compounds; and comparatively recently we have succeeded in establishing a simple, rough thermodynamic logarithmic law [2] which enables the relationship between heats of reaction and the main characteristics of the atoms in the Mendeleev system to be expressed in mathematical form. Still earlier - in 1945 - we discovered the periodicity of ionic and absolute entropies [3], which is interesting in that entropy is the only thermodynamic function of state of which the absolute value is known. We cite here only a few examples that have a certain bearing on the further discussion, but it would be possible to give a very long list of the varied and fruitful applications of the periodic law.

Does this mean that this law (and also the system that is derived from it), in the truth of which there can be no doubt, is some kind of absolute, unconditional fetish that is true everywhere, always, and under all possible circumstances? There are no such absolute laws in chemistry, just as there can be no limit to our knowledge of matter. Like all natural laws, the Mendeleev law has quite definite limitations to its applicability; outside these limits it is no longer applicable. One of our tasks in this short communication is to establish, qualitatively and quantitatively, these limits of applicability.

For this we must first of all remind ourselves of the general line of Mendeleev's discovery: the periodicity of the dependence of the chemical properties of the atoms on one of their physical characteristics, namely on their atomic weights or, more accurately, atomic numbers. The development of this general line led to very fruitful interaction between investigations on the electronic theory of the structure of matter and investigations on the periodic law, and the result was the creation of the electronic theory of atomic structure and of the chemical bond. The periodic system of the elements given below (Fig. 1), which was first proposed by Mendeleev, developed further by Bohr and Thomsen, and somewhat modified by various workers including us [4], expresses the natural classification of atoms according to the structures of their electron envelopes.

It will not be an exaggeration to assert that where there is chemistry there is the periodic law, and where there is Mendeleev periodicity there is also a periodicity in the electronic environments of the atomic nuclei.

Fig. 1. Stepwise form of the Mendeleev periodic system of the chemical elements.

It follows that for atoms which for some cause or other have lost their correct electronic entourage, the Mendeleev periodic law will not be applicable.

Although this assertion can be regarded as indisputable, if it is not subjected to special examination and investigation it nevertheless remains as nothing more than a mere declaration. It is not difficult to establish the direction that a theoretical investigation must take: it arises quite naturally in the study of the atomic envelopes from the point of view of the Pauli exclusion principle. As is well known, the source of the individuality that is so characteristic of the Mendeleev system is expressed by this principle, which asserts the impossibility for any two electrons in the same atom to have their four quantum numbers identical.

It is well known also, however, that the Pauli principle is not sufficient for the derivation of the periodic law and system. It is necessary to have recourse to the concept of uncompleted electron shells in atoms, as an example of which we may take calcium, for which it is found that it is energetically more favorable for the two outer electrons to go into the fourth energy level, in spite of the possibility in principle for them to go into the third level, which is not yet completed (Table 1).

It appears to be quite possible to transfer these two electrons by external action into the lower orbital 3d. In order to do this it is necessary to apply pressure sufficient to compress the electron envelopes. The electrons will then pass to an orbital that is closer to the nucleus without in any way acting contrary to the Pauli principle. Here an important and interesting question arises: will this treatment alter the chemical nature of calcium as an element? Undoubtedly yes, for its electronic structure will become quite different, as will be seen clearly from Table 2.

Table 1

	1s	2s	2p	3s	3p	3d	4s
Ca_{20}	2	2	6	2	6	—	2

Table 2

$\overline{Fe}_{26}$	2	2	6	2	6	8	—
Ni^{++}	2	2	6	2	6	8	—

After the above-described transformation of the atom, its nucleus will remain unaffected - a fact, however, that is irrelevant, since the nucleus takes no part in chemical processes. The number of electrons also remains unchanged. The chemical characteristics will change, however, because both the electron orbitals and the energy of the electrons have changed. For the same electronic "composition", the arrangement of the electrons in space has become different - we meet the phenomenon of electronic isomerism of atoms. We shall refer to the isomer of the calcium atom as "isocalcium" and denote it by $\overline{Ca}$; it already has different, what might be called degenerate, chemical properties. This difference in properties arises from a difference in structure: the localization of the outer electrons in the fourth shell previously resulted in the appearance of the element in the fourth period of the system, whereas the electrons do not now extend beyond the third shell, so that the element must appear in the third period of the system. "Isocalcium" may now be regarded more as an analog of a known titanium ion, as can be seen from Table 2.

Fig. 2. Diagrammatic representation of the alternation of even and odd periods in the Mendeleev system.

The iron atom provides another curious example of atomic isomerism. In Table 3 we present the normal iron atom, its electronic isomer "isoiron", and its "partial" isomer (only electronic isomerism is present, the nuclear charges being different) or analog of "isoiron" - the ordinary nickel ion.

The electronic isomerization of atoms under pressure is therefore able to alter their chemical properties substantially, for their chemistry is determined by the electronic structure of the outer shells; this is what we have called the degeneration of the chemical properties of the atoms. This peculiar forcing of the electrons into lower, incomplete shells without violation of the exclusion principle - which is possible for elements standing after neon, i.e. beginning from the third period - has, of course, a radical effect both on the properties of the element and, therefore, on its position in the periodic system.

Whereas the well known form of the Mendeleev system with its alternating pairs of even and odd periods and its atoms with incomplete inner shells is divided into seven periods (Fig. 2), the new system of "degener-

ate" atoms must have a much simpler appearance and will contain only five periods instead of seven. At what pressures can such transformations of atoms be brought about? With the aid of the quantum theory of metals developed by Wigner and Seitz Sternheimer [5] calculated the work required for the transfer of an electron from the 6f to the 5d level in the cesium atom. We recalculated his results in terms of pressure and obtained a value of 45,000 atm. Such a pressure is quite realizable, even under laboratory conditions. It is true that for cesium, which has a high atomic radius, this work has its least value; for other atoms it may be 2-3 times as great. Nevertheless, this and other investigations show that for pressures of the order of 50,000-120,000 atm upwards electronic isomerization is quite possible.

Fig. 3. Diagram of a periodic system containing atoms having degenerate chemical properties (cross-shading).

Fig. 4. Diagram of "periodicity function" at various pressures. The values of the "periodicity function" at various pressures are represented by the arrows at the right of the diagram.

The periodic system of chemical elements corresponding to these thermodynamic conditions is still completely consistent with the Pauli principle. The atoms do not contain "vacant" or incomplete quantum levels. The boundaries of these periods (not counting the zero period) will, as before, lie at helium and neon in the first and second periods, which will preserve their normal structures, and then - in the periods corresponding to elements having "degenerate" chemical properties - they will lie at nickel in the third period and at neodymium in the fourth (Fig. 3).

We shall now try to make an approach to the question of the realizability of still deeper transformations in atomic structure, resulting no longer in changes in the chemistry of the elements, but in the complete disappearance of chemistry.

A rigorous solution of the question is again impossible, and existing data enable us to make only very crude approximations in our approach. Even here, however, this approach can be checked - by quantum-mechanical calculations (for example, Ramsey's calculations for hydrogen) and, as we shall see below, by comparison with seismometric data. As usual in geochemistry, we shall use graphs in which pressures are represented on a logarithmic scale, which is always convenient when operating with high numbers; for us, the essential matter is only the obtaining of a more or less smooth curve passing through all points and the plotting of the corresponding seismological data on the same graph - the equation of the curve is immaterial.

In order to answer this question it is necessary to examine the relationship between the periodic changes of various properties and pressure. Unfortunately, our choice of properties is at present extremely limited; there is adequate information on only one property, namely, compressibility.

Richards established periodicity in the relationship between the compressibility of the elements and atomic weight. On the basis of Bridgman's data for 30,000 and 100,000 atm, Vereshchagin and Likhter [6] showed that this periodicity persists up to these high pressures, although it becomes progressively less distinct. This can be best seen from Fig. 4, in which from top to bottom - from low pressures to high - the reduction in the range of the periodicity in the relationship between this property and atomic number is represented in crude diagrammatic fashion. Let us introduce the periodicity function f(P), this being the distance (the arrow on the right in Fig. 4) between the broken lines marking the limits of the variations observed; it may be said to give the "sweep" of the periodic variations. It is clear that the lower the value of this function, the less marked is the periodicity, and its attainment of the value zero corresponds to the complete disappearance of periodicity.

TABLE 4

Pressure p (atm)	Periodicity function f(P)	Logarithm of pressure(log p)	Depth h (km)
1	2.5	0.00	–
30,000	1.3	4.48	–
100,000	0.9	5.00	–
(1,400,000)	0.0	(6.15)	(2,900)

Fig. 5. Graph of the change of the periodicity function with pressure.

Table 4 gives the periodicity function, which we have calculated from Vereshchagin and Likhter's data, in its dependence on pressure, expressed, as already stated, as log p (Fig. 5). We give also the depth below the earth's surface corresponding to a given pressure. Although it is highly probable that a somewhat different picture will be obtained for some property other than compressibility, there is no reason to suppose that the difference will be very great, and the data that we already have may therefore be used in the formulation of certain generalizations.

In Fig. 5 points representing the tabular data lie on a smooth curve, which passes through a point for which the periodicity function has zero value at a pressure of approximately 1,400,000 atm (log p = 6.15). Although this is a very rough extrapolation, in which there may be an error of as much as 100,000 atm, the value will be of the right order. At such pressures, therefore, all chemical properties of matter disappear, the regular layered arrangement of electrons around the atomic nucleus disappears, and we are left merely with "impersonal" nuclei immersed in a general electronic plasma - a universal metallic state of matter.

Can we find any experimental support - if not direct, then at least indirect - of the correctness, with respect to order of magnitude, of our estimates of the quantities under consideration? An answer is found in seismological data.

A study of the passage of seismic waves [7] in different directions through the earth indicates definitely the existence of two important thresholds in the state of matter: a rather diffuse one at a depth of about 100 km corresponding to the thickness of the earth's crust (the so-called Mokhorovichich surface), and another at a depth of 2900 km. The pressure at the first depth ranges from 50,000-100,000 atm, and at the second it is about 1,400,000 atm, in close accord with the estimates that we made by a method quite independent of geophysical and geochemical methods. Inasmuch as homogeneity of phase (more accurately, aggregate invariability) throughout the whole depth of the earth is no longer a matter of doubt, it is difficult to regard this agreement

Fig. 6. Zones of the earth: 1) zone of normal chemistry; 2) zone of degenerate chemistry; 3) zone of zero chemistry

otherwise than as confirmation of our estimates of the pressures at which sharp changes occur in the electronic structure of matter. Moreover, from this result we can draw conclusions that are of great importance for geochemistry. It is evident that, in the earth's crust down to a depth of about 100 km, chemical reactions proceed in accordance with the laws we know and the elements follow Mendeleev's periodic system. We have here the geosphere, which may be called the zone of normal chemistry. At greater depths, down to the beginning of the core or centrisphere, pressures are such that the electronic envelopes of the atoms are forced inward to the maximum extent and the properties of the atom are degenerate; this is the zone of degenerate chemistry in which the Mendeleev law in its usual form is already untrue. Finally, there is the core of centrisphere of the earth - the zone of zero chemistry, in which the pressure is so high that no manifestations of chemical properties occur and the periodic system of the elements loses all meaning; only nuclear periodicity is possible. This "geochemical model" of the earth, which is represented in Fig. 6, is in full accord with purely geological concepts of a crust, eclogitic geosphere, and core having boundaries characterized by the same pressures and depths; it therefore complements the geological picture from the viewpoint of chemistry.

Such, therefore, are the effects of high and superhigh pressures on the properties of atoms. In this way, from purely theoretical considerations, we can predict the electronic isomerization of atoms with consequent radical changes in their chemical properties and therefore in the whole structure of Mendeleev's periodic system of elements; and we can predict also the complete annihilation of chemistry, corresponding to complete breakdown in the functioning of the Mendeleev periodic law for the atoms of the elements. These considerations, taken in conjunction with a consideration of the increase in pressure with increase of depth below the earth's surface, enables us to divide the earth into three geospheres - the geospheres of normal, degenerate, and zero chemistry.

This is not all, however; for without confining ourselves to the qualitative side of the solution of the problem, we can now envisage a quantitative approach that will render our solution more precise. Our extremely tentative estimates of the effect of pressure on the structure of electron envelopes correspond in order of magnitude with seismological and geological estimates of the pressures characteristic of the boundaries of these depth zones of our planet - the boundaries of the crust and of the core or centrisphere. In this way we can envisage the possibility of a more or less quantitative estimate of the probable limits of applicability of the Mendeleev periodic law of the elements in nature.

Like every other rigorous and rational limitation of the applicability of a scientific generalization, this one can only consolidate and further confirm this extremely important law of chemistry.

SUMMARY

As the atoms of the elements are compressed under pressures rising to superhigh values, a) at first electrons pass into unfilled levels permitted by the Pauli exclusion principle, with the result that "degeneration" of the normal chemical properties of the atoms occurs and the whole structure of the periodic system of elements changes its form, and b) the "crushing" of the electronic envelopes then occurs with delocalization of electrons, complete loss of the chemical distinctions between the particles, and formation of a universal metallic state of matter.

The paper examines the thermodynamics, quantum-chemical, and seismological data that support the above-stated views, and a hypothesis is advanced concerning the zonal structure of the interior of the earth and the physicochemical properties of the geochemical shells.

DECOMPOSITION AND FORMATION OF ONIUM SALTS, AND THE SYNTHESIS OF HETEROORGANIC COMPOUNDS

COMMUNICATION 9. HETEROLYTIC DECOMPOSITION OF BENZENEDIAZONIUM FLUOSILICATE

L. G. Makarova and M. K. Matveeva

In previous investigations one of us in collaboration with Nesmeyanov has demonstrated the heterolytic character of the decomposition of benzenediazonium fluoborate in reactions of oriented substitution in the benzene ring [1], in reactions with unsaturated polar compounds [2], and in reactions with nitriles [3]. It may be assumed that benzenediazonium fluosilicate will also decompose heterolytically:

$$(C_6H_5|:N_2)_2|:SiF_6 \longrightarrow 2C_6H_5^+ + N_2 + SiF_6^{--},$$

and this view is supported by the formation of fluoroarenes by the thermal decomposition of arenediazonium fluosilicates [4], which is analogous to Balz and Schiemann's synthesis of fluoroarenes from arenediazonium fluoborates [5]. Moreover, as in the case of arenediazonium fluoborates, the low probability of the formation of a fluorine atom makes a homolytic type of decomposition unlikely.

As in the case of benzenediazonium fluoborates, reactions of oriented substitution in the benzene ring and reactions with nitriles can be applied to the demonstration of the heterolytic character of the decomposition of benzenediazonium fluosilicate. If benzenediazonium fluosilicate undergoes heterolytic decomposition, the phenyl cation formed, being an electrophilic reagent, should substitute in the meta position in a benzene ring containing a meta-orienting substituent, and also, when decomposition occurs in an aromatic nitrile, the phenyl cation may add at the point of highest electron density in the nitrile molecule - at the nitrogen of the nitrile group.

We carried out the decomposition of benzenediazonium fluosilicate in substituted benzenes containing an orienting group of the second kind - in nitrobenzene, methyl and ethyl benzoates, acetophenone, benzonitrile, and phenylacetonitrile. When the decomposition of benzenediazonium fluosilicate was brought about in nitrobenzene, the phenyl cation formed entered the meta position with formation of 3-nitrobiphenyl. Decomposition in ethyl and methyl benzoates yielded 3-biphenylcarboxylic acid after hydrolysis. Phenyl entered not only the meta position with respect to the alkoxycarbonyl group, but also, to a slight extent, the para position, the meta and para isomers being formed in the proportions of about 10 : 1 (for both ethyl and methyl benzoates). The formation of a little para isomer as well as meta is not surprising, for it is known that the alkoxycarbonyl group is only a moderately powerful meta-directing group. When the decomposition took place in benzoic esters, transesterification also occurred with formation of phenyl benzoate, which we interpret as the result of the action of the phenyl cation on the alkoxycarbonyl group.

As in the case of benzenediazonium fluoborate, in the decomposition of benzenediazonium fluosilicate in nitrile media the phenyl cation added to the nitrogen of the nitrile group and anilides of the corresponding acids were obtained when the products were treated with water. When the decomposition was carried out in phenylacetonitrile, 2-phenylacetanilide was obtained in 36% yield, and decomposition in benzonitrile gave benzanilide in 28% yield. Like the decomposition of benzenediazonium fluoborate in nitriles and unlike that of homolytically decomposing diazo compounds [6], the decomposition of benzenediazonium fluosilicate in

nitriles was not accompanied by the formation of ketones or the entry of phenyl into the benzene ring. The formation of nitrile trimers, which arise during the decomposition of benzenediazonium fluoborate in nitriles probably as a result of the polymerizing action of boron trifluoride, was not observed in the decomposition of benzenediazonium fluosilicate in nitriles.

The products of the decomposition of benzenediazonium fluosilicate in acetophenone were the same as those obtained from benzenediazonium fluoborate in the same medium and were different from the products of the decomposition of homolytically decomposing diazo compounds in acetophenone. During the decomposition of benzenediazonium fluosilicate in acetophenone, the phenyl cation entered the benzene ring of the acetophenone. The phenyl cation entered mainly the position meta to the acetyl group, as was shown by the conversion of the corresponding fraction into 3-biphenylcarboxylic acid by the haloform reaction. To a less extent phenyl entered also the para position, and 4'-phenylacetophenone was isolated. The meta and para isomers were obtained in the proportions of 4 : 1. It is again necessary to take the comparative feebleness of the meta-orienting power of the acetyl group into account. In the decomposition of the homolytically decomposing diazo compound potassium phenylazoformate in acetophenone [7] phenyl did not enter the benzene ring, the reaction product being the dimer of the $\cdot CH_2COC_3H_5$ radical, 1,4-diphenyl-1,4-butanedione.

Thus, phenyl formed in the decomposition of benzenediazonium fluosilicate attacks the nitrile molecule at the point of highest electron density - the nitrogen of the nitrile group - and the meta position in a benzene ring containing a meta-orienting substituent (the alkoxyacarbonyl group of a benzoic ester), which indicates the cationoid character of this phenyl and the heterolytic type of decomposition of the diazonium salt that generates it.

EXPERIMENTAL

Decomposition of Benzenediazonium Fluosilicate

The reaction was carried out in a four-necked flask fitted with oil-sealed stirrer, reflux condenser, and thermometer. The fourth neck served for the introduction of the diazonium salt.

a) Decomposition of Nitrobenzene. Over a period of two hours 49 g of benzenediazonium fluosilicate was added in small portions to 150 g of nitrobenzene at 75°. The reaction mixture became dark-colored, the temperature rose slightly, and faint fumes were observed. When the addition of fluosilicate was complete, the temperature was raised to 80° and the reaction mixture frothed slightly for a short time. The mixture was stirred at 79-80° for 45 minutes. On the next day benzene was poured onto the thick dark-colored reaction mixture and a tar separated, which was washed many times with benzene. The benzene extracts were washed with 10% caustic soda (some more resin separated and was filtered off) and with water. They were dried over sodium sulfate, and benzene and nitrobenzene were distilled off, the latter under reduced pressure. Distillation of the residue gave 2.5 g of product, m.p. 150-164 (7 mm). This substance crystallized out completely and, after crystallization from methanol, its melting point and the melting point of a mixture with known 3-nitrobiphenyl were 60°.

b) Decomposition in Methyl Benzoate. The diazonium salt (33 g) was added over a period of 45 minutes to 116 g of methyl benzoate at 105°. Decomposition began immediately with evolution of white fumes. When addition was complete, the mixture was maintained at 150° for one hour. On the next day the reaction mixture was dissolved in ether, and the ether solution was washed with 10% caustic soda and then water. The solution was dried over sodium sulfate, ether was distilled off, and the residue was vacuum-distilled. The following fractions were obtained: Fraction I, b.p. up to 90° (4 mm) (methyl benzoate); Fraction II, 2.48 g, b.p. 125-150°, a liquid; Fraction III, 0.9 g, b.p. 150-165°, which partially crystallized out. Fraction II was hydrolyzed at the boil with 20 ml of 20% aqueous caustic soda for ten hours, some drops of unsaponified oil were extracted with ether, the alkaline layer was acidified with 15% sulfuric acid, excess of concentrated sodium carbonate solution was added, and the mixture was steam-distilled. The distillate gave a feeble reaction for phenol with ferric chloride and bromine water. The alkaline solution was acidified with sulfuric acid, and the precipitate that formed was crystallized from ethanol. The yield was 0.8 g, and the melting points of the product and of a mixture of the product with known 3-biphenylcarboxylic acid were identical (164°).

The precipitate that formed in Fraction III was crystallized from ethanol, and it then melted, both alone

and in mixture with known methyl 4-biphenylcarboxylate, at 117°. The filtrate from Fraction III was hydrolyzed and further treated under the conditions used for Fraction II. A feeble reaction was obtained for phenol in the distillate obtained from the sodium carbonate solution. The residue in the distillation flask was diluted with water, and the undissolved residue was filtered off and boiled with concentrated hydrochloric acid for 15-20 minutes. The precipitate formed was recrystallized from ethanol and then amounted to 0.05 g. Its melting point and the melting point of a mixture of the product with known 4-biphenylcarboxylic acid were identical (222°).

c) Decomposition in Ethyl Benzoate. The diazonium salt (38 g) was added over a period of 40 minutes to 130 g of ethyl benzoate at 105°. Bubbles of gas and white fumes were evolved. When addition was complete, the mixture was stirred at 110° for one hour. It was then dissolved in ether, and the ether solution was washed with 10% caustic soda and with water. The solution was dried with calcium chloride, and the ether and most of the ethyl benzoate were distilled off, the latter under reduced pressure. Vacuum distillation of the residue gave: Fraction I, b.p. 68° (3 mm) (ethyl benzoate); Fraction II, 1.1 g, b.p. 100-130° (3 mm); Fraction III, 3.3 g, b.p. 136-155° (3 mm). Fraction II, after hydrolysis and further treatment under the conditions used for Fraction II in the methyl benzoate experiment, gave a feeble reaction for phenol; the precipitate formed on acidification was found to be benzoic acid. When cooled, Fraction III partially crystallized. The crystals were separated and recrystallized from alcohol, when they amounted to 0.8 g, melting, both alone and in admixture with known phenyl benzoate, at 69-70°.

The oil separated from the crystals was hydrolyzed at the boil with 30% methanolic caustic soda. Methanol was then distilled off, water was added, and the undissolved residue was filtered off, boiled with concentrated hydrochloric acid, and recrystallized from ethanol (yield 0.08 g). Its melting point, alone and in admixture with known 4-biphenylcarboxylic acid, was 222°. The filtrate from the precipitate of sodium 4-biphenylcarboxylate was acidified, and the precipitate formed was recrystallized from petroleum ether and ethanol (yield 1.01 g). Its melting point, alone and in admixture with known 3-biphenylcarboxylic acid, was 163-164°.

d) Decomposition in Benzonitrile. The diazonium salt (38 g) was added over a period of one hour to 74 g of benzonitrile at 80°. The mixture was then maintained at 80° for one hour. The mixture was dissolved in ether, and the solution was washed with 10% caustic soda, when a precipitate formed and was filtered off (Precipitate A). The ether solution was washed with water and dried with calcium chloride. Ether was distilled off, and benzonitrile was distilled off under reduced pressure. Vacuum distillation of the residue yielded: Fraction I, 2.5 g, b.p. 73-166° (3 mm); Fraction II, 7.4 g, b.p. 166-200° (3 mm); Fraction III, 3.02 g, b.p. 255-275° (3 mm).

Fraction I partially crystallized. The crystals were separated from the oil and recrystallized from alcohol (1.3 g, m.p. 163°). Fraction II crystallized completely; after recrystallization from alcohol its melting point, alone and in admixture with known benzanilide, was 163°. Fraction III was a caramel-like viscous mass, from which by crystallization and freezing we succeeded in isolating a further 1 g of benzanilide. Precipitate A (1.5 g, m.p. 163°) was also found to be benzanilide. The total yield of benzanilide was 10.95 g (28%).

e) Decomposition in Phenylacetonitrile. Benzenediazonium fluosilicate (42 g, i.e. 1 mole) was added over a period of 90 minutes to 70 g (5 moles) of phenylacetonitrile at 90°. The reaction mixture immediately became dark-colored, and decomposition proceeded vigorously with evolution of white fumes and nitrogen. The mixture was maintained at 80° for one hour. The mixture was cooled and dissolved in ether. The ether solution was washed with 10% caustic soda solution and with water, and it was then dried over sodium sulfate. Ether and phenylacetonitrile were distilled off, and vacuum distillation of the residue gave: Fraction I, 6 g, b.p. 155-195° (5 mm), and Fraction II, 14.7 g, b.p. 200-240° (5 mm).

Fraction I partially crystallized. The crystals were filtered off and recrystallized from heptane and ethanol (yield 4 g). The melting point of the product, alone and in admixture with known 2-phenylacetanilide, was 114°. Fraction II crystallized completely and melted at 114° after recrystallization from alcohol. The total yield of 2-phenylacetanilide was 18.7 g (36%). Solvent was distilled from the mother liquors from the crystallization of 2-phenylacetanilide, and they were then boiled with concentrated hydrochloric acid for 12 hours. The hydrochloric acid solution was steam-distilled. The distillate was extracted with ether. The ether was distilled off, and the residue was made alkaline and again steam-distilled; the second distillate

was extracted with ether. The extract was dried and ether was distilled off, when a few drops of a viscous oil remained. Treatment of this with 2,4-dinitrophenylhydrazine in ethanol and hydrochloric acid gave a very small amount of a precipitate melting at 231-234° (the 2,4-dinitrophenylhydrazone of deoxybenzoin melts at 204°).

f) Decomposition in Acetophenone. Benzenediazonium fluosilicate (42 g, i.e. 1 mole) was added over a period of 90 minutes to 71.6 g (5 moles) of acetophenone at 75°. During the addition the temperature rose to 80°, and it was maintained at 80° for one hour. The mixture was cooled and dissolved in ether. The ether solution was washed with 10% caustic soda and with water, and it was then dried with sodium sulfate. Ether was distilled off, and most of the acetophenone was distilled off under reduced pressure. Vacuum distillation of the residue gave: Fraction I, 3.5 g, b.p. 75-120° (5 mm); Fraction II, 5.6 g, b.p. 120-205° (5 mm); Fraction III, 6.3 g, 205-265° (5 mm).

Fraction II was again vacuum-fractionated; Fraction I', 0.31 g, b.p. 100-150° (5 mm); Fraction II', 1.63 g, b.p. 157-159° (5 mm); Fraction III', 1.26 g, b.p. 159-160° (5 mm).

A solution of Fraction II' in dioxane was treated with a solution of iodine in alkaline potassium iodide solution. The iodoform formed was filtered off, and dioxane was distilled from the filtrate. When the product was acidified with hydrochloric acid, a precipitate formed and was crystallized from ethanol, when it melted at 162-163°, both alone and when mixed with known 3-biphenylcarboxylic acid. Fraction III' solidified and was crystallized from acetone (yield 0.4 g); its melting point, both alone and in admixture with known 4'-phenylacetophenone, was then 118-119°. Fraction III was subjected to the same haloform scission as Fraction II'. The product was 1.5 g of 3-biphenylcarboxylic acid; after being crystallized from alcohol, it melted, both alone and in admixture with known 3-biphenylcarboxylic acid, at 162-163°. In all, 1.8 g of 3-biphenylcarboxylic acid was obtained.

SUMMARY

1. The phenyl that is formed when benzenediazonium fluosilicate is decomposed in a medium consisting of a benzene derivative containing a meta-orienting group enters the latter in the meta position: in nitrobenzene it gives 3-nitrobiphenyl; in benzoic esters it gives mainly 3-biphenylcarboxylic acid (and also phenyl benzoate); in acetophenone it gives mainly 3'-phenylacetophenone. In benzonitrile and in phenylacetonitrile, the decomposition results in the formation of benzanilide and 2-phenylacetanilide respectively.

2. These reactions prove that the decomposition of benzenediazonium fluosilicate is of the heterolytic type, a phenol cation being formed.

STRUCTURE OF SOME ORGANIC COMPOUNDS CONTAINING TIN AND PHOSPHORUS

B. A. Arbuzov and N. P. Grechkin

Some years ago, in collaboration with Pudovik we prepared various types of organic compounds containing tin and phosphorus by the action of some alkyltin halides on esters of acids containing tervalent phosphorus [1-4]. Analogous syntheses were carried out by Arbuzov and Pudovik with alkylsilicon halides [5] and by Kamai and Belcronova with alkylarsenic halides [6]. We supposed that the course of these reactions would be analogous to that of the Arbuzov rearrangement, so that the products would contain direct linkages between tin and phosphorus and between silicon and phosphorus.

$$(RO)_3P + R_3SnHal \rightarrow (RO)_2P(O)SnR_3 + RHal \quad (1a)$$

$$2(RO)_3P + R_2SnHal_2 \rightarrow [(RO)_2P(O)]_2SnR_2 + 2RHal \quad (1b)$$

$$PhP(OR)_2 + R_3SnHal \rightarrow \begin{matrix} Ph \\ RO \end{matrix}\!\!>\!P(O)SnR_3 + RHal \quad (2a)$$

$$2PhP(OR)_2 + R_2SnHal_2 \rightarrow \left[\begin{matrix} Ph \\ RO \end{matrix}\!\!>\!P(O)\right]_2SnR_2 + 2RHal \quad (2b)$$

$$Ph_2POR + R_3SnHal \rightarrow Ph_2P(O)SnR_3 + RHal \quad (3a)$$

$$2Ph_2POR + R_2SnHal_2 \rightarrow [Ph_2P(O)]_2SnR_2 + 2RHal \quad (3b)$$

$$(RO)_3P + R_3SiHal \rightarrow (RO)_2P(O)SiR_3 + RHal \quad (4)$$

In the decomposition of such products with hydrochloric acid, it was to be expected that alkyltin chlorides would be formed together with phosphorus, phenylphosphonous, diphenylphosphinous acids, respectively. Actually, in all cases we succeeded in isolating the corresponding tin derivatives, but only in the decomposition of the products of reaction (3) did we isolate and identify diphenylphosphinic acid, the formation of which could be explained by the oxidation of the diphenylphosphinous acid originally formed.

In 1950 two papers by Malatesta and coworkers [7, 8] were published, and these express a different view on the course of the reactions (1), (2), (3), and (4) and the structure of the final tin-phosphorus and silicon-phosphorus organic compounds. Malatesta considers that in the reactions of triethyl phosphite with triethyltin iodide and with diethyltin diiodide, and also with bromotriethylsilane, the phosphorous ester is first isomerized into diethyl ethylphosphonite, which then, reacting with the halogen compound of tin or silicon, gives the corresponding mixed triethylstannyl or triethylsilyl ester of ethylphosphonic acid in which tin or silicon is attached to phosphorus through oxygen, for example:

When the same tin derivative reacts with diethyl ethylphosphonate, the same product is obtained, its melting point being undepressed by admixture of the product of the reaction with the phosphorous ester. Only ethylphosphonic acid was isolated from the hydrolysis products.

After checking the results of our previous investigations, we came to the conclusion that Malatesta's views are correct. We hydrolyzed a comparatively large amount of the substance obtained from the reactants given in equation (2b) and obtained a fairly good yield of ethylphenylphosphinic acid, the formation of which is in accord with the course of the reaction proposed by Malatesta and is in conflict with reaction according to the scheme of the Arbuzov rearrangement. When ethyl ethylphenylphosphinate was treated with a dialkyltin dihalide, the product was similar to that of the reaction between diethyl phenylphosphonite and the same tin derivative:

In the case of the reaction of alkyltin halides with ethyl diphenylphosphinite, the Malatesta reaction, with formation of a product containing the P—O—Sn linkage, is impossible because the ester isomerizes into ethyldiphenylphosphine oxide, which does not react with alkyltin halides. After careful purification of the products of the reaction between ethyl diphenylphosphinite and diethyltin dichloride, we concluded that the crystalline product has the structure:

and is formed from ethyl diphenylphosphinate present as impurity in the diphenylphosphinous ester or is formed as a result of an intramolecular oxidation-reduction reaction:

Experiments carried out in order to verify the possibility of such a change did not give positive results. An

attempt to oxidize ethyl diphenylphosphinite into ethyl diphenylphosphinate with oxygen was also unsuccessful.

EXPERIMENTAL

Action of Diethyltin Diiodide on Diethyl Ethylphosphonate. A mixture of 15.4 g (1 mole) of the iodide and 11.8 g (2 moles) of the ester was heated in a flask fitted with a condenser set for distillation. When the temperature of the solution was 125°, ethyl iodide began to distill over, the total amount collected being 8 g (72%). The residue in the flask solidified; the yield (16.9 g) was almost quantitative. Recrystallization from butyl alcohol did not affect the melting point (261-263°), and a mixture test with the substance obtained from the same iodide and triethyl phosphite showed no depression.

Action of Diethyltin Diiodide on Ethyl Ethylphenylphosphinate. Reaction was between 5.2 g (2 moles) of the ester and 5.7 g (1 mole) of the iodide. A solution of the tin compound in the ester was heated in a flask fitted with a condenser set for distillation, and the crystalline residue remaining after distillation of ethyl iodide was washed with a mixture of alcohol and ether. The yield was 5.3 g (78%), and the substance melted with decomposition at 292-294° (measured in a block). There was no depression in a mixture test with the product obtained from diethyl phenylphosphonite and diethyltin diiodide.

Hydrolysis. The substance (3 g) was dissolved in concentrated hydrochloric acid (40 ml). The solution was set aside for 48 hours at room temperature and was then evaporated down several times, first with hydrochloric acid, and then with water until the whole of the hydrochloric acid had been removed. The residue crystallized out; 1.8 g, m.p. 79-80° (from benzene). There was no depression of melting point in a mixture test with a sample of ethylphenylphosphinic acid obtained by the hydrolysis of ethyl ethylphenylphosphinate. Hydrolysis of the organic compound of tin and phosphorus obtained from the phosphonous ester also gave ethylphenylphosphinic acid.

Action of Diethyltin Dichloride on Ethyl Diphenylphosphinite. A mixture of 5.9 g (2 moles) of the ester and 3.18 g (1 mole) of the chloride was heated in an atmosphere of dry nitrogen until ethyl chloride ceased to be evolved; the maximum temperature attained by the solution was 210°. When cooled in a current of nitrogen, the reaction mass crystallized out. After being washed with alcohol and ether, the crystals melted at 346-349° (measured in a block).

	Found %:	C 54.67; 54.66;	H 5.09; 4.95
$C_{28}H_{30}O_4P_2Sn$.	Calculated %:	C 55.00;	H 4.94

Ethyldiphenylphosphine oxide was isolated from the filtrate. When the substance was hydrolyzed with concentrated hydrochloric acid, almost quantitative yields were obtained of diphenylphosphinic acid, m.p. 192-194°, and diethyltin dichloride, m.p. 82-84°.

SUMMARY

On the basis of Malatesta's results and of our confirmatory experiments, it must be considered that the organic compounds of tin and phosphorus under consideration are esters of phosphorus acids in which tin is linked to phosphorus through oxygen.

REACTION OF O,O-DIALKYL HYDROGEN PHOSPHORODITHIOATES WITH VINYL SULFIDES

T. A. Mastryukova, E. N. Prilezhaeva, N. I. Uvarova, M. F. Shostakovsky, and M. I. Kabachnik

Addition reactions between O,O-dialkyl hydrogen phosphorodithioates and various unsaturated compounds have recently attracted much attention. As shown recently [1], O,O-dialkyl hydrogen phosphorodithioates are relatively strong acids ($K \approx 10^{-2}$), having ionization constants that are much higher than those of most thiols and thio carboxylic acids. Moreover, these compounds are readily oxidized with the formation of compounds containing a disulfide bond [2]. This reaction, which is characteristic of all thiol compounds, indicates the ready formation of thiol radicals. It might be expected, therefore, that O,O-dialkyl hydrogen phosphorodithioates would readily add at double bonds, the mechanism of the reaction being either ionic or free-radical depending on the experimental conditions and the character of the unsaturated compound used. Correspondingly, addition products should be readily formed by reaction both in accordance with and also contrary to Markovnikov's rule.

In some of the papers that have been published on this matter, the structures of the addition products were not proved, in some cases it being assumed that addition proceeded contrary to the rule [3, 4, 5], and in others that it proceeded in accordance with the rule [6]. The question has been investigated in greater detail for the case of reaction between O,O-diethyl hydrogen phosphorodithioate and unsymmetrical olefins [7, 8]. The authors developed a reliable method for proving the structures of the resulting addition products by scission with sodium alkoxide, and they showed that, in the presence of a peroxide, pure O,O-diethyl hydrogen phosphorodithioate adds to 1-octene and to styrene exclusively contrary to Markovnikov's rule:

$$CH_2 = CHR + (C_2H_5O)_2PSSH \xrightarrow{\text{peroxide}} (C_2H_5O)_2PSSCH_2CH_2R. \qquad (1)$$

In absence of peroxides, addition in accordance with the rule can be readily brought about:

$$CH_2 = CHR + (C_2H_5O)_2PSSH \longrightarrow (C_2H_5O)_2PSSCH(CH_3)R. \qquad (2)$$

A catalyst for "normal" addition - which at the same time decomposes peroxides - is the sulfide P_4S_3, which is present in undistilled O,O-diethyl hydrogen phosphorodithioate prepared from alcohol and phosphorus pentasulfide [7, 9]. The presence of this sulfide as impurity explains the "normal" addition of unpurified O,O-dialkyl hydrogen phosphorodithioates to unsymmetrical olefins observed previously by the same authors [8].

It is probably because of their high acidity that O,O-dialkyl hydrogen phosphorodithioates, unlike thiols, have a high rate of uncatalyzed "normal" addition*. In this connection it was considered to be of interest to study the addition of O,O-dialkyl hydrogen phosphorodithioates to the double bond of vinyl sulfides. A study of the ionic reactions of the latter [11] showed that their double bond is somewhat less nucleophilic than that of the strongly nucleophilic vinyl ethers. Vinyl sulfides are however considerably more nucleophilic than unsymmetrical olefins. Nevertheless, some thiols, including benzenethiol, add so readily under normal conditions

* In absence of peroxides, aliphatic thiols, benzenethiol, and thio carboxylic acids either do not add at all to olefins, or add extremely slowly [10].

to vinyl sulfides in the direction contrary to that required by Markovnikov's rule:

$$CH_2 = CHSR' + R''SH \longrightarrow RSCH_2 - CH_2SR', \quad (3)$$

that the occurrence of this reaction forms a substantial obstacle in the synthesis of vinyl sulfides from thiols and acetylene [12-14]. In order to suppress "abnormal" addition of ethanethiol to ethyl vinyl sulfide, considerable amounts of antioxidant must be present. Under these conditions the thiol slowly reacts in accordance with Markovnikov's rule [13].

The reactions between O,O-dialkyl hydrogen phosphorothioates and vinyl sulfides and ethers are referred to in a patent [6]. The authors consider that in both cases addition is in accordance with Markovnikov's rule:

$$CH_2 = CHSR' + (RO)_2PSSH \longrightarrow (RO)_2P(S)SCH(CH_3)SR', \quad (4)$$

but they give no proofs of the structures of their products. Moreover, they do not give the constants of the products and do not indicate the degree of purity of the starting materials.

We have studied the addition of O,O-diethyl and -diisobutyl hydrogen phosphorodithioates to a series of vinyl sulfides, namely, ethyl, butyl, and 2-butoxyethyl vinyl sulfides. All of the reactants were taken in the freshly distilled form, but no special precautions were taken to remove oxygen and traces of peroxides. The reactions were all exothermic, and the only products were O,O-dialkyl S-1-alkylthioethyl phosphorodithioates, which were isolated in 60-80% yield. Hence, addition occurred in accordance with Markovnikov's rule*. The addition of 0.1% of the active free-radical initiator 2,2'-azobis[2-methylpropionitrile] - which effects the abnormal addition of hydrogen sulfide and thiols to alkyl and aryl vinyl ethers [15] - did not affect the direction of the reaction.

All of the products (Table 1) are colorless oily liquids which are very readily superheated in the distillation process. They are readily soluble in various organic solvents. They are oxidized with difficulty by nitric acid.

In order to prove the structure of the products, O,O-diethyl S-1-ethylthioethyl and S-1-butylthioethyl phosphorodithioates were synthesized by a different method which confirmed their structure, namely by the alkylation of potassium O,O-diethyl phosphorodithioate with the corresponding alkyl 1-chloroethyl sulfide:

$$(C_2H_5O)_2PSSK + CH_3CH(SR)Cl \rightarrow (C_2H_5O)_2P\begin{matrix} S \\ \diagdown \\ \diagup \\ SCHSR \end{matrix}\begin{matrix} CH_3 \\ \\ \\ \end{matrix} + KCl, \quad (5)$$

The required alkyl 1-chloroethyl sulfides were prepared by the hydrochlorination of vinyl ethers under the conditions described previously [11]:

$$CH_2 = CHSR + HCl \longrightarrow CH_3 - CH(SR)Cl. \quad (6)$$

The constants of the substances prepared by the two methods were in close agreement (Table 2).

As another method for proving the structure, the reaction with mercuric chloride in an ethanol medium was used. This reaction has been proposed previously for the quantitative determination of monothioacetals [17, 18] and symmetrical mercaptals [13, 19], which are split by the action of mercuric chloride with the elimination of one and two equivalents, respectively, of hydrogen chloride:

* It was established by a special experiment on the reaction between O,O-diethyl hydrogen phosphorodithioate and ethyl vinyl sulfide that an O,O-dialkyl hydrogen phosphorodithioate purified via a salt in accordance with Bacon and le Suer's method [7] also adds to a vinyl sulfide in the direction required by Markovnikov's rule.

TABLE 2

Specimens of O,O-Diethyl S-1-Alkylthioethyl Phosphorodithioates Prepared by Two Different Methods

Formula of substance	Method of preparation	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
	By addition	109—110 (2.5)	1.5290	1.1332
	By alkylation of salt	109—110 (2.5)	1.5289	1.1391
	By addition	109—110 (2)	1.5198	1.0965
	By alkylation of salt	109—110 (2)	1.5200	1.0969

$$CH_3CH\begin{matrix}SR'\\OR\end{matrix} + HgCl_2 + 2C_2H_5OH \rightarrow CH_3CH(OC_2H_5)_2 + R'SHgCl + HCl + ROH, \quad (7)$$

$$CH_3CH\begin{matrix}SR\\SR\end{matrix} + 2HgCl_2 + 2C_2H_5OH \rightarrow CH_3CH(OC_2H_5)_2 + 2RSHgCl + 2HCl. \quad (8)$$

Owing to the low alcohol-solubility of the alkylthiomercury chlorides formed, the reaction goes practically to completion. The isomeric ethers of 2-mercaptoethanol and 1,2-ethanedithiol give the complex salts usually obtained from sulfides when treated with mercuric chloride, and no hydrogen chloride is eliminated [13, 17].

The products of the addition of O,O-dialkyl hydrogen phosphorodithioates to vinyl sulfides behave toward mercuric chloride in an alcoholic medium as members of a series of phosphorus-containing mercaptals, yielding two equivalents of hydrogen chloride and decomposing according to the equation:

$$CH_3CH\begin{matrix}SR'\\SPS(OR)_2\end{matrix} + 2HgCl_2 + 2C_2H_5OH \rightarrow CH_3CH(OC_2H_5)_2 + 2HCl + R'SHgCl + (RO)_2P(S)SHgCl. \quad (9)$$

In the scission of O,O-diethyl S-1-ethylthioethyl phosphorodithioate with alcoholic mercuric chloride, products corresponding to the above equation were detected. Ethylthiomercury chloride was isolated, and hydrochloric acid and acetaldehyde diethyl acetal were titrated quantitatively. The acetaldehyde obtained by hydrolysis of the acetal was identified as its dinitrophenylhydrazone. As regards the chloromercury O,O-diethyl phosphorodithioate, we did not succeed in isolating it in the pure state owing to the occurrence of disproportionation during recrystallization:

$$2(C_2H_5O)_2PSSHgCl \rightarrow HgCl_2 + [(C_2H_5O_2)PSS]_2Hg. \quad (10)$$

Mercury bis(O,O-diethyl phosphorodithioate) was isolated and identified. Chloromercury O,O-diethyl phosphorodithioate prepared in a known way also underwent the same disproportionation when recrystallized.

The specimens of O,O-dialkyl S-1-alkylthioethyl phosphorodithioates prepared by the two methods reacted in identical manner with alcoholic mercuric chloride.

EXPERIMENTAL

Freshly distilled reactants were used in the experiments. The alkyl vinyl sulfides were prepared from thiols and acetylene [12, 13, 20], and the O,O-dialkyl hydrogen phosphorodithioates were prepared from phosphorus pentasulfide and alcohols and were purified by vacuum fractionation [2, 21].

Preparation of O,O-Dialkyl S-1-Alkylthioethyl Phosphorodithioates

In all of the experiments the O,O-dialkyl hydrogen phosphorodithioate was added dropwise with stirring to a slight excess of the vinyl sulfide, the rate of addition being such that the temperature of the reaction mixture was maintained within the range 60-62°. When addition was complete, the temperature rapidly fell to that of the room. The mixture was stirred for a further 30 minutes and was set aside overnight. It was then vacuum-fractionated.

O,O-Diethyl S-1-Ethylthioethyl Phosphorodithioate. This was prepared from 6.0 g (0.068 mole) of ethyl vinyl sulfide and 9.3 g (0.05 mole) of O,O-diethyl hydrogen phosphorodithioate: b.p. 109-110° (2.5 mm); n_D^{20} 1.5290; d_4^{20} 1.1392; yield 10.0 g (73%).

Synthesis of O,O-Dialkyl S-1-Alkylthioethyl Phosphorodithioates from Alkyl 1-Chloroethyl Sulfides

Preparation of O,O-Diethyl S-1-Ethylthioethyl Phosphorodithioate. In a flask fitted with stirrer, 11.2 g (0.09 mole) of 1-chloroethyl ethyl sulfide was added dropwise to 11.2 g (0.05 mole) of potassium O,O-diethyl phosphorodithioate suspended in 25 ml of dry ether. The temperature rose to 35° and the ether boiled. The reaction was heated in a water bath at 40° for three hours. The precipitate of potassium chloride was filtered off (3.98 g; the theoretical amount was 3.72 g). The filtrate was dried over calcined sodium sulfate and vacuum-fractionated; b.p. 109-110° (2.5 mm); n_D^{20} 1.5289; d_4^{20} 1.1391; yield 8.5 g (62%); found MR 74.30; calculated for $C_8H_{19}O_2PS_2$ MR 74.01.

Preparation of O,O-Diethyl S-1-Butylthioethyl Phosphorodithioate. This was prepared in a similar way from 8.0 g (0.05 mole) of butyl 1-chloroethyl sulfide and 11.2 g (0.05 mole) of potassium O,O-diethyl phosphorodithioate in 20 ml of absolute ether; b.p. 109-110° (2 mm); n_D^{20} 1.5200; d_4^{20} 1.0969; yield 10.8 g (71%); found MR 83.82; calculated for $C_{12}H_{25}O_2PS_2$ MR 83.25.

Reaction of O,O-Dialkyl S-1-Alkylthioethyl Phosphorodithioates with Mercuric Chloride

Reaction of O,O-Diethyl S-1-Ethylthioethyl Phosphorodithioate with Mercuric Chloride. A solution of 2.2 g (0.0081 mole) of mercuric chloride in 11 ml of 96% ethanol was added to 1 g (0.0036 mole) of O,O-diethyl S-1-ethylthioethyl phosphorodithioate. The white precipitate that quickly formed was filtered off after three hours and washed with cold alcohol. The alcohol was added to the filtrate, and the precipitate was vacuum-dried (weight 1.8 g). After the filtrate had stood for five days, a further 0.15 g of crystals came down. Titration of part of the filtrate with standard caustic soda solution gave a hydrochloric acid content of 97.7% of the theoretical value. The filtrate was evaporated to dryness at a residual pressure of 10 mm, the distillate being collected in a trap cooled with dry ice and acetone. Determination of acetaldehyde diethyl acetal in part of the distillate by the hydroxylamine method gave 92.9% of the theoretical value. To the remaining part of the distillate, 0.45 g of dinitrophenylhydrazine and 0.5 ml of concentrated hydrochloric acid were added; the mixture was boiled for 30 minutes and then cooled, when golden needles of acetaldehyde dinitrophenylhydrazone came down (m.p. after recrystallization 163-164°). The weight of the dry residue remaining after the distillation was 0.6 g, reduced to 0.3 g after treatment with water to remove unchanged mercuric chloride. The residue was not treated further since it rapidly turned black. The total weight of mercury salts isolated was 2.25 g (theory requires 2.6 g).

The salts that came down from the solution (1.95 g) were extracted several times with boiling alcohol (75 ml in all). The weight of the residue that remained undissolved was 0.8 g. Recrystallization from boiling xylene [22] gave pearly leaves, which did not melt, but gradually decomposed above 250°.

	Found %:	C 8.40;	8.47;	H 1.82;	2.09
C_2H_5SHgCl	Calculated %:	C 8.08;		H 1.68	

When cooled, the alcohol yielded 0.7 g of fine crystals, which were heated with boiling benzene for one hour in order to complete disproportionation. The decomposition temperature of the crystals that separated from the benzene was 121-121.5°. In admixture with known mercury bis[O,O-diethyl phosphorodithioate] (see below) it melted with decomposition at 121-122°.

	Found %:	C 16.43;	16.57;	H 3.51;	3.40
$C_8H_{20}O_4P_2S_4Hg$	Calculated %:	C 16.82;		H 3.53	

Preparation of Chloromercury O,O-Diethyl Phosphorodithioate $(C_2H_5O)_2PSSHgCl$. An aqueous solution of 13.6 g (0.05 mole) of mercuric chloride was added to an aqueous solution of 11.2 g (0.05 mole) of potassium O,O-diethyl phosphorodithioate. There was an immediate white precipitate, which was filtered off, washed with a large amount of water, and dried. It melted with decomposition at 126-127°; the yield was quantitative.

	Found %:	C 11.67;	11.72	H 2.63;	2.50
$C_4H_{10}O_2PS_2HgCl$	Calculated %:	C 11.40;		H 2.45	

After two recrystallizations from benzene the substance melted at 122-123°, but the carbon and hydrogen contents were greatly increased. After five recrystallizations from benzene the substance had m.p. 121-122° and its composition corresponded to complete disproportionation.

	Found %:	C 16.63;	16.41;	H 3.46;	3.40
$C_8H_{20}O_4P_2S_4Hg$	Calculated %:	C 16.82;		H 3.53	

Preparation of Mercury Bis(O,O-diethyl phosphorodithioate). An aqueous solution of 5.6 g (0.025 mole) of potassium O,O-diethyl phosphorodithioate was added to an aqueous solution of 3.4 g (0.013 mole) of mercuric chloride. A voluminous white precipitate of the mercury compound formed. It was filtered off, washed with water, and dried. The yield was quantitative. After being recrystallized from ben-

zene; it melted with decomposition at 121-122°.

Found %: C 16.48; 16.60; H 3.50; 3.55

$C_8H_{20}O_4P_2S_4Hg$. Calculated %: C 16.82; H 3.53

TABLE 3

Titration of O,O-Dialkyl S-1-Alkylthioethyl Phosphorodithioates $(RO)_2PSSCH(CH_3)SR'$

R	R'	Method of preparation	Equivalent		Content of eliminable S (%)	
			found	calc.	found	calc.
C_2H_5	C_2H_5	Addition of distilled O'O-hydrogen phosphorothioate to ethyl vinyl sulfide	140.8 139.7	137.22	23.91 23.72	23.37
C_2H_5	C_2H_5	Ditto, but with purification of the O,O-diethyl hydrogen phosphorodithioate via the salt [7]	135.2 137.9	137.22	23.02 23.42	23.37

i-C_4H_9	$CH_2CH_2OC_4H_9$	Addition under usual conditions	203.4 197.3	201.3	16.09 15.61	15.93
i-C_4H_9	$CH_2CH_2OC_4H_9$	Addition in presence of 0.1% of 2,2'-azobis[2-methylpropionitrile]	203.1 201.7	201.3	16.07 15.94	15.93

Quantitative Determination of O,O-Dialkyl S-1-Alkylthioethyl Phosphorodithioates

The titration was carried out as already described for monothioacetals [17] and vinyl sulfides [12]. A weighed amount (0.0005-0.001 mole) of O,O-dialkyl S-1-alkylthioethyl phosphorodithioate was placed in a conical flask, and 5-6 times as much (in moles) of mercuric chloride was added as a 20% solution in ethanol. After 1-2 hours the acid liberated was titrated with 0.1 N NaOH to a yellow color with methyl orange. It was found necessary to shake the precipitate well during the titration in order to avoid the formation of mercuric oxide.

The calculated equivalents on the basis of equation (9) and the contents of eliminable sulfur are given in Table 3.

SUMMARY

1. It was shown that O,O-dialkyl hydrogen phosphorodithioates readily add to vinyl sulfides in accordance with Markovnikov's rule.

2. A series of O,O-dialkyl S-1-alkylthioethyl phosphorodithioates were prepared. Their structure was proved by two methods: synthesis from alkyl 1-chloroethyl sulfides, and scission by means of mercuric chloride in ethanol.

ORGANOBORON COMPOUNDS

COMMUNICATION 8. SYNTHESIS AND PROPERTIES OF DIARYLBORINIC ACIDS

B. M. Mikhailov and V. A. Vaver

In a previous paper [1] we have described the preparation of diphenylborinic acid and its derivatives. The properties of these compounds and the desire to correct some inaccuracies in data reported in the literature for some other diarylborinic acids prompted us to synthesize a few more representatives of this class of compounds.

We prepared di-1-naphthyl-, bis-p-bromophenyl-, and bis-p-chlorophenyl-borinic acids. The isobutyl esters of these acids were isolated in 40-63% yield, together with the corresponding diisobutyl areneboronates, from the reaction products obtained by treating two equivalents of arylmagnesium bromide with one equivalent of triisobutyl borate. The reactions were carried out under the same conditions as those used in the synthesis of isobutyl diphenylborinate [1].

$$2ArMgBr + B(i\text{-}OC_4H_9)_3 \longrightarrow Ar_2B(i\text{-}OC_4H_9) + i\text{-}C_4H_9OMgBr$$

$$Ar = 1\text{-}C_{10}H_7-;\ P\text{-}BrC_6H_4-;\ P\text{-}ClC_6H_4-.$$

A characteristic property of these diarylborinic esters is their stability to hydrolysis by water and dilute mineral acids. A second peculiarity is their ability to dissolve in caustic alkalis with formation, as in the case of isobutyl diphenylborinate [1], of salts of diarylhydroxyisobutoxyboric acids*:

When aqueous solutions of such salts are heated, the alkoxy group of the anion is hydrolyzed with formation of a salt of diaryldihydroxyboric acid:

Barium salts of diaryldihydroxyboric acids are readily prepared by direction treatment of diarylborinic esters with saturated baryta water. It is probable that in this case the same hydrolysis reaction occurs with the anion of the barium salt of the alkoxydiarylhydroxyboric acid, which is formed in the first place, but it proceeds more rapidly as a result of the poor solubility in water of barium salts of diaryldihydroxyboric acids.

* As there is no recognized system of nomenclature for compounds of this type, they are named here by an adaptation of the nomenclature for inorganic complex compounds, "organic" names, however, being given for radicals (e.g. hydroxy, not hydroxo). - Publisher.

Di-1-naphthyl- and bis-p-bromophenyl-boinic esters react readily also with aqueous ammonia, ammonium salts of the corresponding diaryldihydroxyboric acids being formed. Bis-p-chlorophenylborinic esters are exceptional in this respect; they do not react with aqueous ammonia, neither at room temperature nor when heated.

When salts of general formula

$$[Ar_2B(OH)_2]M$$

M = K; Na; $\frac{Ba}{2}$; NH_4; Ar = 1-$C_{10}H_7$–; P-BrC_6H_4–; P-ClC_6H_4–

are treated with acid, they are converted into acids. Salts of dihydroxydi-1-naphthyl- and bis-p-bromophenyldihydroxy-boric acids give the corresponding diarylborinic acids, but salts of bis-p-chlorophenyldihydroxyboric acid, like those of the corresponding diphenyl compound, give a monohydrate of the diarylborinic acid.

Unlike diphenylboiinic acid, the diarylborinic acids now prepared do not form anhydrides when heated in a vacuum, but are converted under these conditions into areneboronic acids with elimination of one aryl radical. Anhydrides can be prepared by treating the acids with thionyl chloride, this being demonstrated for the case of di-1-naphthylborinic acid:

$$(1\text{-}C_{10}H_7)_2B(OH) + SOCl_2 \longrightarrow (1\text{-}C_{10}H_7)_2B\text{–}O\text{–}B(1\text{-}C_{10}H_7)_2.$$

In conclusion, we must discuss data reported in the literature on the diarylborinic acids that we have prepared. Di-1-naphthylborinic acid was isolated recently by Letsinger and coworkers [2], who obtained it by the acid hydrolysis of its aminoethyl ester. As regards the bis-p-bromophenyl- and bis-p-chlorophenyl-borinic acids described by Konig and Scharinbeck [3] and by Melnikov and Rokitskaya [4], it is clear from the method used for the preparation that the authors could not have isolated these substances.

Konig and Scharinbeck, and later Melnikov and Rokitskaya, prepared their organoboron compounds by reaction between equivalent amounts of arylmagnesium bromide and tributyl borate. After treatment of the reaction products with dilute acid and separation of areneboronic acid, at the best the residue could contain a diarylborinic ester, which is not hydrolyzed under these conditions, but it could not contain a diarylborinic acid.

For bis-p-bromophenylborinic acid, Konig and Scharinbeck give m.p. 113°, whereas the acid actually melts at 91°. According to Melnikov and Rokitskaya's results, bis-p-chlorophenylborinic acid corresponds in composition to $(ClC_6H_4)_2B(OH)$, whereas its actual composition corresponds to $(ClC_6H_4)_2B(OH)H_2O$. Moreover, Melnikov and Rokitskaya state, incorrectly, that reaction between equimolecular amounts of tributyl borate and p-chlorophenylmagnesium bromide gives bis-p-chlorophenylborinic acid in 17% yield together with a smaller amount of p-chlorobenzeneboronic acid (15%). We repeated Melnikov and Rokitskaya's experiments and showed that, under their conditions, only p-chlorobenzeneboronic acid is obtained and no bis-p-chlorophenylborinic ester is formed.

EXPERIMENT

Isobutyl Di-1-naphthylborinate. With vigorous mechanical stirring, a solution of 0.225 mole (52 g) of triisobutyl borate in 50 ml of absolute ether was added over a period of 15 minutes to 0.5 mole of 1-naphthylmagnesium bromide as a molar solution in a mixture of ether and benzene, the temperature being maintained at −20° to −30°. When addition of the boric ester was complete, the temperature was lowered, −70° to −75°, and the reaction mixture stirred at this temperature for 6-7 hours. The next day the reaction products were treated with 350 ml 5% HCl. The ether-benzene layer was separated, and the aqueous layer was extracted with ether. The combined ether-benzene extracts were dried with calcined sodium sulfate. After distilling off solvents, a yellowish viscous residue remained; after dilution with 50 ml isopentane, this solidified into a crystalline mass. The reaction product was filtered off under suction, thoroughly washed with isopentane, and vacuum-dried. The product, amounting to 47.5 g (63%) was isobutyl di-1-naphthylborinate, m.p. 104-105° (after recrystallization from hexane).

	Found %:	C 85.20; 85.14;	H 6.73; 6.77;	B 3.17; 3.24
$C_{24}H_{23}BO$	Calculated %:	C 85.22;	H 6.85;	B 3.19

Distillation of solvent from the isopentane filtrate and esterification of the residue with isobutyl alcohol resulted in the isolation of 10 g (15%) of diisobutyl 1-naphthaleneboronate, b.p. 166-168° (6 mm) and d_4^{20} 0.9777.

	Found %:	$C_{10}H_7$	43.70;	43.84;	B	3.60;	3.67
$(C_{10}H_7)B(OC_4H_9)_2$.	Calculated %:	$C_{10}H_7$	44.42;		B	3.78	

Isobutyl di-1-naphthylborinate is a colorless crystalline substance, readily soluble in benzene and chloroform, difficultly soluble in petroleum ether and methanol, and insoluble in isopentane. Diisobutyl 1-naphthaleneboronate is a colorless liquid, readily hydrolyzed - even by atmospheric moisture - into 1-naphthaleneboronic acid.

Ammonium Dihydroxydi-1-naphthylborate. A suspension of 10 g of isobutyl di-1-naphthylborinate in 20 ml of methanol was prepared and was stirred vigorously while 15 ml of 30% aqueous ammonia was added. At first the precipitate dissolved completely, and then a colorless crystalline substance was rapidly precipitated. The mixture was stirred for 30 minutes, and the reaction product was then filtered off at the pump, washed with methanol, and vacuum-dried to constant weight. The product, amounting to 8.85 g (97.5%), was ammonium dihydroxydi-1-naphthylborate, m.p. 105-107°. After recrystallization from methanol the substance melted at 107-108°.

	Found %:	$C_{10}H_7$	79.44;	79.84;	B	3.34;	3.20;	N	4.12; 4.09
$[(C_{10}H_7)_2B(OH)_2]NH_4$.	Calculated %:	$C_{10}H_7$	80.17;		B	3.41;		N	4.41

Ammonium dihydroxydi-1-naphthylborate is a colorless crystalline substance, readily soluble in benzene and hot methanol, difficultly soluble in cold methanol, and insoluble in water. In the air it rapidly decomposes with formation of 1-naphthaleneboronic acid and separation of ammonia and naphthalene.

Di-1-naphthylborinic Acid. A suspension of 4.94 g of ammonium dihydroxydi-1-naphthylborate was prepared in 30 ml of ether, and it was stirred vigorously while 5 ml of dilute (1 : 1) hydrochloric acid was added (acid reaction to Congo red). The ether layer was separated, and the remaining solution was extracted with ether. Ether was removed from the combined extracts under reduced pressure, and the residue was heated at 70° for 10-15 minutes. The reaction product was dissolved in a little dry benzene and reprecipitated with 10 ml of isopentane. The product, amounting to 3.15 g (71.7%), was di-1-naphthylborinic acid, m.p. 113-114°. After being recrystallized from petroleum ether, the di-1-naphthylborinic acid melted at 114.5-115°.

	Found %:	C	84.83;	84.90;	H	5.26;	5.38; B 3.91; 3.97
$C_{20}H_{15}BO$.	Calculated %:	C	85.13;		H	5.35;	B 3.83

Di-1-naphthylborinic acid is a colorless crystalline substance, readily soluble in benzene, difficultly soluble in petroleum ether, and insoluble in isopentane. When it is heated above its melting point in a vacuum, no anhydride formation occurs, but elimination of one of the naphthyls as naphthalene slowly occurs with formation of 1-naphthaleneboronic acid.

Di-1-naphthylborinic Anhydride. A solution of 2 g of di-1-naphthylborinic acid in 5 ml of thionyl chloride was refluxed for two hours. Thionyl chloride was removed under reduced pressure, and the residue was crystallized from a mixture of benzene and petroleum ether. The product, amounting to 1.9 g (98%), was di-1-naphthylborinic anhydride, m.p. 190-192°.

	Found %:	$C_{10}H_7$	91.80;	91.96;	B	4.24;	4.20
$(C_{10}H_7)_2BOB(C_{10}H_7)_2$.	Calculated %:	$C_{10}H_7$	92.98;		B	4.34	

Di-1-naphthylborinic anhydride is a colorless crystalline substance, difficultly soluble in benzene and insoluble in petroleum ether and isopentane.

Isobutyl Bis-p-bromophenylborinate. With vigorous mechanical stirring, a solution of 0.25 mole of triisobutyl borate in 100 ml of absolute ether was added over a period of 30 minutes to 0.65 mole of p-bromophenylmagnesium bromide as a molar ethereal solution (prepared by Fink's method [5]), the temperature being maintained at −30° to −60°. The reaction mixture was stirred at −70° to −75° for eight hours. The reaction products were treated with 450 ml of 5% hydrochloric acid. The residue remaining after removal of ether was esterified with 25 ml of isobutyl alcohol and vacuum-fractionated from a Claisen flask in a current of dry nitrogen. Two fractions were collected, b.p. 102-158° and 158-164° (1 mm) respectively. Further frac-

tionation of the reaction products yielded 38.0 g (39%) of isobutyl bis-p-bromophenylborinate, b.p. 161-163° (1 mm), and 30 g (37%) of diisobutyl p-bromobenzeneboronate, b.p. 109-110° (1 mm) and d_4^{20} 1.1583.

	Found %:	BrC_6H_4 78.73;	78.60;	B 2.65;	2.75	
$(BrC_6H_4)_2B(OC_4H_9)$.	Calculated %:	BrC_6H_4 78.80;		B 2.73		
	Found %:	BrC_6H_4 49.72;	49.81;	B 3.27;	3.31	
$(BrC_6H_4)B(OC_4H_9)_2$.	Calculated %:	BrC_6H_4 49.83;		B 3.46		

Isobutyl bis-p-bromophenylborinate is a colorless, very viscous substance, which slowly solidifies at room temperature. It is soluble in most organic solvents, and it slowly oxidizes in the air. Diisobutyl p-bromobenzeneboronate is a colorless liquid, which is very rapidly hydrolyzed when exposed to the atmosphere with formation of p-bromobenzeneboronic acid.

Ammonium Bis-p-bromophenyldihydroxyborate. Isobutyl bis-p-bromophenylborinate (2.25 g) and 30% aqueous ammonia (5 ml) were shaken together. The crystalline precipitate formed was filtered off at the pump, washed with water, and vacuum-dried to constant weight. The product, amounting to 1.85 g (87.3%), was ammonium bis-p-bromophenyldihydroxyborate, m.p. 133-135°, unchanged by recrystallization from benzene.

	Found %:	BrC_6H_4 83.59;	83.42;	B 2.90;	2.91;	N 3.64;	3.65	
$[(BrC_6H_4)_2B(OH)_2]NH_4$.	Calculated %:	BrC_6H_4 83.23;		B 2.89;		N 3.74		

Ammonium bis-p-bromophenyldihydroxyborate is a colorless odorless crystalline substance, soluble in methanol and ethanol, sparingly soluble in benzene, and insoluble in isopentane.

Potassium Bis-p-bromophenyldihydroxyborate. Isobutyl bis-p-bromophenylborinate (1.23 g) was dissolved in the equivalent amount of aqueous caustic potash (3.65 ml of 0.8 N solution), and water was then slowly distilled off in a current of nitrogen under reduced pressure at 60-70°. The residue was a colorless crystalline substance. After recrystallization from a mixture of benzene with some methanol, 0.8 g was obtained.

	Found %:	BrC_6H_4 78.56;	78.67;	B 2.71;	2.73;	K 9.81;	9.84	
$[(BrC_6H_4)_2B(OH)_2]K$.	Calculated %:	BrC_6H_4 78.80;		B 2.73;		K 9.87		

Potassium bis-p-bromophenyldihydroxyborate is extremely soluble in water and alcohols, but insoluble in benzene, petroleum ether, and isopentane. It is converted quantitatively into bis-p-bromophenylborinic acid by treatment with dilute acids.

Bis-p-bromophenylborinic Acid. Ammonium bis-p-bromophenyldihydroxyborate (1.65 g) was treated with dilute hydrochloric acid. The reaction product was extracted with ether. After removal of ether, the residue was diluted with a little isopentane. The product, amounting to 1.30 g (86%) was bis-p-bromophenylborinic acid. After being recrystallized from petroleum ether the acid melted at 90-91°.

	Found %:	C 42.61;	42.69;	H 2.83;	2.66;	B 3.18;	3.17;	Br 47.38	47.10	
$C_{12}H_9BOBr_2$.	Calculated %:	C 42.41;		H 2.67;		B 3.18;		Br 47.03		

Bis-p-bromophenylborinic acid is a colorless crystalline substance, readily soluble in alcohols and benzene, difficultly soluble in petroleum ether, and insoluble in isopentane. It can be prepared also from potassium bis-p-bromophenyldihydroxyborate (0.899 g of the potassium salt gave 0.760 g of acid, m.p. 87-89°, when acidified); the melting point of a mixture with the analyzed sample of bis-p-bromophenylborinic acid was 89-90°.

Isobutyl Bis-p-chlorophenylborinate. With vigorous stirring, a solution of 0.25 mole of triisobutyl borate in 100 ml of absolute ether was added over a period of 30 minutes to 0.6 mole of p-chlorophenylmagnesium bromide as a molar ethereal solution, the temperature being maintained at −30° to −60°. The reaction mixture was then cooled to a temperature of −70° to −75°, and it was stirred at this temperature for 8-9 hours. On the next day the reaction products were treated with 450 ml of 5% hydrochloric acid. The residue remaining after removal of ether from the combined extracts was esterified with 25 ml of isobutyl alcohol, the alcohol was distilled off, and the residue was distilled rapidly from a Claisen flask (in a current of dry nitrogen). Two fractions were collected: 70-145° and 145-155° (2 mm). Further fractionation of the reac-

tion products through a Hempel column in a current of nitrogen gave 31 g (40%) of isobutyl bis-p-chlorophenylborinate, b.p. 134-135° (1 mm) and d_4^{20} 1.0081.

	Found %:	ClC_6H_4	72.66;	72.23;	B	3.55;	3.53;	Cl 23.27; 23.31
$(ClC_6H_4)_2B(OC_4H_9)$.	Calculated %:	ClC_6H_4	72.66;		B	3.52;		Cl 22.80
	Found %:	ClC_6H_4	41.34;	41.09;	B	3.90;	4.09	
$(ClC_6H_4)B(OC_4H_9)_2$.	Calculated %:	ClC_6H_4	41.53;		B	4.03		

Isobutyl bis-p-chlorophenylborinate is a very viscous colorless liquid; it is immiscible with water, but is soluble in most organic solvents. It is rapidly oxidized in the air. Diisobutyl p-chlorobenzeneboronate is a colorless mobile liquid, miscible with most organic solvents. It is immediately hydrolyzed in the atmosphere with formation of p-chlorobenzeneboronic acid.

Barium Bis-p-chlorophenyldihydroxyborate. Isobutyl bis-p-chlorophenylborinate (1.73 g) was shaken for 5-10 minutes with 15 ml of baryta water (saturated at room temperature). The voluminous precipitate that formed after a few minutes was filtered off at the pump, washed with water, and dried to constant weight. The yield of the salt was 1.7 g (89.5%). Barium was determined by heating a weighed sample of the substance with 1N H_2SO_4, the excess of acid being then titrated with 1N NaOH. Boron and chlorophenyl groups were determined in the usual way on a separate sample.

	Found %:	Ba	20.24;	20.26;	ClC_6H_4	65.58;	65.93;	B 3.14; 3.09
$[(ClC_6H_4)_2B(OH)_2]_2Ba$.	Calculated %:	Ba	20.40;		ClC_6H_4	66.28;		B 3.21

Barium bis-p-chlorophenyldihydroxyborate is a colorless crystalline substance. It is insoluble in water, benzene, and isopentane, but readily soluble in methanol and ethanol. When treated with dilute hydrochloric acid it is converted into bis-p-chlorophenylborinic acid.

Bis-p-chlorophenylborinic Acid. Barium bis-p-chlorophenyldihydroxyborate (2.0 g) was shaken with 10 ml of dilute hydrochloric acid (1 : 4). The emulsion that was immediately formed rapidly turned into a precipitate of a colorless crystalline substance, which was filtered off at the pump, washed with water, and dried over calcium chloride. The substance obtained (1.1 g; m.p. 76-78° after reprecipitation by water from alcohol) corresponded in analysis to the monohydrate of bis-p-chlorophenylborinic acid. When dried in a vacuum it decomposed with elimination of chlorobenzene and formation of p-chlorobenzeneboronic acid.

	Found %:	C	54.53;	54.29;	H	4.49;	4.28;	B 4.08; 3.83; Cl 26.36; 26.66
$C_{12}H_{11}BO_2Cl_2$.	Calculated %:	C	53.58;		H	4.12;		B 4.02; Cl 26.36

The monohydrate of bis-p-chlorophenylborinic acid is readily soluble in benzene, methanol, and ethanol, but insoluble in water.

Sodium Bis-p-chlorophenyldihydroxyborate. Isobutyl bis-p-chlorophenylborinate (2.84 g) was dissolved in the equivalent amount of caustic soda (8.4 ml of 1.09N NaOH). The solution was heated to 60-70°, and water was slowly distilled off under reduced pressure. The residue was washed with benzene and vacuum-dried (yield 2.2 g).

	Found %:	Na	7.42;	7.65;	B	3.53;	3.80	
$C_{12}H_{11}BO_2Cl_2Na$.	Calculated %:	Na	7.90;		B	3.72		

Sodium bis-p-chlorophenyldihydroxyborate is very readily soluble in water and alcohols, but is insoluble in benzene, petroleum ether, and isopentane. On acidification it gives the monohydrate of bis-p-chlorophenylborinic acid, m.p. 72-76° (0.3 g of the salt gave 0.25 g of the monohydrate). A mixture of the product with the analyzed sample of bis-p-chlorophenylborinic acid monohydrate melted at 72-76°.

Boron and aryl groups were determined by Wittig's method [6].

SUMMARY

1. The isobutyl esters of di-1-naphthyl-, bis-p-bromophenyl-, and bis-p-chlorophenyl-borinic acids were prepared.

2. It was shown that, when the isobutyl esters of di-1-naphthyl-, bis-p-bromophenyl-, and bis-p-chloro-

phenyl-borinic acids were treated with aqueous solutions of caustic soda, caustic potash, ammonia, and barium hydroxide, salts of the corresponding diaryldihydroxyboric acids were formed.

3. Di-1-naphthyl-, bis-p-bromophenyl, and bis-p-chlorophenyl-borinic acids were prepared by treating salts of di-1-naphthyl-, bis-p-bromophenyl-, and bis-p-chlorophenyl-dihydroxyboric acids with dilute hydrochloric acid.

4. It was shown that data reported in the literature for bis-p-bromophenyl- and bis-p-chlorophenylborinic acids are incorrect.

SYNTHESIS OF ar-CHLORINE-SUBSTITUTED DICHLOROETHYLPHENYLSILANES

K. A. Andrianov and V. A. Odinets

When trichlorophenylsilane is treated with ethylmagnesium bromide, a halogen is readily replaced by an ethyl group with formation of dichloroethylphenylsilane [1]. The reaction between ethylmagnesium bromide and ar-chlorine-substituted trichlorophenylsilanes of various degrees of substitution has not been studied. The replacement of chlorine attached to silicon by ethyl in ar-chlorine-substituted trichlorophenylsilanes is of definite practical and theoretical interest. When ar-chlorine-substituted trichlorophenylsilanes of various degrees of substitution are used in place of trichlorophenylsilane in the reaction with ethylmagnesium bromide, the possibility will arise of the replacement by ethyl not only of chlorine attached to silicon, but also of chlorine present in the aromatic radical. In this paper we give results of a study of the reaction between ethylmagnesium bromide and ar-chlorine-substituted trichlorophenylsilanes.

TABLE 1

Name of substance	Formula	B.p. in °C (p in mm)	d_{20}^{20}	n_D^{20}	MR found	MR calculated
Dichloro(p-chlorophenyl)ethylsilane	$ClC_6H_4(C_2H_5)SiCl_2$	116—118 (7)	1.2947	1.5270	55.06	54.79
Dichloro(2,4-dichlorophenyl)ethylsilane	$Cl_2C_6H_3(C_2H_5)SiCl_2$	130—132 (10)	1.4381	1.5450	58.35	59.23
Dichloro(2,4,6-trichlorophenyl)silane	$Cl_3C_6H_2(C_2H_5)SiCl_2$	142—144 (12)	1.4921	1.5481	64.08	64.07
Dichloroethyl(2,3,4,6-tetrachlorophenyl)silane	$Cl_4C_6H(C_2H_5)SiCl_2$	123—125 (3)	1.5396	1.5618	72.18	69.21
Dichloroethyl(2,3,4,5,6-pentachlorophenyl)silane	$Cl_5C_6(C_2H_5)SiCl_2$	145—147 (3)	1.5896	1.5650	76.82	74.07

Reaction between ethylmagnesium bromide and ar-chlorine-substituted trichlorophenylsilanes was carried out with compounds having different degrees of substitution, namely: trichloro(p-chlorophenyl)silane, trichloro-(2,4-dichlorophenyl)silane, trichloro(2,4,6-trichlorophenyl)silane, trichloro(2,3,4,6-tetrachlorophenyl)silane, and trichloro(2,3,4,5,6-pentachlorophenyl)silane. The experiments showed that ethylmagnesium bromide does not react with chlorines in the aromatic nucleus. When ar-chlorine-substituted trichlorophenylsilanes react with ethylmagnesium bromide under the conditions described above, the chlorine on the silicon atom is replaced by ethyl in accordance with the following scheme:

$$C_2H_5Br + Mg \rightarrow C_2H_5MgBr; \quad (1)$$

$$C_2H_5MgBr + Cl_nC_6H_{5-n}SiCl_3 \rightarrow \begin{matrix} Cl_nC_6H_{5-n} \\ C_2H_5 \end{matrix} \!\!>\!\! SiCl_2. \quad (2)$$

The replacement of halogen by ethyl occurred most readily in trichloro(p-chlorophenyl)silane, dichloro-(p-chlorophenyl)ethylsilane being obtained in about 70% yield. Ethylmagnesium bromide reacted with trichloro(2,4-dichlorophenyl)silane with formation of dichloro(2,4-dichlorophenyl)ethylsilane in 53% yield. Trichloro(2,4,6-trichlorophenyl)silane gave dichloroethyl(2,4,6-trichlorophenyl)silane in 41% yield. Trichloro-(tetra- and penta-chlorophenyl)silanes exchange the chlorine attached to silicon for ethyl much less readily than the mono-, di-, and tri-chlorophenyl compounds.

As a result of the above-described reaction, some new ar-chlorine-substituted dichloroethylphenylsilanes were prepared. Some of their physical properties are given in the table.

EXPERIMENTAL

The ar-chlorine-substituted trichlorophenylsilanes used in the synthesis of ar-chlorine-substituted dichloroethylphenylsilanes were prepared by the chlorination of trichlorophenylsilane, the following procedure being adopted. A mixture of 211 g (1 mole) of trichlorophenylsilane and 1.05 g (0.5% on the weight of the silicon compound) of anhydrous ferric chloride was prepared in a three-necked flask fitted with thermometer, stirrer, and reflux condenser. The mixture was heated to 60°, and chlorine was then passed into the flask at a rate of 0.1-0.2 liter per minute. The course of the chlorination was checked by determining the change in density. During the process the temperature was maintained at 70-80°. Chlorination continued for 10-15 hours. Vacuum fractionation of the reaction product gave trichloro(p-chlorophenyl)silane, b.p. 90-95° (10 mm), d_{20}^{20} 1.4102; trichloro(2,4-dichlorophenyl)silane, b.p. 105-110° (10 mm), d_{20}^{20} 4801; and trichloro(2,4,6-trichlorophenyl)silane, b.p. 123-125° (10 mm), d_{20}^{20} 1.5530.

As the result of still further chlorination we isolated trichloro(2,3,4,6-tetrachlorophenyl)silane, b.p. 135-137° (10 mm), d_{20}^{20} 1.6210, and trichloro(2,3,4,5,6-pentachlorophenyl)silane, b.p. 147-150° (10 mm).

1. Preparation of Dichloro(p-chlorophenyl)ethylsilane. Magnesium turnings (24 g, i.e. 1 mole) were warmed to 36-38° in a three-necked flask fitted with thermometer, stirrer, dropping funnel, and reflux condenser, and 20 g of a mixture of ethyl bromide and ether was dropped in. Reaction soon set in. A mixture of 246 g (1 mole) of trichloro(p-chlorophenyl)silane, 110 g (1 mole) of ethyl bromide, and 100 g of toluene was then added gradually from the funnel, the reaction mixture being stirred vigorously throughout the addition. The reaction temperature was maintained at 38-40°, this being effected by control of the rate at which the addition was made and by periodic cooling of the reaction flask. When the addition was complete, the reaction mixture was heated at 70-80° for two hours with vigorous stirring. The mixture was cooled and was then filtered directly into a distilling flask fitted with a Vigreux column. The precipitate was washed with toluene (weight 135 g). The liquid phase of the reaction product was fractionally distilled; first toluene came over, and then the dichloro(p-chlorophenyl)ethylsilane fraction was separated at reduced pressure, b.p. 116-118° (7 mm), n_D^{20} 1.5270, and d_{20}^{20} 1.2947. The yield was 168 g (70.3%).

	Found %	C	39.51;	38.80;	H	3.73;	3.63;	Si	10.65;	10.41;	Cl	44.8;	44.4
$C_8H_9SiCl_3$	Calculated %	C	40.14;		H	3.78		Si	11.72;		Cl	44.4	

2. Preparation of Dichloro(2,4-dichlorophenyl)ethylsilane. The reaction conditions were the same as those used in the preparation of dichloro(p-chlorophenyl)ethylsilane. Magnesium turnings (12 g, i.e. 0.5 mole) were warmed to 36-38° in the reaction flask and 20 g of a mixture of ethyl bromide and ether was added. A mixture of 140.2 g (0.5 mole) of trichloro(2,4-dichlorophenyl)silane, 55 g (0.5 mole) of ethyl bromide, and 100 g of toluene was then added from the funnel. When the addition was complete, the

reaction mixture was stirred for two hours at 70-80°, and was then cooled, filtered, and fractionated. The product isolated, amounting to 72.5 g (53.7%), was dichloro(2,4-dichlorophenyl)ethylsilane, b.p. 130-132° (10 mm), n_D^{20} 1.5450, and d_{20}^{20} 1.4381.

	Found %:	C	35.86;	35.96;	H	2.95;	2.93;	Si	9.70; 9.59;	Cl 51.9; 51.7
$C_8H_8SiCl_4$.	Calculated %:	C	35.06;		H	2.92;		Si	10.22;	Cl 51.8

3. Preparation of Dichloroethyl(2,4,6-trichlorophenyl)silane. The reaction conditions were the same as those used in the preceding experiments. Magnesium turnings (12 g, i.e. 0.5 mole) were warmed to 36-38° in the reaction flask and 20 g of a mixture of ethyl bromide and ether was added. A mixture of 157.3 g (0.5 mole) of trichloro(2,4,6-trichlorophenyl)silane, 55 g (0.5 mole) of ethyl bromide, and 100 g of toluene was then added. When the addition was complete, the mixture was heated for two hours at 70-80° with vigorous stirring, cooled, filtered, and fractionated. The product, amounting to 63.2 g (41%), was dichloroethyl(2,4,6-trichlorophenyl)silane, b.p. 142-144° (12 mm), n_D^{20} 1.5481, and d_{20}^{20} 1.4921.

	Found %:	C	31.1;	31.5;	H	2.72;	2.63;	Si	9.63; 9.43;	Cl 56.9; 57.0
$C_8H_7SiCl_5$.	Calculated %:	C	31.14;		H	2.27;		Si	9.07;	Cl 57.5.

4. Preparation of Dichloroethyl(2,3,4,6-tetrachlorophenyl)silane. The reaction conditions were the same as those used in the preceding experiments. Magnesium turnings (12 g, i.e. 0.5 mole) were placed in the flask, 20 g of a mixture of ethyl bromide and ether was added, and then a mixture of 175 g (0.5 mole) trichloro(2,3,4,6-tetrachlorophenyl)silane, 55 g (0.5 mole) ethyl bromide, and 100 g toluene was added. When addition was complete, mixture was heated for 2 hours, cooled, and filtered. Toluene was distilled off, and the residue fractionated. The product, 51.4 g (30%), was dichloroethyl(2,3,4,6-tetrachlorphenyl)silane, b.p. 123-125° (3 mm), n_D^{20} 1.5618; d_{20}^{20} 1.5396.

	Found %:	C	26.96;	27.03;	H	2.22;	2.18;	Si	8.33; 8.09;	Cl 61.72 61.82
$C_8H_6SiCl_6$.	Calculated %:	C	28.01;		H	1.75;		Si	8.17;	Cl 62.0

5. Preparation of Dichloroethyl(2,3,4,5,6-pentachlorophenyl)silane. The reaction conditions were similar to those used in the preceding experiments. Magnesium turnings (2 g, i.e. 0.08 mole) were warmed to 36-38° in the reaction flask, and 2 g of a mixture of ethyl bromide and ether was then added. After this "starter", a mixture of 30 g (0.08 mole) of trichloro(2,3,4,5,6-pentachlorophenyl) silane, 10 g (0.08 mole) of ethyl bromide, and 30 g of toluene was added. When the addition was complete, the reaction mixture was stirred at 70-80° for two hours, cooled, and filtered. Toluene was distilled off, and the residue was fractionated. The product, amounting to 7 g (23%), was dichloroethyl(2,3,4,5,6-pentachlorophenyl)silane, b.p. 145-147° (3 mm), n_D^{20} 1.5650; d_{20}^{20} 1.5996.

	Found %:	C	27.38;	27.35;	H	2.16;	2.35;	Si	7.47; 7.74;	Cl 63.25; 63.62
$C_8H_5SiCl_7$.	Calculated %:	C	25.45;		H	1.32;		Si	7.42;	Cl 65.79

SUMMARY

1. The reaction between ethylmagnesium bromide and ar-chlorine-substituted trichlorophenylsilanes was studied.

2. The following new compounds were prepared: dichloro(p-chlorophenyl)ethylsilane, dichloro(2,4-dichlorophenyl)ethylsilane, dichloroethyl(2,4,6-trichlorophenyl)silane, dichloroethyl(2,3,4,6-tetrachlorophenyl)silane, and dichloroethyl(2,3,4,5,6-pentachlorophenyl)silane.

WURTZ SYNTHESIS OF ORGANOSILICON COMPOUNDS HAVING A DOUBLE BOND IN THE α-POSITION

A. D. Petrov, V. F. Mironov, and V. G. Glukhovtsev

Sodium has been applied successfully in the synthesis of aromatic and aliphatic-aromatic silanes from $SiCl_4$ or R_nSiCl_{4-n} and ArX [1], but the applicability of this reaction to the synthesis of aliphatic silanes was found to be limited owing to the fact that low yields were often obtained. For example, tetraethylsilane is obtained in low yield by this reaction, and tetraallylsilane is not formed at all [2].

Until recently, vinyl halides and their derivatives have not been applied in the Wurtz reaction. The preparation of organosilicon compounds having a double bond in the α-position with respect to silicon has been effected by direct synthesis [3], by elimination of HCl from chlorinated organosilicon compounds [3-5], by addition of $HSiCl_3$ to acetylenic hydrocarbons [6], and in other ways.

These compounds were not synthesized by the organometallic method because, with the exception of β-bromostyrene, vinyl halides and their derivatives could not be converted sufficiently simply and in good yield into Mg, Li, or Na derivatives. Only recently was it found that 2-methylpropenyl bromide [7] and isopropenyl bromide [8] form organolithium compounds of adequate stability, and these were applied by Petrov and Nikishin [8] in the synthesis of a series of 1-alkenylsilanes.

Finally, in 1953 Kanazashi [9] condensed various chloroalkylsilanes with vinyl chloride with the aid of sodium activated by ethyl acetate. He prepared dimethyldivinylsilane and a series of trialkyl(or aryl)vinylsilanes. In the present investigation we found that Kanazashi's procedure is general for the condensation of chlorosilanes not only with vinyl chloride, but also with its derivatives, i.e. compounds having the grouping $>C=CCl$. It must be pointed out that our attempts to carry out the reaction with compounds of the type of allyl and 2-propynyl chlorides were not successful. Condensation of vinyl chloride with $SiCl_4$, even with the latter in excess, gave only one product, tetravinylsilane; no chlorovinylsilanes could be isolated. From 2-methylpropenyl and propenyl bromides we synthesized ethyldimethyl(2-methylpropenyl)silane and ethyldimethylpropenylsilane respectively:

$$(CH_3)_2C{=}CHBr + ClSi(CH_3)_2C_2H_5 \xrightarrow{Na} (CH_3)_2C{=}CHSi(CH_3)_2C_2H_5;$$

$$CH_3CH{=}CHBr + ClSi(CH_3)_2C_2H_5 \xrightarrow{Na} CH_3CH{=}CHSi(CH_3)_2C_2H_5.$$

The preparation of compounds of this type by the Wurtz reaction is simpler than the organolithium synthesis and does not require excess of the alkenyl bromide [8]. By reaction of (1-chlorovinyl)- and (2-chlorovinyl)-trimethylsilanes with $(CH_3)_3SiCl$, good yields were obtained of 1,1- and 1,2-bistrimethylsilylethylenes, i.e. 2,2,4,4-tetramethyl-3-methylene-2,4-disilapentane and 2,2,5,5-tetramethyl-2,5-disilahex-3-ene:

$$(CH_3)_3SiCCl{=}CH_2 + ClSi(CH_3)_3 \xrightarrow{Na} (CH_3)_3Si\underset{\displaystyle CH_2}{\overset{\displaystyle |}{C}}Si(CH_3)_3;$$

$$(CH_3)_3SiCH{=}CHCl + ClSi(CH_3)_3 \xrightarrow{Na} (CH_3)_3SiCH{=}CHSi(CH_3)_3.$$

Finally, from 3-chloro-3-methylallyl alcohol (3-chloro-2-buten-1-ol), which is readily prepared from 1,3-dichloro-2-butene, 3-(trialkylsilyl)-2-buten-1-ols were prepared by the reactions given below (R = CH_3 and C_2H_5):

These first unsaturated organosilicon alcohols are readily cyanoethylated with acrylonitrile. The fact that, under the conditions of the Wurtz synthesis, tetravinylsilane is obtained in 65% yield, whereas tetraallylsilane is not obtained at all, is not difficult to understand in view of Petrov and Shchukovskaya's recent observation [10] that phenyllithium breaks the Si–C link in allyltriphenylsilane. It is evident that allylsodium formed under the conditions of the Wurtz synthesis, also breaks the Si–C link in tetraallylsilane.

* Prepared for the first time.

The synthesis of tetraallylsilane has enabled us to establish that, unlike allyl [11], vinyl attached to silicon does not show exaltation of molecular refraction. A comparison of the Raman spectra of tetravinylsilane and triethylvinylsilane enabled the most characteristic frequencies of vinyl attached to silicon to be determined; 1272, 1404, 1594, and 3054 cm^{-1}. It was found also that the intensities of these lines increase in proportion to the number of vinyl groups, i.e. for $(CH_2{=}CH)_4Si$ they are four times as intense as for $(C_2H_5)_3SiCH{=}CH_2$. Similar behavior was observed previously for allylsilanes [11]*. It is interesting also to note that tetravinylsilane combines more slowly than $(C_2H_5)_3SiCH{=}CH_2$ with thiocyanogen.

The table gives the properties both of compounds prepared previously but now characterized in greater detail and also of compounds now synthesized for the first time.

EXPERIMENTAL

Tetravinylsilane $(CH_2{=}CH)_4Si$ (I). Sodium (140 g) was melted under 500 ml of toluene in a one-liter flask fitted with reflux condenser, dropping funnel, tube reaching to the bottom for the passage of gas, and stirrer. The sodium was converted into the state of dust by rapid rotation of the stirrer. The toluene was cooled and decanted from the sodium, and 300 ml of ether and 250 g of $SiCl_4$ were introduced into the flask. Ethyl acetate (3-5 ml) was then added, and vinyl chloride (dried with phosphoric oxide) was passed through the stirred mixture so that the ether boiled gently. After seven hours, the precipitate was filtered off, ether was distilled from the filtrate, and the residue was vacuum-distilled (b.p. 66-68° at 90 mm). Redistillation through a column gave 70 g of (I), b.p. 120-130°, in 65% yield.

	Found %	C	70.49;	70.71;	H	8.91;	8.92;	Si 20.82; 20.71
$C_8H_{12}Si$.	Calculated %	C	70.52;		H	8.88;		Si 20.60

$\Delta\nu$: 305(20b), 343(15), 584(35), 734(5), 962(12), 1010(12b), 1271(90), 1404(150), 1594(160), 2846(15), 2950(35), 2674(325), 3009(20), 3054(125).

Chlorination of $C_2H_5SiCl_3$, $ClCH_2CH_2SiCl_3$ (II), $CH_3ClCHSiCl_3$ (III), and $Cl_3SiCHSiCl_3$. Chlorination was carried out under ultraviolet irradiation under the conditions described previously [12]; it appeared to proceed in the liquid phase since liquid-drop condensation of the substance being chlorinated occurred in the reaction zone. In the chlorination of 2 kg of $C_2H_5SiCl_3$, a 93% yield was obtained of the compounds (II) and (III) in the proportions 1 : 1.5. In the chlorination of (III) at a temperature in the flask of up to 152°, an 89% yield was obtained of trichloro(1,1-dichloroethyl)silane (IV) and trichloro(1,2-dichloroethyl)silane (V) in the proportions 1 : 0.6. The chlorination of (II) at temperatures ranging up to 174° gave a difficultly separable mixture of (V) and trichloro(2,2-dichloroethyl)silane (VI), b.p. 170-180°, in 93% yield. The chlorination of $Cl_3SiCHSiCl_3$ (CH_3) gave a 44% yield of $Cl_3SiCClSiCl_3$ (CH_3) (VII), b.p. 199-200°.

	Found %	C	7.43;	7.24;	H	0.98;	0.91;	Si 17.47; 16.93; Cl 73.83; 73.83
$C_2H_3Si_2Cl_7$.	Calculated %	C	7.27;		H	0.61;		Si 16.99; Cl 75.12

The elimination of HCl from (IV), (V), the mixture of (V) and (VI), and (VII) was carried out by distilling them with quinoline [5] or with diethyl- or dimethyl-aniline and then redistilling the distillate through a column. It is more convenient to use diethyl- or dimethyl-aniline rather than quinoline, since these compounds do not form volatile salts that cause breakages in the apparatus and do not give solid residues that are difficult to remove from the flask. The mixture of (V) and (VI) gave a 60% yield of $Cl_2SiCH{=}CHCl$ (VIII) and $Cl_2SiCCl{=}CH_2$ (IX) in the proportions 1 : 1.3.

(1-Chlorovinyl) trimethylsilane [5] $CH_2{=}ClCSi(CH_3)_3$ (X). The compound (IX) (100 g) was added over a period of an hour to CH_3MgI prepared from 45 g of Mg and 350 g of CH_3I in 500 ml

*The spectra were determined and interpreted by Yu. P. Egorov.

of ether. The mixture was boiled for five hours, and on the next day it was decomposed with water. Ether was removed from the ether layer, and distillation of the residue through a column gave 42 g (61.5%) of the compound (X), b.p. 104°. Color due to the presence of iodine was removed by means of aqueous sodium sulfite solution.

(2-Chlorovinyl) trimethylsilane $ClCH=CHSi(CH_3)_3$ (XI). The compound (VIII) (48 g) was added over a period of two hours to CH_3MgI prepared from 18.5 g of Mg and 140 g of CH_3I in 500 ml of ether. The mixture was boiled for five hours, and the usual treatment and distillation through a column gave 25 g (77%) of the compound (XI), b.p. 114-116°.

	Found %:	C	44.73;	44.6;	H	8.33;	8.30;	Si	20.63; 20.45; Cl 26.80; 25.70
$C_5H_{11}SiCl$.	Calculated %:	C	44.59;		H	8.31;		Si	20.83; Cl 26.33

(1-Chlorovinyl) triethylsilane $CH_2=ClCSi(C_2H_5)_3$ (XII). The compound (IX) (189 g) was added to C_2H_5MgBr prepared from 77 g of Mg and 420 g of C_2H_5Br in 1500 ml of ether. On the next day, after a two-hour boil and the usual treatment, 133 g (78.5%) of the substance (XII), b.p. 183°, was obtained.

	Found %:	C	54.06;	54.10;	H	9.63;	9.64;	Si	16.14; 15.97
$C_8H_{17}SiCl$.	Calculated %:	C	54.36;		H	9.69;		Si	15.87

2,2,4,4-Tetramethyl-3-methylene-2,4-disilapentane $[(CH_3)_2Si]_2C=CH_2$ (XIII). Sodium (9 g) was melted under 30 ml of toluene and converted by stirring into fine dust. The mixture was cooled, and 500 ml of ether, 20 g of $(CH_3)_2SiCl$, 1.2 ml of (X), and 1.2 ml of ethyl acetate were added. When reaction had set in, 23.5 g of (X) was added at such a rate that the ether boiled gently. The mixture was then heated for 2.5 hours. The precipitate was filtered off, ether was distilled from the filtrate, and the residue was distilled through a column and gave 14 g (46.5%) of (XIII), b.p. 151°.

	Found %:	C	55.97;	55.99;	H	11.50;	11.58;	Si	32.55; 32.67
$C_9H_{22}Si_2$.	Calculated %:	C	55.74;		H	11.69;		Si	32.55

2,2,5,5-Tetramethyl-2,5-disilahex-3-ene $(CH_3)_2SiCH=CHSi(CH_3)_3$ (XIV). Sodium (10 g) was granulated in isooctane, 250 ml of ether was added, and to the suspension so obtained 25 g of $(CH_3)_2SiCl$ and 2 ml of (XI) were added. Reaction was initiated by addition of 1-2 ml of ethyl acetate, and 27 g of (XI) was then added. The mixture was boiled for four hours, and the precipitate formed was filtered off. The product, amounting to 34 g (76%), was the compound (XIV).

	Found %:	C	56.06;	55.99;	H	11.82;	11.69;	Si	32.59; 32.35
$C_9H_{22}Si_2$.	Calculated %:	C	55.74;		H	11.69;		Si	32.55

Ethyldimethyl (2-methylpropenyl) silane $C_2H_5(CH_3)_2SiCH=C(CH_3)_2$ (XV). To 17 g of sodium in 250 ml of ether, 41 g of $C_2H_5(CH_3)_2SiCl$ and 1 ml of ethyl acetate were added. 2-Methylpropenyl bromide (47 g) was then added gradually. The usual treatment gave 23.8 g (50.1%) of (XV).

	Found %:	C	67.74;	67.56;	H	12.75;	12.58;	Si	19.71; 19.54
$C_8H_{18}Si$.	Calculated %:	C	67.52;		H	12.75;		Si	19.72

Ethyldimethylpropenylsilane $C_2H_5(CH_3)_2SiCH=CHCH_3$ (XVI). To 17 g of sodium in 250 ml of ether, 41 g of $C_2H_5(CH_3)_2SiCl$ and 1 ml of ethyl acetate were added. Propenyl bromide (47 g) was added in portions. The usual treatment gave 14 g (32.5%) of (XVI), b.p. 114.5-119.5°.

	Found %:	C	65.72;	65.70;	H	12.30;	12.28;	Si	22.37; 22.04
$C_7H_{16}Si$.	Calculated %:	C	65.54;		H	12.57;		Si	21.87

(3-Chloro-2-butenyloxy) trimethylsilane $CH_3C(Cl)=CHCH_2OSi(CH_3)_3$ (XVII).

A mixture of 52 g of $(CH_3)_3SiCl$ and 39 g of 3-chloro-2-buten-1-ol was boiled for four hours until HCl ceased to separate. Distillation through a column gave 33 g (50.8%) of (XVII), b.p. 162-165°.

	Found %:	C	46.54;	46.69;	H	8.08;	8.29		
$C_7H_{15}SiOCl$.	Calculated %:	C	47.00;		H	8.45			

(3-Chloro-2-butenyloxy)triethylsilane $CH_3C(Cl)=CHCH_2OSi(C_2H_5)_3$ (XVIII).

3-Chloro-2-buten-1-ol (109 g) was added to a stirred mixture of 142 g of $(C_2H_5)_3SiCl$, 80 g of pyridine, and 250 ml of benzene. After two days the precipitate of pyridine hydrochloride was filtered off. Fractionation of the filtrate gave 142 g (82.5%) of (XVIII), b.p. 70-72° (2 mm).

	Found %:	C	53.80;	53.85;	H	9.38;	9.36;	Cl	16.33;	16.62;	Si	12.09;	11.5
$C_{10}H_{21}SiOCl$	Calculated %:	C	54.39;		H	9.59;		Cl	16.06;		Si	12.70	

2,2,6,7,7-Pentamethyl-3-oxa-2,7-disilaoct-5-ene $(CH_3)_3SiC(CH_3)=CHCH_2OSi(CH_3)_3$ (XIX).

Reaction was initiated in a mixture of 8 g of sodium, 200 ml of ether, and 21 g of $(CH_3)_3SiCl$ by addition of ethyl acetate, and 28.5 g of (XVII) was then added over a period of two hours. A three-hour boil followed by the usual treatment gave 18 g (52%) of (XIX), b.p. 195°.

	Found %:	C	55.35;	55.42;	H	10.97;	11.14;	Si	25.77;	25.68
$C_{10}H_{24}Si_2O$	Calculated %:	C	55.58;		H	11.11;		Si	25.93	

3,3,8,8-Tetraethyl-7-methyl-4-oxa-3,8-disiladec-6-ene $(C_2H_5)_3SiC(CH_3)=CHCH_2OSi(C_2H_5)_3$ (XX).

To a mixture of 25.5 g of sodium, 500 ml of ether, and 85 g of $(C_2H_5)_3SiCl$, 120 g of (XVIII) was added. The precipitate was filtered off on the next day, and distillation gave 85 g (52%) of (XX), b.p. 101° (2 mm).

	Found %:	C	62.95;	62.90;	H	11.98;	12.12;	Si	18.15;	18.39
$C_{16}H_{36}Si_2O$	Calculated %:	C	63.94;		H	12.04;		Si	18.07	

3-(Trimethylsilyl)-2-buten-1-ol $(CH_3)_3SiC(CH_3)=CHCH_2OH$ (XXI). A mixture of 16 g of (XIX), 20 ml of ethanol, 30 ml of water, and four drops of hydrochloric acid was boiled for eight hours. The product was dried with sodium sulfate and fractionated, when 5 g (60%) of (XXI), b.p. 45-47° (2 mm), was obtained.

	Found %:	C	58.24;	58.28;	H	11.27;	11.11	Si	19.66;	19.54
$C_7H_{16}SiO$	Calculated %:	C	58.30;		H	11.19;		Si	19.42	

3-(Triethylsilyl)-2-buten-1-ol $(C_2H_5)_3SiC(CH_3)=CHCH_2OH$ (XXII). A mixture of 77 g of (XX), 100 ml of ethanol, 23 ml of water, and 3 ml of hydrochloric acid was boiled for three hours. On the next day the mixture was dried and fractionated, when 25 g (59%) of (XXII), b.p. 81° (2 mm), was obtained.

	Found %:	C	63.58;	63.58;	H	11.93;	12.01;	Si	15.78;	15.73
$C_{12}H_{28}SiO$	Calculated %:	C	64.45;		H	11.91;		Si	15.05	

In presence of sodium methoxide, (XXII) combined with acrylonitrile with evolution of heat. The addition product was obtained in 85% yield.

	Found %:	C	65.44;	65.33;	H	10.69;	10.54;	Si	11.69;	11.41
$C_{15}H_{29}SiOH$	Calculated %:	C	65.21;		H	10.52;		Si	11.72	

SUMMARY

1. It was shown that organosilicon compounds having a double bond in the α-position with respect to silicon can be synthesized in high yield by the condensation of chlorotrialkylsilanes with vinyl halide derivatives in ether in presence of sodium activated by ethyl acetate.

2. Silicon tetrachloride was condensed with $CH_2=CHCl$, and R_3SiCl was condensed with $CH_2=CHCl$.

and R_3SiCl was condensed with $CH_3CH{=}CHBr$, $(CH_3)_2C{=}CHBr$, $(CH_3)_2SiCH{=}CHCl$, $(CH_3)_2SiOCl{=}CH_2$ and $R_3SiOCH_2CH{=}\underset{\displaystyle CH_3}{\overset{\displaystyle |}{C}}Cl$ (R = CH_3 and C_2H_5).

3. Sixteen organosilicon compounds were prepared for the first time. These included tetravinylsilane and 3-(trialkylsilyl)-2-buten-1-ols.

CATALYTIC HYDROCONDENSATION OF CARBON MONOXIDE WITH OLEFINS

COMMUNICATION 14. INTERCONVERSION OF 1- AND 2-BUTENES UNDER THE CONDITIONS OF CATALYTIC HYDROCONDENSATION OF CARBON MONOXIDE WITH OLEFINS

Ya. T. Eidus and R. I. Izmailov

Apart from deuteropropene, the normal butenes are the simplest olefins capable of undergoing isomerization by displacement of the double bond (interconversion of 1- and 2-butenes). These transformations can occur at the actual moment when the butene is formed, e.g. in the dehydration of butanols, the dehydrogenation of butane, the dimerization of ethylene, and other such processes, and also when it is formed intermediately in other reactions.

The interconvension of 1- and 2-butenes is not only of theoretical, but also of practical interest, since in any process one of the isomers may be preferable to the other as starting material [1]. The purely thermal isomerization of the butenes by double-bond displacement occurs at comparatively high temperatures - of the order of 600-650° [2]. A claim made in a patent [3], according to which 1-butene undergoes 87% conversion into 2-butene at 550° in an empty quartz tube, is not very probable since the content of 1-butene in the equilibrium mixture of butenes at this temperature is not more than 35% [4]. At lower temperatures displacement of the double bond can occur only in presence of catalysts. No isomerization of 2-butene into 1-butene was observed at 390°, although cis-trans interconversion proceeded at an appreciable rate [5]. The displacement of the double bond in butenes, occurring in the substances as such or occurring at the moment of their formation, particularly from butanols, has been investigated over various catalysts, of which the most active were found to be, on the one hand, acidic catalysts - sulfuric [6] and phosphoric [6-10] acids, as such or supported on solid carriers, phosphoric oxide [8], aluminum sulfate [7, 8, 11], aluminum phosphate [6], silica gel [7], alumina, apparently when containing acidic impurities [7, 12-15], and natural and synthetic aluminosilicates [16-19] - and, on the other hand, metals and their oxides - ThO_2 [20], Co–Cu–ThO_2 [12], Co on charcoal [21], and metallic nickel [22, 23]. It must be pointed out that reaction over metallic nickel occurs only in the presence of hydrogen [22]. The dimerization of ethylene at 35-40° and 50 atm over cobalt deposited on charcoal yielded a mixture of 1- and 2-butenes, and the relative amount of 1-butene fell as the space velocity of the ethylene was lowered, which indicates that the 1-butene formed initially was isomerized into 2-butene. Over the catalyst Co–Cu–ThO_2, which is active in the synthesis of hydrocarbons from carbon monoxide and hydrogen, the treatment of 1-butene at 190° and atmospheric pressure gave a gas containing 34% of 2-butene [12]. When the reaction products were again passed over the catalyst, the outgoing gas already contained 53% of 2-butene. In a similar experiment with cis-2-butene, the outgoing gas contained 7% of 1-butene. In experiments lasting 20-24 hours in a circulating system, equilibrium was attained when the original gas was cis-2-butene or a mixture containing 13.8% of 1-butene. The equilibrium mixture contained 11.3% of 1-butene, 31.0% of cis-2-butene, and 57.7% of trans-2-butene; no isobutene was formed. However, over a catalyst that had not been regenerated practically no displacement of the double bond occurred.

The present investigation had the object of determining the possibility of the isomerization of 1-butene into 2-butene, and of the reverse reaction, under the conditions required for the catalytic hydrocondensation of carbon monoxide with olefins [24]. This question has a direct bearing on a previous investigation on the hydrocondensation of carbon monoxide with butene obtained by the dehydration of 1-butanol over alumina at

400° [25] and also on the view that the formation of hydrocarbon chains in the hydrocondensation of carbon monoxide with ethylene and propene proceeds stepwise, and therefore with the intermediate formation of butene. In order to resolve this question, an investigation was made of the behavior of 1- and 2-butenes over a catalyst for the reaction of hydrocondensation at atmospheric pressure and 190° in absence and in presence of hydrogen, but always in absence of carbon monoxide.

EXPERIMENTAL

The determination of the composition of the mixture of butenes was one of the most complicated tasks arising in the investigation of the isomerization of butenes. Analytical errors give rise to numerous discrepancies between the results obtained by different authors. Various methods based on the bromination of the mixture of butenes, which have been used previously [6, 13, 17], were found to be inaccurate owing to the possibility of the thermal isomerization of the dibromides during fractionation. Low-temperature fractionation of butenes through a Podbielniak column [6, 7, 12, 15], supplemented by the usual gas analysis of the fractions [7, 12], is also inadequate. A simple, rapid method of determining the composition of a liquid mixture of normal butenes is the measurement of its vapor pressure at −80° [22] or 0° [26].

We used a combined method for the determination of mixtures of butenes; it included low-temperature fractionation through a Podbielniak column, sulfuric acid analysis of the fractions supplemented by a test for isobutene with the Deniges reagent, and determination of the vapor pressures of the liquefied fractions at 0°. In calculating the composition of mixtures from vapor pressures we used Raoult's law. The linearity of the relationship between vapor pressure and molar composition has been shown previously [19]. The probable error in the method based on vapor pressure at 0° is less than 1%. Vapor pressures at 0° P_0 are as follows [26]: isobutene 988.4 ± 0.6 mm, 1-butene 964 ± 1 mm, trans-2-butene 733.6 ± 0.3 mm, cis-2-butene 660 ± 1.5 mm, and butane 775 mm [27].

Preparation of 1-Butene

Freshly prepared butyl alcohol - b.p. 116.5-117.0° (756 mm), n_D^{20} 1.3991, d_4^{20} 0.8098; found MR 22.13; calculated for C_4H_9OH MR 22.20 (the literature [28, 29] gives n_D^{20} 1.3992, d_4^{20} 0.80978) - was dehydrated over commercial alumina at 390°. The resulting gas was dried over calcium chloride and frozen out with a mixture of solid carbon dioxide and acetone. In order to enrich it in 1-butene, the liquid butene was fractionated through a Podbielniak low-temperature column, the distillate being collected from −6.2° upwards. The result of such a fractionation (23 ml of liquid butene) is given in Table 1.

TABLE 1

Fraction	Boiling limits (°C)	Yield of fraction (liters of gas)	Vapor pressure at 0° P_0 (mm)	1-Butene content (%)	2-Butene content (%)
I*	From −6.2 to −6 (inclusive)	5.4	952	95.5	4.5
II	From −6 to +0.8	1.0	880	55.5	44.5
III	From +0.8 to +3	0.65	782	21.3	78.7

Refractionation of Fraction I through the same column gave a narrow fraction of b.p. −6° and P_0 962.5 mm, which corresponds to 92.4% of 1-butene and 0.6% of 2-butene; it comprised about 60% of Fraction I and about 45% of the original butene. In other batches treated in this way we succeeded in obtaining 1-butene having P_0 964 mm.

* Fraction I contained about 0.4% of isobutene.

Preparation of 2-Butene

2-Butene was prepared from 2-butanol by dehydration over alumina at 340°. The 2-butanol was prepared by the hydrogenation of 2-butanone, and it was distilled through a 40-plate column before use; it then had b.p. 99.2° (758 mm), n_D^{20} 1.3970, d_4^{20} 0.8068, found MR 22.11; calculated for C_4H_9OH MR 22.20 (the literature [30] gives n_D^{20} 1.39780, [31] 1.3973 [32], d_4^{20} 0.8063 [29], 0.80652 [33], b.p. 99.5° (760 mm), [34] 99.53°). The butene so obtained contained 99% of normal butenes and about 1% of isobutene; when liquefied it had P_0 775 mm.

The liquid butene (175 ml) was fractionated through the low-temperature column, and 6 liters of gas (13.7%) came over from −42° to +0.8° (up to −4°, 2.5 liters came over; from −4° to −1°, 1.5 liters; from −1° to +0.2°, 1 liter; and from +0.2° to +0.8°, 1 liter). This fraction (b.p. from −42° to +0.8°) had P_0 1050 mm. The whole of the residue (86.3%) was fractionated through the same column over the range 0.8-4° into five different fractions, each consisting of 30 ml of liquid, and having P_0 = 748, 743, 732.8, 729.8, and 728 mm respectively. The last fraction (P_0 = 731 mm), which contained neither 1-butene nor isobutene, was taken for the experiments.

In all of the experiments the catalysts (30 ml each) were taken from the same preparation; before use they were treated with hydrogen at 450°. Their activity in the reaction of hydrocondensation of carbon monoxide with olefins, which was tested with a gas mixture consisting of 70% C_2H_4, 5% CO, and 25% H_2 at 190° and at a space velocity of 100 hour^{-1}, may be expressed by the yield of hydrocarbons, which was about 500 ml per cu.m. After the isomerization experiments the catalysts preserved their activity for the hydrocondensation reaction. The experiments were carried out in a glass tube 12 mm in diameter.

1) In Absence of Hydrogen (Experiment 287, Catalyst 64). In order to remove hydrogen completely from the surface of the catalyst, nitrogen was displaced at 190°, and 1-butene (P_0 964 mm) was passed for two hours at a space velocity of 70 hour^{-1}. The volume passed was 4200 ml, and 2800 ml of gas was recovered having P_0 924 mm and a composition of 98.6% n-C_4H_8 and 1.4% C_4H_{10}, which corresponds to 83.3% of 1-butene, 15.3% of 2-butene, and 1.4% of butane*. Under the same conditions a further 2630 ml of the same 1-butene was passed, and 2600 ml of gas was recovered having P_0 953 mm and a composition of 100% of n-butene; finally a further 2100 ml of 1-butene was passed and 2100 ml of gas was recovered having P_0 953 mm and a composition of 100% of n-butene. Both of the last two portions of gas obtained by passage of 1-butene over the catalyst had the composition of 95.8% of 1-butene and 4.2% of 2-butene**. Thus, in absence of hydrogen 1-butene undergoes very little isomerization (about 4%); when hydrogen is present in the catalyst but not in the original gas, 1-butene isomerizes to the extent of about 15%.

2) In Presence of Hydrogen (Experiment 288, Catalyst 65). A gaseous mixture consisting of 90.1% of 1-butene (P_0 962.5 mm, corresponding to 0.6% of 2-butene) and 9.9% of hydrogen was passed at 190° over Catalyst 65 at a space velocity of 66 hour^{-1}. The volume passed was 7700 ml, including 6900 ml of butene and 760 ml of hydrogen. The outgoing gas was frozen out at −70°, 225 ml of gas not being condensed at this temperature (8.2% C_2H_4 + 91.8% H_2 + CH_4 + C_2H_6). About 15 ml of liquid was condensed, and on evaporation this gave 3700 ml of gas of composition 0.4% of isobutene, 90.5% C_nH_{2n} and 9.1% C_nH_{2n+2}. The condensate was fractionated through a Podbielniak column, and the part boiling below the butenes (from −105° to −30°), which comprised 4.4% of the condensate, had the composition 16.5% C_2H_4, 22.0% C_3H_6, and 61.5% C_nH_{2n+2} ($n < 4$). The fractionation curve for this part of the condensate is shown in Fig. 1.

From the curve in Fig. 1 it can be calculated that $C_2H_4 : C_2H_6 : C_3H_6 = 1.0 : 1.1 : 1.5$. The second row of figures along the axis of abscissae in Fig. 1 give the percentage of the whole condensate. The remaining 95.6% of the condensate formed the C_4 fraction and had the following composition: 0.4% of isobutene, 90.9%

---

* Calculated for the formation of an equilibrium mixture of cis- and trans-2-butenes. When calculated for trans-2-butene, 16.2% of 2-butene is obtained instead of 15.3%.

** Calculated for an equilibrium mixture of the two forms of 2-butene; when calculated for trans-2-butene a composition of 95.8% of 1-butene and 4.2% of 2-butene is obtained.

Fig. 1. Fractionation curve for products boiling below the butenes formed in the isomerization of 1-butene (Experiment 288)

Fig. 2. Fractionation curve for the C_4 fraction of products formed in the isomerization of 1-butene (Experiment 288)

of n-butenes, and 8.7% of butane. The C_4 fraction of the reaction product was fractionated through the same column. The results of the fractionation are give in Table 2. The contents of 1- and 2-butenes were calculated from the vapor pressures P_0, taking into account the contents of butane, isobutene, and n-butenes found by gas analysis.

TABLE 2

Fraction	Boiling limits (°C)	Yield of fraction (% on original C_4 fraction)	Vapor pressure at 0° P_0 (mm)	1-Butene content		2-Butene content		Isobutene content		Butane content	
				(%)	(ml of gas)	(%)	(ml of gas)	(%)	(ml of gas)	(%)	(ml of gas)
I	−6	26	970	97	883	–	–	0.6	5.5	2.4	22
II	From −6 to −0.7	28	877	59.4	582	23.2	227	–	–	17.4	171
III	From −0.7 to +3	46	725	–	–	89.1	1434	–	–	10.9	176

The fractionation curve for the C_4 fraction is shown in Fig. 2. No residue corresponding to C_5 hydrocarbons and hydrocarbons of still higher-boiling point was obtained.

It follows from Table 2 that the C_4 fraction of the product of the isomerization of 1-butene in presence of 10% of hydrogen had the following composition: 41.9% of 1-butene, 47.5% of 2-butene, 10.4% of butane, and 0.2% of isobutene. From the data on the composition and P_0 of Fraction III, which contained the bulk of the 2-butene (86%), it was found that the relative amounts of cis- and trans-2-butenes in this fraction was 1 : 4.3.

Hence, the isomeric transformation of 1-butene into 2-butene occurs at 190° in presence of 10% of hydrogen. At a space velocity of 66 $hour^{-1}$ a mixture was obtained in which the relative amounts of 1- and 2-butenes were 1 : 1.1, the equilibrium ratio at 190° being 10.8 : 89.2 [4]. The relative amounts of cis- and trans-2-butenes were 1 : 5.1 (equilibrium ratio 29.5 : 59.7 [4]). In the course of the reaction partial hydrogenation occurred. The C_4 fraction contained 10.4% of butane. Hydrogenolysis and skeletal isomerization of 1-butene occurred to a negligible extent.

Fig. 3. Fractionation curve for products obtained in the isomerization of 2-butene (Experiment 291)

Fig. 4. Fractionation curve for products boiling below the butenes formed in the isomerization of 2-butene (Experiment 292)

Experiments on the Isomerization of 2-Butene into 1-Butene

1) In Absence of Hydrogen (Experiment 289, Catalyst 66). Hydrogen was displaced from the reaction tube with nitrogen at 250°, and then 2-butene was passed at 190° with the result that some hydrogenation occurred [the outgoing gas (600 ml) contained 82.7% of butene and 17.3% of butane]. More 2-butene (P_0 731 mm, 96.5% trans and 3.5% cis) was then passed over the catalyst at 190° at a space velocity of 66 hour^{-1}. The volume of gaseous 2-butene that was passed was 3500 ml, and this was recovered almost without change in volume; it contained 100% of 2-butene and after liquefaction had P_0 731.5 mm. Under these conditions, therefore, 2-butene is not isomerized into 1-butene and does not undergo cis-trans isomerization.

Experiment 290. 2-Butene (3700 ml, P_0 731 mm) was passed over the same catalyst at the same space velocity at 230°. The outgoing gas had P_0 739.5 mm after liquefaction and contained 0.7% of isobutene and 99.3% of n-butenes. These results correspond to a 1-butene content of 2.9%. Hence, even at a higher temperature (230°) the extent to which double-bond displacement occurs in 2-butene is very small.

2) In Presence of Hydrogen (Experiment 291, Catalyst 67). A gaseous mixture (7200 ml) of 90% 2-butene (P_0 728 mm, 6.8% cis and 93.2% trans) and 10% hydrogen was passed over the catalyst at 190° and at a space velocity of 69 hour^{-1}. The volume of gas recovered was 3600 ml, the liquefaction of which gave 15 ml of liquid having P_0 881.5 mm and composition: 0.3% of isobutene, 93.2% C_nH_{2n}, and 6.5% C_nH_{2n+2}. This 15 ml was fractionated through a Podbielniak column with the following results: driven off up to −40°, 153 ml of gas (Fraction I), which formed 4.6% of the whole and had the composition 15.2% C_2H_6, 34.9% C_3H_8, and 49.9% C_nH_{2n+2}. The residue (P_0 729.5 mm) was fractionated into two fractions: Fraction II (23 ml of gas), b.p. from −7° to −5°, and Fraction III (3330 ml of gas), b.p. 0-3°. Fraction III did not contain isobutene and consisted of 95.5% of n-butenes and 4.5% of butane. It follows from these data that the overall composition of the condensed gas was 0.75% of ethylene, 1.6% of propene, 4.2% of butane, 90.4% of 2-butene, 2.25% of ethane + propane, and 0.7% of 1-butene + isobutene.

In Experiment 291 not only gas, but also 0.3 ml of liquid condensable at room temperature was obtained, this representing a yield of liquid hydrocarbons of 37.5 ml per cu.m.

Hence, in the study of the displacement of the double bond in 2-butene in presence of 10% of hydrogen at 190°, practically no 1-butene was detected in the reaction products. Partial hydrogenation and hydrogenolysis occurred and, to a very slight extent, also hydropolymerization.

Experiment 292. An isomerization experiment was carried out with the same Catalyst 67 on a mixture of 73.4% of 2-butene (P_0 728 mm) and 26.6% of hydrogen at 190° and a space velocity of 100 hour^{-1}. The volume of gaseous mixture passed was 9000 ml, and the products were 0.5 ml of liquid condensate (50 ml per cu.m), 3750 ml of gas, which condensed to 15 ml of liquid, and 900 ml of gas, which did not condense at −70°

Fig. 5. Fractionation curve for the C_4 fraction from 2-butene (Experiment 292)

and had the composition: 7.2% C_2H_6, 80.1% H_2, and 12.7% $CH_4 + C_2H_6$.

The liquefied gas (3750 ml, 89.0% C_nH_{2n}; 11.0% C_nH_{2n+2}) was fractionated through a Podbielniak column into the following fractions (Figures 4 and 5): Fraction I (163.8 ml, i.e. 4.4% of gas), b.p. from −105° to −40°, composition 7.8% C_3H_6, 29.2% C_3H_8, and 63.0% $C_3H_6 + C_3H_8$ (the residue remaining after removal of Fraction I had P_0 739 mm); Fraction II (23.4 ml, i.e. 0.6%), b.p. from −40° to −2° (not analyzed); and Fraction III (3557 ml, i.e. 95%), b.p. from −2° to +1°, composition 92.0% C_4H_8 and 7.4% C_4H_{10}.

Fig. 4 gives the fractionation curve for Fraction I, Fig. 5 gives the fractionation curve for Fractions II and III.

The condensed gas had the following composition: 0.3% C_2H_6, 1.3% C_3H_6, 0.6% of 1-butene (in admixture with isobutene), 88.0% of 2-butene, 2.8% of $C_2H_6 + C_3H_8$, and 7% of C_4H_{10}. It will be seen from these results that 1-butene is practically absent from the outgoing gas.

TABLE 3

Original gas		Space velocity ($hour^{-1}$)	Composition of C_4 fraction of reaction product (%)			
Butene	Hydrogen (%)		1-Butene	2-Butene	Butane	1-Butene / 2-Butene
1-Butene	0	70	95.8	4.2	—	1 : 0.04
1-Butene	9.9	66	41.9	47.5	10.4	1 : 1.1
2-Butene	0	66	—	100	—	—
2-Butene	10	69	0.7	94.9	4.4	1 : 174
2-Butene	26.6	100	0.7	92.0	7.3	1 : 171

Table 3 gives a general summary of the results obtained on the isomerization of 1-butene into 2-butene and vice versa over a hydrocondensation catalyst at 190°.

It is notable that 1-butene is isomerized into 2-butene in presence of hydrogen, a fact that proves the activity of the catalyst for this reaction. A considerable proportion of the 1-butene remains adsorbed on the catalyst surface; when the initial gas consists entirely of olefin (hydrogen absent), the extent to which it is absorbed is less. It appears that, in presence of hydrogen, 2-butene is isomerized into 1-butene, but this remains adsorbed on the catalyst surface.

SUMMARY

1. The catalytic reaction 1-butene ⇌ 2-butene was studied both in presence and in absence of hydrogen, the conditions being those for the hydrocondensation of carbon monoxide with olefins, carbon monoxide, however, being absent.

2. It was shown that, in absence of hydrogen, the isomerization of 1-butene into 2-butene and vice versa did not occur to an appreciable extent.

3. In presence of 10% of hydrogen, 1-butene was isomerized into 2-butene, the relative amounts of 1- and 2-butenes in the products being 1 : 1.1 (at a space velocity of 66 $hour^{-1}$).

4. In experiments on the isomerization of 2-butenes in presence of 10% and 26.6% of hydrogen at space velocities of 69 and 100 $hour^{-1}$, no appreciable amount of 1-butene could be detected in the reaction product.

5. In experiments with 1-butene, hydrogenation of the olefin proceeded much more rapidly (about twice as fast) than in experiments with 2-butene under similar conditions.

CATALYTIC HYDROCONDENSATION OF CARBON MONOXIDE WITH OLEFINS

COMMUNICATION 15. HYDROCONDENSATION OF CARBON MONOXIDE WITH 2-BUTENE

Ya. T. Eidus and R. I. Izmailov.

In a previous communication [1] we described experiments on the hydrocondensation of carbon monoxide with the butene obtained by dehydration of butyl alcohol over alumina, which consists of a mixture of 1- and 2-butenes, the former predominating. We used an equimolecular mixture of the butene obtained in this way and hydrogen, and 4-6% of carbon monoxide was added. The hydrocondensation reaction gave liquid hydrocarbons in a yield of 635 ml per cu.m, or 55 ml per liter of catalyst per hour. About 30-35% of the olefin that reacted was hydrogenated to butane. After being "debutanized", the liquid condensate boiled over the range 28-276° and contained 28% of olefins; after hydrogenation the following fractions were found (% by volume): about 24% of the C_5 fraction (about half of this was isopentane), 15% of the C_6 fraction, 8% each of the C_7 and C_8 fractions, and 9% of the C_9 fraction.

It was of interest to investigate the behavior of 2-butene in the reaction of hydrocondensation with carbon monoxide, for there were no data on the behavior of symmetrically disubstituted ethylenes in this reaction. When an attempt was made to use cyclohexene - which can be regarded as a symmetrically disubstituted ethylene - in the reaction of hydrocondensation with carbon monoxide [2], it was found that "irreversible" catalysis and hydrogenation to cyclohexane occurred, but methylation with formation of methyl- and 1,2-dimethylcyclohexenes occurred only to a slight extent.

The object of the present investigation was the study of the hydrocondensation of carbon monoxide with 2-butene. The apparatus and experimental procedure were the same as in previous work [1]. The preparation of pure 2-butene for use as a component of the initial gas mixtures and the method of determining the composition of the C_4 fraction were described in the preceding paper [3]. All of the catalysts were samples from the same preparation.

EXPERIMENTAL

Table 1 gives details of experiments on the hydrocondensation of carbon monoxide with 2-butene at 190° and atmospheric pressure in a continuous-flow system. The glass reaction tube was 12 mm in diameter. Catalysts 68-72 were used (30 ml of each, except Catalyst 71, of which 50 ml was taken), and these were regenerated after every 15 hours. The ingoing mixture was prepared from 2-butene that contained no 1-butene or isobutene as impurity and had a vapor pressure at 0° (P_0) of 728-732 mm, which corresponds to trans-2-butene in admixture with 2.2-7.6% of cis-2-butene. The mixture consisted of 70-75% of 2-butene, 21-26% of hydrogen, and 4-6% of carbon monoxide.

The gas was passed over the catalyst at a space velocity of 100 $hour^{-1}$. As can be seen from Table 1, the yield of liquid hydrocarbons calculated on $C_4H_8 + H_2 + CO$ was 350-550 ml per cu.m or 32-55 ml per liter of catalyst per hour, the contraction in the gas being 33-39.5%. The ratio of heavy oil to light was 1.2 : 3.2.

TABLE 1

Catalyst	Experiment	Duration of expt. (hour)	Space velocity (hour^{-1})	Contraction	Composition original gas (% by vol)			Yield (ml/cu.m)			Yield of H + L (ml/liter.hour)
					2-Butene	H_2	CO	Heavy oil (H)	Light oil (L)	H + L

TABLE 2

Fraction	B.p. (°C)	Content of fraction in outgoing gas	Composition of fraction		
			Gas	(% on fraction)	(% on outgoing gas)
I	−160 to −110	26.0	H_2	63.0	16.4
			CO	14.6	3.8
			CH_4	22.4	5.8
II	−110 to −10	4.5	C_2H_4	2.8	0.13
			C_2H_6	17.8	0.8
			$C_3H_6+C_3H_8$	74.0	3.33
			CO	5.4	0.24
III	−10 to 2	69.5	2-Butene	95.5	66.4
			Butane	4.5	3.14

In some experiments the composition of the outgoing gas was determined, and on the basis of the results obtained the extent to which each component of the original mixture took part in the reaction was determined. As an example we will cite the results obtained in Experiment 294 (Table 1). In this experiment we passed 19600 ml of gas (STP) of the composition shown in Table 1 and, apart from liquid condensate, we obtained 11600 ml of gas, of which 2700 ml did not condense and 8900 ml did condense at −70°. Part (3000 ml) of the gas obtained was fractionated through a Podbielniak low-temperature column. The results of the fractionation are shown in Table 1 and Fig. 1.

Fraction III had P_0 732 mm and contained neither 1-butene nor isobutene. The original 2-butene had P_0 731 mm, corresponding to trans-2-butene in admixture with 3.4% of cis-2-butene. Fraction III contained 4.8% of cis-2-butene. Analysis of the results given in Table 2 showed that 2-butene reacted to the extent of 47.2%, hydrogen to the extent of 54.3%, and carbon monoxide to the extent of 45.8%. The products of hydrocracking ($C_1 + C_2 + C_3$) corresponded to about 2% of the original 2-butene and about 4% of the 2-butene that reacted; the corresponding figures for butane were 2.5% and 5.0% approximately.

The liquid condensate (about 170 ml) obtained in Experiments 293-301 was separated from water formed in the reaction, washed twice with 2% caustic soda, washed with water until neutral, and sealed in a tube over anhydrous copper sulfate. After being dehydrated, the condensate was filtered from copper sulfate and "debutanized" in a low-temperature column, about 18% by volume of the condensate being distilled off below 20°; the

Original condensate	—	—	1.4179	0.7382	—

distillate contained 85.8% of 2-butene and 14.2% of butane. These amounts of 2-butene and butane, which must be taken into account in the investigation of the outgoing gas, are so small that they do not introduce any substantial changes in the composition as calculated above. After being debutanized the condensate had n_D^{20} 1.4215 and d_4^{20} 0.7389; the refractive index did not change when the condensate was boiled over sodium for two hours under a short low-temperature column.

The debutanized condensate (90 ml; bromine value 38.9, corresponding to about 37% of unsaturated hydrocarbons) was hydrogenated in presence of platinized charcoal (3 ml) to which H_2PtCl_6 had been added [4].

After the absorption of 3500 ml (STP) of hydrogen, a further 1 ml of platinized charcoal was added and a further 100 ml of hydrogen was then absorbed. After being dried over copper sulfate the hydrogenation product had n_D^{20} 1.4178, d_4^{20} 0.7362, and bromine value 0.6. The product (73 ml) was fractionated at 747 mm through a 40-plate column.

About 26% by volume came over below 130°. The fractionation curve is shown in Fig. 2. The residue from the distillation through the column was distilled from a Favorsky flask. All of the fractions collected and their properties are given in Table 3. The intermediate fractions, which amounted to less than 0.3% are not given in Table 3.

It follows from Table 3 and Fig. 2 that about 30% by volume of the condensate comes over below 153°, and this contains C_5, C_6, C_7, C_8, and C_9 hydrocarbons in the proportions of about 1 : 6 : 9 : 8 : 4. The pentane fraction (Fraction I, b.p. 36-38°, n_D^{20} 1.3579), which formed 0.8% of the condensate, consisted of n-pentane (the literature [5] gives b.p. 36.07°, n_D^{20} 1.3575). Fraction III corresponded most closely in properties to 2-methylpentane (b.p. 60.27°, n_D^{20} 1.3715, d_4^{20} 0.6532 [5]), and Fraction IV, b.p. 68-69°, n_D^{20} 1.3750, d_4^{20} 0.6580, was n-hexane (the literature [5] gives b.p. 68.74°, n_D^{20} 1.3749, d_4^{20} 0.6594. The heptane fraction (Fraction VI) had the constants n_D^{20} 1.3859, d_4^{20} 0.6806, which are somewhat low in comparison with those of n-heptane (b.p. 98.43°, n_D^{20} 1.3877, d_4^{20} 0.6837 [5]).

Of the heptane isomers having one side chain only 2-methylhexane has lower constants (b.p. 90.05°, n_D^{20} 1.3849, d_4^{20} 0.6786 [5]) than n-heptane, and we may therefore assume that Fraction VI contains some of this hydrocarbon. Fraction VIII, b.p. 110-127°, n_D^{20} 1.3967, d_4^{20} 0.7013, is close in properties to n-octane (b.p. 125.67°, n_D^{20} 1.3974, d_4^{20} 0.7025 [5]), but its constants are somewhat low. In this case only 2-methylheptane (b.p. 117.65°, n_D^{20} 1.3950, d_4^{20} 0.6979 [5]) has lower constants than n-octane, and it may be assumed that it is present in Fraction VIII. This is confirmed also by the presence on the fractionation curve (Fig. 2) of a step corresponding to n-octane. We are not here taking account of more highly branched hydrocarbons because their formation is not very likely under the conditions of reaction.

When Fractions VIII and VI and a mixture of Fractions III and IV were investigated by the Raman-spectrum method*, only C_5, C_7, and C_8 n-alkanes were detected, the corresponding characteristic wave numbers (cm^{-1}) being: Fraction VIII - 813, 860, 878, 895, 1030, 1044, 1062, 1085, 1140, 1304, 1440, 1460; Fraction VI - 310, 836, 852, 905, 1080, 1140, 1305, 1440, 1460; mixture of Fractions III and IV - 826, 893, 901, 1040, 1140 [1].

It will be clear from these results that the hydrocondensate obtained from carbon monoxide and 2-butene consists essentially of normal alkanes, probably together with a small amount of 2-methylalkanes. The results show that 2-butene itself participates only to an insignificant extent in the hydrocondensation reaction, the reaction products being mainly formed from a 1-alkene, i.e. from 1-butene, which is doubtless formed by the catalytic isomerization of 2-butene.

In the preceding paper [3] we studied the catalytic isomerization of 2-butene into 1-butene and of 1-butene into 2-butene under the conditions of the hydrocondensation of carbon monoxide with olefins, both in presence and in absence of hydrogen, but always in absence of carbon monoxide. It was shown that the hydrocondensation catalyst is active in the reaction of double-bond displacement only when hydrogen is present. 1-butene in admixture with 10% of hydrogen being partially isomerized into 2-butene with formation of an approximately equimolecular mixture of 1-butene and 2-butene. On the other hand, in experiments with 2-butene passed in admixture with 10 or 26% of hydrogen over the hydrocondensation catalyst under the same conditions, no 1-butene was found in the outgoing gas, in spite of the fact that there should be about 10% present in an equilibrium mixture. In the isomerization experiments, both on 1-butene and on 2-butene, a considerable proportion of the olefin remained adsorbed on the catalyst surface and some of it was hydrogenated to butane (somewhat more in the 1-butene experiments than in those on 2-butene).

The results obtained in the present investigation show quite clearly that, under hydrocondensation conditions, isomerization of 2-butene into 1-butene does occur, but the 1-butene formed (calculation shows that not more than 5-6% can be formed) remains adsorbed on the catalyst surface and then, when it becomes possible to

* The spectra were determined by Yu. P. Egorov, to whom we express our thanks.

enter into the reaction of hydrocondensation with carbon monoxide, is converted into high-boiling products; the 2-butene continues to isomerize into 1-butene.

Hence, the products of the hydrocondensation of 2-butene with carbon monoxide are really formed from the 1-butene produced by displacement of the double bond of 2-butene. It is interesting that the whole of the 1-butene formed in this way takes part in the hydrocondensation reaction, for, as we saw above, only 2-butene is present in the outgoing gas.

The formation of some of the products of the hydrocondensation of carbon monoxide with 2-butene can be expressed schematically as follows.

1) Isomerization of 2-butene into 1-butene [8]:

2) Formation of pentene:

In a previous investigation [7] 5.5-7% of a C_6 fraction was obtained in the hydrocondensation of 1-hexene with carbon monoxide, and this could be formed only by the hydrocracking of the original 1-hexene and its transformation products. In experiments with 2-butene in the present investigation, hydrocracking products (about 4%) boiling lower than the butenes were again obtained. It is probable that olefins containing five or more carbon atoms can also be formed to some extent by the hydrocracking of hydrocarbons of higher molecular weight formed in the reaction.

3) The formation of 2-methylpentane, 2-methylhexane, and 2-methylheptane, which appear to be formed in small amounts, can be represented as follows, the starting substance being 1-butene [8]:

Hydrogenation of the adsorbed isomeric methylpentenes give 2-methylpentane. 2-Methylhexane and 2-methylheptane can be formed from methylpentene by analogous reactions, and these may arise also by the polymerization and copolymerization of olefins formed by hydrocracking.

4) Formation of octene by dimerization [8]:

CHEMICAL CHANGES PRODUCED IN THE CELLULOSE MACROMOLECULE BY OXIDIZING AGENTS

COMMUNICATION 10. OXIDATION OF HYDROXY COMPOUNDS OF LOW MOLECULAR WEIGHT WITH NITROGEN DIOXIDE

E. D. Kaverzneva, V. I. Ivanov, and A. S. Salova

In the literature the view is widely held that, in the cold, nitrogen dioxide is a specific oxidant for carbohydrates, in which it attacks primary alcohol groups, but has no effect on secondary alcohol groups. On the basis of this hypothesis, nitrogen dioxide has been used for the preparation of glucosiduronic acids from glucosides [1] in 75-80% yield and dicarboxylic acids from monosaccharides in 44% yield [2]. On the basis of the same hypothesis, Kenyon has stated that cellulose oxidzed with nitrogen dioxide is a "celluronic acid", i.e., that the C-6 primary alcohol groups of the glucose residues are oxidized to carboxyl groups and no other oxidative changes occur [3].

Doubt has been thrown on the correctness of this assertion by us, by Nevell [4], and by Nabar and Padmanabhan [5]. According to our work [6], in the preparation of oxycelluloses by NO_2 oxidation, not only are the primary alcohol groups oxidized, but also the secondary alcohol groups, which are converted into keto groups. It was therefore of interest to obtain a more precise idea of the course of the oxidative reactions occurring when nitrogen dioxide reacts with various hydroxy compounds of low molecular weight. For this purpose we selected isopropyl alcohol, ethylene glycol, 1,2-propanediol, and methyl glucoside.

EXPERIMENTAL

The hydroxy compounds were oxidized with nitrogen dioxide in carbon tetrachloride solution at not above 20°, the medium either being anhydrous or having an addition of 5% of water on the weight of hydroxy compound so that the effect of water on the course of the reaction could be determined. The amount of nitrogen dioxide (distilled over phosphoric oxide and oxidized to completion in a current of oxygen; b.p. 21.2-21.5°) brought into reaction was 50% of the amount calculated for the complete oxidation of all primary alcohol groups to carboxyls and all secondary alcohol groups to keto groups. The hydroxy compounds were dried and distilled before reaction. Isopropyl alcohol boiled at 82.1° and contained 0.1% of acetone; ethylene glycol had b.p. 195°, n_D^{20} 1.4319; 1,2-propanediol had b.p. 104° (30 mm), n_D^{20} 1.4330; methyl glucoside melted at 166°.

The reaction was carried out in a three-necked flask fitted with condenser, stirrer, and dropping funnel. A weighed amount (0.2-0.5 mole) of the hydroxy compound, contained in 50 ml of carbon tetrachloride, was introduced into the flask, and a solution of the required amount of nitrogen dioxide in 50 ml of carbon tetrachloride was added through the dropping funnel. Heat was evolved, and the mixture was cooled so that the temperature did not rise above 20°. The reaction mixture was stirred for 1-2 hours, and then set aside at room temperature for 20 hours. Oily drops generally floated on the top of the greenish-yellow solution. After 20-24 hours the reaction was brought to an end, the excess of nitrogen oxides being removed in the cold under reduced pressure. The solution was poured into water, the liquid layers were separated, and the carbon tetrachloride layer was washed several times with water. The aqueous and carbon tetrachloride layers were investigated separately.

TABLE 1
Summary of Oxidation Experiments

Experiment No.	Composition of reaction mixture (moles)	Experimental conditions	Water-soluble fraction		Total yield from aqueous fraction and hydrolyzed CCl_4 fraction (%)
			Carbonyl compounds (mg-equiv)	Acids (mg-equiv)	
1	Isopropyl alcohol 0.52, NO_2 0.26	26°, 25 hours	Acetone 11.5	Formic acid 0.2, acetic acid	Acetone 4.7
2	Isopropyl alcohol 0.52, NO_2 0.26, H_2O 0.08	26°, 25 hours	Acetone 29.6	Formic acid 0.16, acetic acid	Acetone 12
3	Ethylene glycol 0.25, NO_2 0.50	14°, 24 hours	Glycolaldehyde traces	Glycolic acid present, oxalic acid traces	–
4	Ethylene glycol 0.25, NO_2 0.50, H_2O 0.05	14°, 24 hours	Glycolaldehyde traces	Glycolic acid present, oxalic acid 3.1	Oxalic acid 1.26
5	1,2-Propanediol 0.40, NO_2 0.60	20°, 24 hours	Hydroxyacetone 0.01	Pyruvic acid present	Hydroxyacetone 0.0025
6	1,2-Propanediol 0.40, NO_2 0.60, H_2O 0.17	20°, 24 hours	Hydroxyacetone 0.04	Pyruvic acid present	Hydroxyacetone 0.01
7	Methyl glucoside 0.127, NO_2 0.39	20°, 24 hours	Hydroxy keto compound 1.24	Methyl glucosiduronic acid 10.0	Glucosiduronic acid 8.0*, keto compound derived from glucosiduronic acid 0.97
8	Methyl glucoside 0.09, NO_2 0.33, H_2O 0.04	20°, 24 hours	Hydroxy keto compound 2.6	Methyl glucosiduronic acid 6.93	Glucosiduronic acid 7.0**, keto compound derived from glucosiduronic acid 10.8

* 2.34 g of barium salt was isolated.
** 1.52 g of calcium salt was isolated.

Investigation of Water-soluble Fraction. The total acidity was determined, and part of the neutralized aqueous solution was vacuum-distilled, the volatile aldehydes being trapped in sodium bisulfite solution. The residue was then acidified, and the volatile acids were trapped in 0.5 N NaOH. Aldehydes and volatile acids (formic, acetic, nitrous, and nitric) were determined in the respective distillates. The same determinations were carried out with part of the solution in which nitrite ions had been destroyed by addition of urea. The residue from the distillation contained compounds of low volatility, which were identified by the preparation of derivatives, by quantitative methods of estimation, and, in some cases, by paper chromatography. The results of the investigation of the composition of the oxidation products are given in Table 1.

Investigation of Reaction Products Soluble in Carbon Tetrachloride. After being carefully washed with water and dried over sodium sulfate, solutions of the reaction products in carbon tetrachloride were yellowish. Nitrite ions were formed when the solutions were treated with alkali. The solutions were investigated for the presence of nitric and nitrous esters before and after hydrolytic treatment with alkali at room temperature. In the analysis, 5-ml portions of the carbon tetrachloride solution were measured into two 100-ml measuring flasks, and 20 ml of water was added to each portion.

Into one of the flasks, 1 ml of 40% NaOH was added in order to hydrolyze the esters. The solutions were allowed to stand for 24 hours at room temperature and then brought to 100 ml with water. Nitric acid was determined in this solution colorimetrically with "disulfophenolic" acid [7], and nitrous acid was determined colorimetrically by the 1-naphthol reaction [8]. In some cases, the contents of keto groups and of individual ketones were also determined (Table 2).

TABLE 2
Investigation of Fractions dissolved in Carbon Tetrachloride

Experiment No.	Substance oxidized	Amount of HNO_3 (mg-equiv)		Amount of HNO_2 (mg-equiv)		Found (mg-equiv)	
		Before hydrolysis	After hydrolysis	Before hydrolysis	After hydrolysis	Before hydrolysis	After hydrolysis
						Acetone	
1	Isopropyl alcohol	16.9	1.9	Traces	Several times as great	10.1	13.2
2	Isopropyl alcohol in presence of moisture	13.3	2.8	Traces	Ditto	25	32.7
						Glycoaldehyde	
3	Ethylene glycol	10.8	12.1	Nil	0.20	Nil	Present
4	Ethylene glycol in presence of moisture	3.5	1.9	2.8	8.7	"	"
						Hydroxyacetone	
5	1,2-Propanediol	Nil	0.15	Nil	0.23	Nil	Present
6	1,2-Propanediol in presence of moisture	0.5	2.3	0.19	1.9	"	"
7	Methyl glucoside	Nil	Nil	Nil	Nil	*	—
8	Methyl glucoside in present of moisture	"	"	"	"	—	—

* In the oxidation of methyl glucoside the nitric esters were in the water-soluble fraction. Before hydrolysis the NO_2 content was nil, and after hydrolysis it was 16 mg-equiv.

Oxidation of Isopropyl Alcohol. After the oxidation of isopropyl alcohol, acetone was determined in the distillate of the aqueous layer by the salicylaldehyde colorimetric method (Fabrinf's reaction [9]). This reaction is specific for ketones containing the grouping $-CH_2-CO-CH_2-$, and acetaldehyde and alcohols do not interfere.

The yield of acetone corresponded to 4.7% of the isopropyl alcohol taken when water was absent, and to 12% when water was present. The formation of acetone was confirmed by the preparation of its 2,4-dinitrophenylhydrazone, of which 70 mg were obtained, m.p. 125.5° (the literature gives 126°).

	Found %: N 23.41 (Dumas)
$C_9H_{10}O_4N_4$	Calculated %: N 23.68

Qualitative reactions showed the presence of formic and acetic acids in the volatile-acid distillate. Quantitative determination of formic acid with mercuric chloride gave 0.3 mg-equiv (0.0006%) for oxidation in an anhydrous medium and 0.16 mg-equiv (0.0003%) for oxidation in presence of water.

In the analysis of the fraction soluble in carbon tetrachloride, it was found that it gave a positive reaction for nitrite with the Griess reagent, and the color was more intense when a preliminary treatment with alkali was given. When the solution was made alkaline and allowed to stand, it became acid again owing to the hydrolysis of nitric or nitrous esters. It was established that, after alkaline hydrolysis, the nitric acid content (free and bound as ester) fell and nitrous acid appeared, although this was usually present only in traces before hydrolysis.

Nitrous acid could be formed by hydrolysis of isopropyl nitrite with regeneration of isopropyl alcohol, and also by oxidative hydrolysis of isopropyl nitrate. In the latter case acetone would be formed. Colorimetric determinations showed that, in the experiment under anhydrous conditions, 13.2 mg-equiv of acetone was formed after hydrolysis of the fraction soluble in carbon tetrachloride, and in the experiment in presence of water 32.7 mg-equiv of acetone was formed. There was therefore an appreciable amount of isopropyl nitrate in the carbon tetrachloride solution, and on hydrolysis this was converted into acetone with formation of nitrous acid.

$$CH_3-\underset{\underset{ONO_2}{|}}{CH}-CH_3 \xrightarrow{OH^-} CH_3COCH_3 + NO_2' + H_2O.$$

Oxidation of Ethylene Glycol. The aqueous fraction from the oxidation of ethylene glycol did not give aldehyde reactions and therefore did not contain glycolaldehyde. After removal of volatile acids under reduced pressure, oxalic acid was precipitated as the calcium salt in presence of ammonia and ammonium chloride. The precipitate was washed through with dilute hydrochloric acid, and oxalic acid was determined by titration with 0.1 N $KMnO_4$.

Fig. 1. Chromatograms: A) experimental solution; B) glycolic acid

In the oxidation in an anhydrous medium, the aqueous fraction contained only traces of oxalic acid, whereas in the experiment in presence of water, 0.140 mg of oxalic acid was found (1.15% on the amount of ethylene glycol taken). Apart from oxalic acid, glycolic acid was detected by paper chromatography (solvent: a 10 : 2 : 8 mixture of butyl alcohol, formic acid, and water; developer: Bromophenol blue) (Fig. 1).

When the fraction soluble in carbon tetrachloride was hydrolyzed with 2% caustic soda in the cold, nitrous acid was formed and the solution gave a positive result with Schiff's reagent. In an acid medium no hydrolysis occurred and no nitrous acid was formed.

Oxidation of 1,2-Propanediol. The aqueous fraction from the oxidation of 1,2-propanediol gave no reaction with Schiff's reagent. The reaction with Fehling's solution was positive in the cold, as also was Benedict's reaction for the hydroxy ketone grouping. Practically no volatile acids were formed. The residue remaining after the removal of volatile compounds was heated with an alcoholic solution of 2,4-dinitrophenyl-

hydrazine and hydrogen chloride, and an osazone, m.p. 290.5-300° (after recrystallization from ethyl acetate), was isolated. For the osazone of hydroxyacetone the literature gives m.p. 300°. In Experiment 5 the amount of osazone isolated corresponded to 0.67 mg of hydroxyacetone, and in Experiment 6 it corresponded to 2.72 mg.

Hydrazones of keto acids were extracted by means of sodium carbonate solution from the mother liquor left after the crystallization of the osazone of hydroxyacetone. After acidification and extraction of the solution with ethyl acetate, a small amount of hydrazones was obtained. In order to test for the presence of the 2,4-dinitrophenylhydrazone of pyruvic acid, the material was investigated chromatographically against a synthetic preparation (m.p. 218°) obtained by the condensation of pyruvic acid with 2,4-dinitrophenylhydrazine. In the separation on paper (solvent: butyl alcohol saturated with 3% ammonia solution), two pairs of spots were obtained; these corresponded exactly with one another and with data in the literature [10], according to which this hydrazone, like free pyruvic acid, gives two spots in paper chromatography (Fig. 2).

Fig. 2. Chromatograms: A) experimental solution; B) pyruvic acid

Fig. 3. Chromatograms: A) lactic acid; B) nitric acid; C) experimental solution; D) pyruvic acid

Direct chromatographic separation of the aqueous fraction of acids on paper showed the presence of pyruvic and nitric acids in the oxidation products of 1,2-propanediol; no lactic acid was detected (Fig. 3). In the fraction that dissolved in carbon tetrachloride, an appreciable amount of nitrous acid was formed after hydrolysis with 2% caustic soda in the cold. Before hydrolysis the colorimetric reaction with salicylaldehyde for hydroxyacetone was negative, but after hydrolysis it was positive, thus indicating the formation of hydroxyacetone in the hydrolysis.

Oxidation of Methyl α-Glucoside. In the oxidation, 2.5 moles of nitrogen dioxide were taken for each mole of the glucoside. As oxidation proceeded the appearance of the suspension of methyl glucoside in carbon tetrachloride changed and it gradually became a sticky greenish sirup. This was allowed to stand for 24 hours, nitrogen oxides were removed in the cold under reduced pressure, and the product was treated with water, yielding an aqueous layer, which contained the bulk of the reaction products, and a carbon tetrachloride layer, which did not contain an appreciable amount of oxidized compounds.

There were no aldehydes and voltaile organic acids in the aqueous layer. After the content of nitric and nitrous acids had been taken into account, the acidity of the aqueous layer was still high, which indicated that much of the glucoside had been oxidized. The aqueous layer gave an intense reaction with Benedict's reagent for α-hydroxy ketone groupings [11], the amount of which was found to be 1.24 mg-equiv (0.97% of the amount calculated for the oxidation of one alcohol group) for reaction in an anhydrous medium and 9.6 mg-equiv (10.8%) for reaction in presence of water. When allowed to stand in an alkaline medium, the aqueous fraction became acid, the extent of the acidification being 12% of the acidity of the original solution. As acidity developed there was an increase in the content of nitrite ions.

Methyl glucosiduronic acid was isolated in Experiment 7 as the barium salt (1.74 g from one half of the volume of the reaction products) and in Experiment 8

as the calcium salt (1.52 g). The salts were not purified from inorganic salts, but were used directly for the preparation of osazones in order to prove the presence of keto derivatives. According to the analysis of the barium salt, it contained hydroxy ketone groupings in an amount corresponding to 2.7% admixture of an oxidized methyl glucosiduronic acid containing a keto group to the main mass of methyl glucosiduronic acid.

When the barium and calcium salts were treated with a solution of 2,4-dinitrophenylhydrazine in aqueous 2 N HCl at 5-7°, osazones of high melting point (above 340°) were obtained; they gave a bluish-violet color with alkalis, and they were soluble in ethyl acetate.

Found %: N 19.74 (osazone from Ba salt)
Found %: N 19.57; 19.93 (osazone from Ca salt)
$C_{25}H_{28}O_{13}N_8$. Calculated %: N 19.86

The corresponding osazone of glucuronic acid, which could be formed if the glucoside methyl were to be eliminated, contains 20.30% N, i.e. appreciably more than the amount found.

A more complete analysis of the osazones obtained could not be carried out owing to their small amount. All of these facts lend a considerable measure of probability to the suggestion that the glucosiduronic acid was admixed with some oxidized glucosiduronic acid containing a keto group formed by the oxidation of a secondary alcohol group of methyl glucoside.

Discussion of Experimental Results

Oxidation of hydroxy compounds with nitrogen dioxide under the given experimental conditions - in the cold for a comparatively short time (24 hours) with half of the amount of nitrogen dioxide that would be theoretically required for complete oxidation - does not result in far-reaching decomposition. On this account, examination of the reaction products enables us to determine the primary direction in which the oxidation processes proceed.

The formation of appreciable amounts of acetone (up to 12%) from isopropyl alcohol and of hydroxyacetone from 1,2-propanediol, and also the formation of hydroxy ketone groupings in the oxidation of methyl glucoside, shows that secondary alcohol groups are oxidized by nitrogen dioxide under the given conditions. Moreover, oxidation does not stop at this stage, but continues further with scission of a C–C bond, as indicated by the presence of small amounts of formic and acetic acids in the reaction products.

In the oxidation of ethylene glycol the successive stages in the oxidation of the two alcohol groups can be observed, glycolic and oxalic acids being formed. In the oxidation of 1,2-propanediol, the number of possible oxidation products increases:

From the reaction products an osazone was isolated which corresponds in analysis to:

This osazone could be formed from any of the three carbonyl compounds given in the scheme. However, as the solution does not give a reaction for aldehyde groups while giving a strongly marked reaction for hydroxy ketone groupings, the question is resolved in favor of hydroxyacetone as one of the primary products of the oxidation of 1,2-propanediol with nitrogen dioxide. Direct colorimetric determination of hydroxyacetone in the reaction products gave a content corresponding to 0.002-0.01% of the theoretically possible content for the oxidation of one hydroxy group per molecule. Since 1,2-propanediol has a glycol grouping in which one hydroxyl is primary and the other secondary, it was of interest to determine which of the two alcohol groups is preferentially oxidized. One might expect that lactic acid would be the main reaction product, and pyruvic acid would be a secondary product. However, the presence among the reaction products of hydroxyacetone and pyruvic acid and the absence of detectable amounts of lactic acid indicate that the oxidation processes proceed in a different way, the predominating process being the oxidation of the secondary alcohol group. A different picture is to be observed in the oxidation of methyl glucoside: here, the main direction of reaction in an anhydrous medium is the oxidation of the primary alcohol group at the terminal carbon atom (to the extent of 8%). The oxidation of secondary alcohol groups occurs only to a slight extent (not more than 1%), as our experiments have shown, and only in the presence of water - when far-reaching decomposition sets in - are hydroxy ketone groupings formed to an appreciably greater extent (10-11%).

The effect of molecular structure is to be seen in this difference in order of oxidation: when there is a methyl group in proximity to a hydroxyl, the secondary alcohol group is more readily oxidized, but in carbohydrates, in which all carbons carry OH groups, the primary alcohol group is oxidized first:

Hence, 1,2-propanediol gives hydroxyacetone as main product, whereas methyl glucoside gives methyl glucosiduronic acid.

As we have shown, in the fraction of the oxidation products that passes into carbon tetrachloride (or into water, in the case of methyl glucoside), there are compounds that eliminate nitrous acid when treated with alkali in the cold. These could be nitrous or nitric esters of oxidizable alcohols. As it is found that hydrolysis is accompanied by the formation of ketones or aldehydes (acetone from isopropyl alcohol, hydroxyacetone from 1,2-propanediol, and an aldehyde from ethylene glycol), it is probable that oxidative hydrolysis of nitric esters occurs, in accordance with the scheme:

Hence, the mechanism proposed by Kenyon [12], in which the oxidation of cellulose proceeds with intermediate formation of nitric esters, can probably be extended to the oxidation of hydroxy compounds of low molecular weight with nitrogen dioxide. The general character of this reaction follows also from Titov's investigations [13], which show that, in the nitration of hydrocarbons, in addition to nitro derivatives nitric and nitrous esters of the corresponding alcohols are formed and are subsequently oxidized. In our experiments, the effect of water was very marked; in presence of moisture oxidation always proceeded more vigorously and the yields of oxidation products were higher than in a dry anhydrous solvent. This fact can also be interpreted in the light of the proposed oxidation mechanism, in accordance with which the primary stage of the reaction is the formation of a nitric ester by the action of nitric acid formed from nitrogen dioxide and traces of moisture.

SUMMARY

1. The main product in the oxidation of isopropyl alcohol by nitrogen dioxide at room temperature is acetone. In different experiments the yield of acetone varies from 2% to 12% on the amount of alcohol taken.

2. The oxidation of ethylene glycol with nitrogen dioxide proceeds in such a way that it is difficult to characterize the intermediate products in the oxidation. The process rapidly reaches the stage of oxalic acid formation. Oxalic and glycollic acids were identified.

3. Among the oxidation products of 1,2-propanediol, hydroxyacetone and pyruvic acid were identified. No lactic acid was found. This indicates that the predominating process is the oxidation of secondary alcohol groups.

4. A study of the oxidation of methyl α-glucoside with nitrogen dioxide under the same conditions showed that not only primary, but also secondary alcohol groups are oxidized. In the methyl glucosiduronic acid obtained from the products as the barium and calcium salts, another compound, containing a hydroxy ketone grouping, was present as impurity. An osazone was prepared from this compound, and it corresponded in analysis to the osazone of an oxidized methyl glucosiduronic acid containing a keto group.

5. It was established that the process of oxidizing alcohols of low molecular weight and methyl glucoside with nitrogen dioxide proceeds through the stage of a nitric ester, which undergoes oxidative hydrolysis with elimination of nitrous acid.

NEW DATA ON THE HOFMANN REACTION

COMMUNICATION 4. ACTION OF HYPOBROMITE ON DIASTEREOISOMERIC 3-(ACYLAMINO)-4-ETHYLOCTANAMIDES

V. M. Rodionov*, V. K. Zvorykina, and N. E. Kozhevnikova

In previous investigations on the Hofmann reaction of amides of β-acylamino acids, namely derivatives of 3-aminononanoic [1], β-aminohydrocinnamic [2], and β-amino-3,4-methylenedioxyhydrocinnamic [3] acids, it was shown that acids containing aromatic and aliphatic radicals behave differently. Although in the first stage of the reaction the same type of product is formed in both cases by intramolecular rearrangement of the isocyanate - the corresponding 1-acyl-5-alkyl(or aryl)-2-imidazolidinone - the second stage - hydrolysis of the acyl group and formation of a 5-alkyl (or aryl)-2-imidazolidinone - proceeds considerably more rapidly in the case of an amino acid containing an aromatic radical. The further transformation of the imidazolidinone, leading finally to a carboxylic acid, proceeds, in the case of a β-amino acid containing an aliphatic radical, through the stages of the formation of an alkylhydantoin, an α-ureido acid, and an α-amino acid, but in the case of a β-amino acid containing an aromatic radical through the intermediate formation of an aroylurea and a 5-aryl-Δ^4-1,3,4-oxadiazolin-2-one.

With the object of confirming previous observations, we carried out Hofmann's reaction with amides of benzoyl and alkoxycarbonyl derivatives of two diastereoisomeric 3-amino-4-ethyloctanoic acids which we have synthesized and denoted by the symbols A_1 and A_2 [4]. Reaction with the benzoyl derivative stopped at the stage of the imidazolidinone. As by-products, both isomers gave high-melting neutral substances corresponding in analysis to alkylarylureas. Reaction of the isocyanate in this direction is generally observed when the amides are sparingly soluble, and we have observed it also in a previous investigation [5]. When the Hofmann reaction was carried out with amides of alkoxycarbonyl derivatives of the isomers A_1 and A_2, products obtained were the 1-alkoxycarbonyl-5-(1-ethylpentyl)-2-imidazolidinone, 4-(1-ethylpentyl)-2-imidazolidinone, 5-(1-ethylpentyl)-hydantoin, and 2-ethylhexanoic acid. Also, when the oil remaining after the separation of these compounds was hydrolyzed, the presence of 2-ethylhexanal, ammonia, and hydrogen cyanide was detected in the product. From

* Deceased.

this it may be inferred that, as in the case of other aliphatic β-amino acids, for the new representatives of this class of compound that we have studied, the process proceeds in accordance with the general scheme that we proposed in a previous paper [1].

EXPERIMENTAL

Hofmann Reaction with 3-Benzamido-4-ethyloctanamide (A_2 Isomer)

The amide (4 g) was gradually added to a hypobromite solution prepared from 1.75 g of bromine, 6.45 g of caustic potash, and 45 ml of water at −7 to −10°*. When solution was complete, stirring was continued for one hour. The solution was then heated to 65° and cooled rapidly. The solution and the precipitate that had formed were treated with ether.

Isolation of Benzoic Acid. Acidification of the alkaline solution yielded 0.35 g of benzoic acid, m.p. 122°.

Isolation of Substance of M.p. 219°. The ether-insoluble precipitate was boiled with water and crystallized from alcohol. The product, amounting to 0.4 g, melted at 219° (fine colorless prisms).

		Found %	C	71.02; 70.93;	H	8.74; 8.67;	N	9.30; 9.45
$C_{24}H_{30}O_4N_4$.	Calculated %	C	70.59;	H	8.65;	N	9.67	

Isolation of 1-Benzoyl-5-(1-ethylpentyl)-2-imidazolidinone A_2. The ether solution was extracted several times with 12% hydrochloric acid, washed, first with water, then with caustic soda solution, and again with water, and dried with sodium sulfate. After part of the ether had been distilled off, 1.2 g of a substance of m.p. 153°, was obtained.

		Found %	C	70.98; 70.79;	H	8.59; 8.36;	N	9.70; 9.69
$C_{18}H_{26}O_2N_2$.	Calculated %	C	70.83;	H	48.33;	N	9.72	

Further removal of ether enabled about 0.5 g more of the imidazolidinone A_2 to be isolated. When ether was removed completely there remained an oil, and treatment of this with a mixture of diethyl ether and petroleum ether gave 0.04 g of a substance melting at 143° which did not appear to be the imidazolidinone A_2 isolated as indicated above.

Found %	N	11.48;	11.51	

This substance was not studied in detail.

Isolation of 4-(1-Ethylpentyl)-2-imidazolidinone A_2. Cooling of the hydrochloric acid solution and careful addition of solid caustic potash yielded 0.29 g of a substance of m.p. 140-141° (needles from a mixture of diethyl ether and petroleum ether).

		Found %	C	65.31;	H	10.50;	N	15.47; 15.39
$C_9H_{18}ON_2$.	Calculated %	C	65.21;	H	10.86;	N	15.21	

Hydrolysis of 1-Benzoyl-5-(1-ethylpentyl)-2-imidazolidinone A_2. Heating of 0.3 g of the benzoylimidazolidinone A_2 with 20% caustic soda for four hours in a water bath yielded 0.06 g of benzoic acid, m.p. 121°, 0.07 g of the above described 4-(1-ethylpentyl)-2-imidazolidinone, m.p. 139-140°, and 0.01 g of the above-described substance of m.p. 148°.

Hofmann Reaction with 3-Benzamido-4-ethyloctanamide (A_1 Isomer)

When the reaction was carried out with 6.81 g of amide under the conditions described for the A_2 isomer, acidification of the alkaline solution yielded 0.21 g of benzoic acid. The ether-insoluble precipitate gave 0.43 g of a substance of m.p. 204°.

* Experimental investigation of the Hofmann reaction applied to 3-benzamido-4-ethyloctanamide A_1 was carried out by N. E. Kozhevnikova. All of the remaining experimental work was carried out by V. K. Zvorykina.

Found %: C 71.83; 72.01; H 8.85; 9.00; N 9.78; 9.69

The ether solution yielded 2.55 g of 1-benzoyl-5-(1-ethylpentyl)-2-imidazolidinone A_2, m.p. 141-142° (needles from ether). A mixture with the A_2 isomer melted at 114-116°.

Found %: C 70.64; 70.52; H 8.38; 8.52; N 9.85; 9.92

The hydrochloric acid solution yielded 0.25 g of 4-(1-ethylpentyl)-2-imidazolidinone A_2, m.p. 141-142° (colorless needles from ether). A mixture with the A_1 imidazolidinone melted at 117-123°.

Found %: C 65.15; 65.29; H 10.92; 10.99; N 15.51; 15.34

Hydrolysis of 1-benzoyl-5-(1-ethylpentyl)-2-imidazolidinone A_1 gave benzoic acid and 4-(1-ethylpentyl)-2-imidazolidinone A_2, m.p. 139-140°.

Hofmann Reaction with 4-Ethyl-3-(methoxycarbonylamino)octanamide (A_1 Isomer)

The amide (20 g) was added in small portions with stirring to a cooled (−3°) solution of hypobromite prepared from 40 g of caustic potash, 280 ml of water, and 10.3 ml of bromine. When solution was complete (about three hours), stirring was continued for one hour at room temperature and the flask was then transferred to a water bath and the temperature raised to 65° (at 55° a spontaneous rise in temperature occurred). The flask was then rapidly immersed in a cooling mixture. The alkaline solution containing precipitated oil was extracted with ether, and the ether extract was extracted several times with 12% hydrochloric acid.

Isolation of 5-(1-Ethylpentyl)hydantoin A_1 and 2-Ethylhexanoic Acid. When the alkaline solution was acidified an oil separated and was extracted with ether; the ether solution was washed with water and dried with sodium sulfate. After removal of ether there remained 1.3 g of oil, which partially crystallized; when this was treated with 10 ml of heptane, crystals were precipitated, which were twice reprecipitated from an alkaline solution with acid and then recrystallized from water. The yield of the hydantoin A_1 was 0.09 g, m.p. 140-141°.

Found %: C 60.66; 60.22; H 9.20; 9.03; N 14.36; 14.25

$C_{10}H_{18}O_2N_2$. Calculated %: C 60.60; H 9.09; N 14.14

When the heptane was distilled off, 0.8 g of liquid 2-ethylhexanoic acid remained; it was characterized as its amide, m.p. 104-105°.

Isolation of 4-(1-Ethylpentyl)-2-imidazolidinone A_1. The hydrochloric acid solution was rendered alkaline with solid potassium hydroxide, cooling being applied. The imidazolidinone obtained (0.75 g) melted at 141-142° (needles from ether) and was identical with that described above.

Isolation of 5-(1-Ethylpentyl)-1-methoxycarbonyl-2-imidazolidinone A_1. After removal of ether, 9 g of oil was obtained, and this crystallized when seeded with 4-(1-ethylpentyl)-2-imidazolidinone. When a little ether was added, 1.2 g of the imidazolidinone A_1 was precipitated. Addition of heptane to the filtrate resulted in the precipitation of a further 0.2 g of the same substance, and after several hours the clear filtrate gave a precipitate of 1.19 g of 5-(1-ethylpentyl)-1-methoxycarbonyl-2-imidazolidinone A_2, m.p. 84.5-85° (from a mixture of diethyl ether and petroleum ether). After the hydrolysis of this compound by boiling it with 20% caustic soda, 4-(1-ethylpentyl)-2-imidazolidinone A_1 was isolated.

Found %: C 59.63; 59.47; H 9.37; 9.45; N 11.79; 11.69

$C_{12}H_{22}O_3N_2$. Calculated %: C 59.50; H 9.09; N 11.57

The oil remaining after the separation of the imidazolidinones was hydrolyzed by heating it with 7.5% caustic soda solution. It was shown that hydrogen cyanide, ammonia, and 2-ethylhexanal (identified as the dinitrophenylhydrazone) were formed.

Hofmann Reaction with 3-(Ethoxycarbonylamino)-4-ethyloctanamide (A_2 Isomer)

The reaction was carried out with 11 g of the amide. The experimental conditions and the methods of isolating the products were similar to those described for the analogous A_1 compound.

Isolation of 5-(1-Ethylpentyl)hydantoin A_2 and 2-Ethylhexanoic Acid. When the alkaline solution was acidified, an oil was precipitated, and when petroleum ether was added to this, 0.078 g of the hydantoin A_2, m.p. 172°, was obtained (purification as for the A_1 isomer).

	Found %:	C 60.49;	60.30;	H 9.37;	9.13;	N 13.90;	14.11
$C_{12}H_{22}O_2N_2$.	Calculated %:	C 60.60;		H 9.09;		N 14.14	

After removal of petroleum ether there remained an oil. Steam distillation of this yielded 0.17 g of 2-ethylhexanoic acid, which was identified as the amide.

Isolation of 4-(1-Ethylpentyl)-2-imidazolidinone A_2. The hydrochloric acid extract yielded 1.33 g of the imidazolidinone A_2, m.p. 140-141°, already described above.

Isolation of 1-Ethoxycarbonyl-5-(1-ethylpentyl)-2-imidazolidinone A_1. After partial removal of ether the solution gave 1.15 g of 1-ethoxycarbonyl-5-(1-ethylpentyl)-2-imidazolidinone A_1, m.p. 88° (colorless plates from ether). Its alkaline hydrolysis gave 4-)1-ethylpentyl)-2-imidazolidinone A_2, m.p. 140°.

After complete removal of ether, 6 g of a noncrystallizing oil was obtained. One half of this was hydrolyzed with 7% caustic soda solution, and the formation of hydrogen cyanide, ammonia, and 2-ethylhexanal was established. In addition, 2.3 g of 4-(1-ethylpentyl)-2-imidazolidinone A_2, m.p. 139-140°, was isolated.

SUMMARY

1. A study was made of the action of hypobromite on the diastereoisomers A_1 and A_2 of 3-benzamido- and 3-(alkoxycarbonylamino)-4-ethyloctanamides.

2. From the products obtained from the benzamido compounds, the stereoisomeric 4-(1-ethypentyl)--2-imidazolidinones and 1-benzoyl-5-(1-ethylpentyl)-2-imidazolidinones, and also benzoic acid, were isolated.

3. From the products obtained from the alkoxycarbonylamino compounds, the stereoisomeric 1-alkoxycarbonyl-5-(1-ethylpentyl)-2-imidazolidinones, 4-(1-ethylpentyl)-2-imidazolidinones, and 5-(1-ethylpentyl)-hydantoins, and also 2-ethylhexanoic acid, were isolated. When the oil remaining after the separation of the above compounds was hydrolyzed, hydrogen cyanide, ammonia, and 2-ethylhexanal were present among the products.

4. The results obtained confirm the correctness of the scheme that we have proposed previously for the Hofmann reaction with amides of acylated β-amino acids.

CHLOROMETHYLATION OF 2,5-DIMETHYLTHIOPHENE

Ya. L. Goldfarb and M. S. Kondakova

Chloromethylation is one of those reactions that are readily affected by various factors. Change of temperature or condensing agent, replacement of formaldehyde by paraformaldehyde, etc., may not only reduce or increase the yield of the product, but may also alter its identity. Lock, in his detailed investigation of the chloromethylation of benzene [1], showed, in particular, the dependence of the yield of benzyl chloride on the zinc chloride content of the reaction mixture and on the duration of the process; the yield of benzyl chloride attains a maximum value (70%) in a certain interval of time and then falls almost to zero as the duration of the experiment increases, this being accompanied by a rapid increase in the yield of diphenylmethane. The peculiar "sensitivity" of this reaction may be the cause of discrepancies in results on chloromethylation obtained by different investigators. As an example we may point out that Lock could not confirm Tschunkur and Eichler's results on the synthesis of benzyl chloride by the chloromethylation method. We came across a similar situation in the chloromethylation of 2,5-dimethylthiophene by the action of formaldehyde and hydrogen chloride in hydrochloric acid under cooling in accordance with the procedure of Buu-Hoi and Nghyen Hoan [2]. According to these investigators, under these conditions a little 3-(chloromethyl)-2,5-dimethylthiophene is formed, but the main product is 3,3'-methylenebis[2,5-dimethylthiophene] (III), m.p. 72°. In our experiments we obtained approximately equal amounts of the mono(chloromethyl) derivative (I) and 3,4-bischloromethyl-2,5-dimethylthiophene (II), but did not succeed in isolating any of the substituted methylenedithiophene (III) of m.p. 72°.

The same two compounds (I) and (II), but in somewhat different proportions, were formed in the chloromethylation of 2,5-dimethylthiophene with chloromethyl methyl ether in glacial acetic acid. In order to confirm the structure of the compound that we regarded as 3-(chloromethyl)-2,5-dimethylthiophene, it was converted via the acetoxymethyl compound into the corresponding alcohol, which, according to its composition and the properties of the urethan derived from it, was identical with 2,5-dimethyl-3-thiophenemethanol (IV), which was prepared by Brown and Blanchette [3] by the reduction of 2,5-dimethyl-3-thiophenecarboxaldehyde. The compound (II), the product of the bischloromethylation of 2,5-dimethylthiophene, was obtained in a yield of about 65% by the chloromethylation of 2,5-dimethylthiophene with paraformaldehyde and hydrogen chloride at 50°, i.e. under conditions almost identical with those described by Gaertner and Tonkyn [4]. It must be pointed out that, in this case also, we failed to detect a product of composition corresponding to the methylenedithiophene of structure (III). We isolated a very small amount of a chlorine-containing product melting at 173° which was identical in properties with the substance obtained by the chloromethylation of a compound that we have isolated in the course of this work (see below); this latter compound melts at 48.5° and corresponds in composition to the compound (III) mentioned above.

We repeatedly prepared the bischloromethyldimethylthiophene (II) by the method indicated, and in all of the experiments it melted, after recrystallization, at 67-68.5°; sublimation did not affect its melting point.

On the other hand, in the paper cited by Gaertner and Tonkyn, a melting point of 73.4° is given for 3,4-bischloromethyl-2,5-dimethylthiophene. This discrepancy might be caused by the constant presence of an impurity, which could arise from the fact that we did not prepare the original dimethylthiophene from 2,5-hexanedione, but by King and Nord's method [5], i.e. the formulation of 2-methylthiophene and subsequent reduction. In its turn, 2-methylthiophene was prepared by the same method from thiophene. It was impossible to be certain that this method gave a pure compound and not a mixture of 2,5- and 2,3-dimethylthiophenes. In order to resolve this doubt we prepared a ketone by the action of acetyl chloride on the synthesized dimethylthiophene and a dinitro derivative by the method of Steinkopf and coworkers [6]. The melting points of the latter and of the oxime of the former corresponded with data in the literature for 2,5-dimethyl-3,4-dinitrothiophene and the oxime of 2,5-dimethyl-3-thienyl methyl ketone, respectively. It was established in this way that the dimethylthiophene that we used was mainly, if not entirely, 2,5-dimethylthiophene.

In order to make sure that the bischloromethyldimethylthiophene of m.p. 68° that we obtained was indeed a tetrasubstituted thiophene having the properties of a bifunctional compound, we investigated some of its reactions. The compound was reduced with stannous chloride [7]; the resulting substance of composition $C_8H_{10}S$ was not acetylated when treated with acetyl chloride in presence of stannic chloride and was identical in physical properties with the tetramethylthiophene described by Gaertner and Tonkyn [4]. When the substance of m.p. 68° was treated with benzene in presence of aluminum chloride, a compound was formed which corresponded in composition with 3,4-dibenzyl-2,5-dimethylthiophene (V)

(V)

which we obtained also by the condensation of 2,5-dimethylthiophene with benzyl alcohol in presence of sulfuric acid [8]. These facts are in accord with the view that the substance of m.p. 68° is indeed a bifunctional derivative.

It was stated above that in chloromethylation experiments on 2,5-dimethylthiophene in the cold and at 50° we did not succeed in isolating a compound corresponding in composition to 3,3'-methylenebis[2,5-dimethylthiophene] (III). It must be pointed out here that Cagniant, who studied the chloromethylation of 2,5-diethylthiophene [9] and 2-ethylthiophene [10] with chloromethyl methyl ether, states that the first of these compounds forms only a little, but the second quite a large amount, of the corresponding substituted methylenedithiophene. Our experiments on the chloromethylation of 2,5-diethylthiophene at 30° with formaldehyde, hydrochloric acid, and gaseous hydrogen chloride showed that, in this case also, only the bischloromethyl derivative is formed, this, however, being accompanied by the mono(chloromethyl) derivative when cooling is applied. Finally, it must be pointed out also that in the chloromethylation of 2,5-di-tert-butylthiophene in acetic acid*, formation of the corresponding derivative of 3,3'-methylenedithiophene was again not observed, only the bischloromethyl derivative being isolated.

A different picture is observed when 2,5-dimethylthiophene is chloromethylated in presence of zinc chloride. In this case two crystalline substances are formed, one corresponding in composition to (III) and the other to 3,4-bis(2,5-dimethyl-3-thenyl)-2,5-dimethylthiophene (VI):

(VI)

* The chloromethylation of 2,5-di-tert-butylthiophene was studied in our Laboratory by M. L. Kimmalova.

However, the first of these compounds differed in melting point (48.5°) from the compound described by Buu-Hoi and Nghyen Hoan as 3,3'-methylenebis[2,5-dimethylthiophene], for which they obtained a melting point of 72°. This fact prompted us to seek other ways of preparing the compound (III), and the compound (VI) that accompanied it, with the object of making a comparison of properties. The scheme given below illustrates the results obtained:

in which DMT denotes 2,5-dimethylthiophene. From this scheme and the results given in the experimental part it will be seen that all of the methods selected for the preparation of the substituted methylenedithiophenes (III) and (VI) give identical compounds. Since the structure of one of the starting materials, 2,5-dimethyl-3-thiophenemethanol was established by an independent method (see above), the structure (III) for the product of m.p. 48.5° may be considered to be established.

As, however, the causes of the nonidentity of the melting points of our preparation and previously described preparations of 3,3'-methylenebis[2,5-dimethylthiophene] still remained obscure, we decided to prepare it by yet another method, in accordance with the scheme:

The first three stages of this process have been described by Buu-Hoi and Nghyen Hoan [11], and only the reduction of the ketone (IX) was carried out by us for the first time. We again obtained the compound of m.p. 48.5°, but at the same time we found some new discrepancies between constants observed by us and those given in the paper cited, namely those for the acid chloride (VIII) and the ketone (IX). The causes of these and previously mentioned discrepancies are at present obscure.

EXPERIMENTAL

1. Chloromethylation of 2,5-Dimethylthiophene with the aid of Formaldehyde and Hydrogen Chloride. A mixture of 10 g of 2,5-dimethylthiophene, 50 ml of concentrated hydrochloric acid, and 14 ml of 37% formaldehyde was prepared in a flask cooled in an ice bath, and a powerful current of hydrogen chloride was passed in for one hour. The temperature of the mixture gradually rose to 16°. At the end of one hour the reaction mixture was poured into ice water and extracted several times with benzene. The benzene extract was washed with water and dried over magnesium sulfate. Benzene was distilled off, and the residue was vacuum-distilled (13 mm), the following fractions being collected:

Fraction I, b.p. 98-135°; 6.7 g; colorless liquid, darkening in color when kept
Fraction II, b.p. 135-145°; 5.4 g; solid
Fraction III, b.p. 145-205°; 0.4 g; solid
Residue in flask 1.5 g

Refractionation of Fraction I gave 5.13 g of a substance boiling at 96-115° (13 mm) (the bulk of it came over at 98-102°). It was a colorless lachrymatory liquid, corresponding in analysis to the mono(chloromethyl) derivative. For the boiling point of 3-(chloromethyl)-2,5-dimethylthiophene the literature [3] gives 105-107° (20 mm).

	Found %:	C	52.65;	52.74;	H	5.54;	5.47
C_7H_9ClS.	Calculated %:	C	52.33;		H	5.61	

The solid of b.p. 135-145° (13 mm) (Fraction II) was recrystallized from heptane. The colorless crystals obtained melted at 67-68° and did not change with keeping. There was no melting-point depression in a mixture test with the substance obtained by the chloromethylation of 2,5-dimethylthiophene by means of paraformaldehyde and hydrogen chloride at 50° (see below).

From Fraction III, b.p. 145-205° and the residue in the flask, a substance of m.p. 144-157° was obtained by crystallization from heptane. The same product, although with a sharper melting point, was isolated in another experiment carried out under the same conditions apart from the amount of formaldehyde taken, which was doubled. After being recrystallized from acetone and heptane, the substance melted at 172-173°, and there was no melting-point depression in a mixture test with the product obtained by the chloromethylation of 3,3'-methylenebis[2,5-dimethylthiophene], m.p. 48.5°.

	Found %:	C	54.30;	54.14;	H	5.44;	5.46
$C_{13}H_{18}Cl_2S_2$.	Calculated %:	C	54.05;		H	5.40	

2, 2,5-Dimethyl-3-thiophenemethanol Acetic Ester. A mixture of 5.4 g of 3-(chloromethyl)-2,5-dimethylthiophene, 3 g of anhydrous sodium acetate, and 25 ml of glacial acetic acid was heated in a water bath at 60° for four hours. On the next day the precipitate of inorganic salt was filtered off and washed with acetic acid. Acetic acid was removed from the filtrate under reduced pressure, and water was added to the residue; the mixture was extracted several times with benzene. The combined benzene extracts of the reaction product were washed with water, benzene was distilled off, and the residue was vacuum-distilled. The product (3.8 g) was a colorless liquid, b.p. 125-128° (16 mm), n_D^{18} 1.5120.

	Found %:	C	58.62;	58.93;	H	6.44; 6.52;	S 17.15; 17.13
$C_9H_{12}O_2S$.	Calculated %:	C	58.69;		H	6.52;	S 17.40

3. 2,5-Dimethyl-3-thiophenemethanol. 2,5-Dimethyl-3-thiophenemethanol acetic ester (3.7 g) was added to a solution of 0.02 g of sodium in 30 ml of absolute alcohol. The mixture was kept at room temperature for 48 hours, and the alcohol was then distilled off under reduced pressure. The residue was dissolved in 30 ml of absolute alcohol and the solution was evaporated under reduced pressure to small bulk; carbon dioxide was then passed through the solution until it was saturated. The precipitate was filtered off and alcohol was distilled from the filtrate. Water was added to the residue, and the mixture was extracted with benzene. Benzene was distilled off, and vacuum distillation of the residue gave 2.1 g of a colorless liquid, b.p. 112-113° (10 mm) and n_D^{20} 1.5436, which became dark-colored on standing.

	Found %:	C	59.24;	59.44;	H	6.87; 6.88;	S 22.12
$C_7H_{10}OS$.	Calculated %:	C	58.15;		H	7.04;	S 22.53

Urethan. A mixture of 0.7 g of the alcohol and 0.6 g of phenyl isocyanate was heated in a water bath for 45 minutes. When cool, the reaction product solidified; it was recrystallized, first from hexane and then from gasoline (b.p. 60-90°). After being dried in a vacuum the urethan melted at 76-76.5°, and there was no depression in melting point in a mixture test with the urethan obtained from the alcohol prepared by the reduction of 2,5-dimethyl-3-thiophenecarboxaldehyde. For the melting point of the urethan derived from 2,5-dimethyl-3-thiophenemethanol the literature [3] gives 77-78°.

	Found %:	C	64.03;	64.29;	H	6.10; 5.97;	S	12.23; 12.22;	N 5.39
$C_{14}H_{15}NO_2S$.	Calculated %:	C	64.37;		H	5.75;	S	12.26;	N 5.35

4. Chloromethylation of 2,5-Dimethylthiophene with the aid of Paraformaldehyde and Hydrogen Chloride. A current of hydrogen chloride was passed through a mixture of 75 g of paraformaldehyde and 150 ml of concentrated hydrochloric acid at 50° until saturation was reached. Then - at the same temperature and with continued passage of a powerful current of hydrogen chloride - 27.5 g of 2,5-dimethylthiophene was added gradually to the mixture; when addition was complete the same reaction conditions were maintained for 90 minutes. When cool, the mixture was diluted with ice water. The reaction product was extracted several times with benzene. The benzene extract was washed with water, with 5% caustic potash solution, and again with water; it was then dried over calcium chloride. Benzene was distilled off, and the residue was vacuum-distilled. The bulk of the reaction product (41.2 g) came over at 130-142° (13 mm).

Recrystallization from heptane gave 34.3 g of a colorless substance, m.p. 67-68.5°. Recrystallization from heptane and hexane, and also sublimation in a current of nitrogen, did not affect its melting point.

	Found %:	C	46.20;	46.28;	H	5.02;	4.63;	Cl 33.35; 33.87
$C_9H_{10}Cl_2S$.	Calculated %:	C	45.93;		H	4.78;		Cl 33.97
	Found:	M	202					
	Calculated:	M	209					

3,4-Bischloromethyl-2,5-dimethylthiophene forms colorless crystals that remain unchanged in storage. It is soluble in benzene, ether, and acetone; less soluble in alcohol; sparingly soluble in cold heptane; and insoluble in water. It gives a precipitate of silver chloride with silver nitrate. 2,5-Dimethyl-3,4-thiophenedimethanol - which is obtained by the hydrolysis of its diacetic ester, which is itself prepared by the action of sodium acetate on 3,4-bischloromethyl-2,5-dimethylthiophene - is readily converted into 3,4-bischloromethyl-2,5-dimethylthiophene by shaking it with concentrated hydrochloric acid.

2,5-Dimethyl-3,4-thiophenedimethanol (0.8 g) was shaken with 8 ml of hydrochloric acid for 20 minutes. The mixture was then extracted with benzene. The benzene solution was washed, first with water, then with sodium bicarbonate solution, and then with water again. It was dried over magnesium sulfate. The benzene was distilled off, and 0.8 g of residue remained. Recrystallization from heptane gave 0.5 g, m.p. 67-68°, undepressed by admixture of 3,4-bischloromethyl-2,5-dimethylthiophene. Recrystallization of the 0.5 g from hexane gave 0.35 g, m.p. 67-68.5°.

5. Chloromethylation of 2,5-Dimethylthiophene with the aid of Chloromethyl Methyl Ether. A stirred mixture of 10 g of 2,5-dimethylthiophene, 14.4 g of chloromethyl methyl ether, and 30 ml of glacial acetic acid was maintained first at 0-10° for 30 minutes, and then at 23° for two hours. The reaction mixture was poured into iced water. The reaction product was extracted with benzene, and the extract was washed, first with water, then with saturated sodium bicarbonate solution, and then again with water. The solution was dried over magnesium sulfate, benzene was driven off, and the residue was vacuum-distilled, the following fractions being collected at 13 mm:

Fraction I, b.p. 96-98°; 7.6 g; colorless lachrymatory liquid
Fraction II, b.p. 110-150°; 2.5 g; which partially solidified
Fraction III, b.p. 155-184°; 1.2 g; a mixture of solid and oil
Residue in flask 1.7 g

Refractionation of Fractions I and II gave 7.3 g of a substance of b.p. 96-100° (13 mm) and a small amount of a substance of m.p. 66.5-67.5° (after recrystallization from heptane). We did not succeed in isolating a pure product from Fraction III. The product of b.p. 96-100° (13 mm) was a colorless lachrymatory liquid that darkened when kept. It had n_D^{20} 1.5482, and it was obtained in 51% yield.

6. Reaction between 3,4-Bischloromethyl-2,5-dimethylthiophene and 2,5-Dimethylthiophene in presence of Aluminum Chloride. A stirred mixture of 4.2 g of 3,4-bischloromethyl-2,5-dimethylthiophene, 5 g of 2,5-dimethylthiophene, 35 ml of carbon disulfide, and 0.2 g of aluminum chloride was maintained at room temperature for four hours and was then set aside overnight. On the next day carbon disulfide was distilled off, and water and benzene were added to the residue. The benzene layer was separated and washed, first with water, then with 5% sodium carbonate solution, and finally with water again. It was dried over magnesium sulfate. Benzene was distilled off, and 6.4 g of a solid residue was obtained which melted at 160-170° after recrystallization from heptane. When vacuum-distilled

(3-4 mm), the substance began to boil at about 200° and rapidly solidified in the side tube of the distilling flask. The product was dissolved in hot heptane, and on cooling the solution deposited colorless crystals, m.p. 174-175° (change began at 171°). A mixture test of these crystals with the substance of m.p. 174-175° obtained by the Friedel-Crafts condensation of 2,5-dimethylthiophene with 3-(chloromethyl)-2,5-dimethylthiophene showed no depression in melting point.

7. Condensation of 2,5-Dimethyl-3-thiophenemethanol with 2,5-Dimethylthiophene. A mixture of 2 g of 2,5-dimethylthiophene and 1.65 g of 2,5-dimethyl-3-thiophenemethanol was cooled with snow while addition was made of a mixture of equal weights of glacial acetic and concentrated sulfuric acids. The mixture was kept for two days at room temperature, and the reaction product, which had separated in the form of fine crystals, was filtered off. It was dissolved in hot heptane, and when the solution cooled 0.3 g of fine crystals separated. They were recrystallized from alcohol (the substance is sparingly soluble in hot alcohol), and they then melted at 170-173°. A mixture test with the substance of m.p. 174-175° obtained by reaction between 2,5-dimethylthiophene and 3-(chloromethyl)-2,5-dimethylthiophene in presence of aluminum chloride showed no depression in melting point.

	Found %:	C	66.35; 66.68;	H	6.57; 6.69	
$C_{20}H_{24}S_2$.	Calculated %:	C	66.66;	H	6.67	

In another experiment carried out under the same conditions we succeeded in isolating not only the above-described product, but also a small amount of a substance of m.p. 48°, which melted without depression when mixed with the substance of m.p. 48-48.5° isolated in the condensation reaction between 2,5-dimethylthiophene and 3-(chloromethyl)-2,5-dimethylthiophene.

8. Preparation of Substituted Methylenedithiophenes by the Friedel-Crafts Method. Aluminum chloride (0.2 g) was added to a mixture of 5.1 g of 2,5-dimethylthiophene, 7.3 g of 3-(chloromethyl)-2,5-dimethylthiophene, and 35 ml of carbon disulfide. The mixture was stirred for three hours at room temperature, and a further 0.3 g of aluminum chloride was added. On the next day the mixture was heated at 40-50° for 30 minutes. When cool, the mixture was decomposed with ice water, the carbon disulfide layer was separated from the aqueous layer, and the aqueous layer was extracted several times with benzene. The combined carbon disulfide and benzene solutions were washed with water and dried over calcium chloride. The solvents were distilled off, and the residue, a solid, was recrystallized from heptane. The crystals obtained (2.8 g) melted at 150-158° (incipient liquefaction began below this temperature). The heptane mother liquor was evaporated to small bulk. When it was cooled, crystals (1.5 g) of m.p. 42-46° separated; when the filtrate was evaporated a further 1.9 g was obtained. The product of m.p. 42-46° was vacuum-distilled; it boiled at 150° (6 mm). After repeated recrystallization from alcohol the distilled product melted at 48-48.5°. The substance was soluble in benzene, acetone, ether, hot alcohol, and hot heptane, but insoluble in water.

	Found %:	C	66.23; 66.41;	H	6.78; 6.82;	S	26.82; 26.85	
$C_{15}H_{18}S_2$.	Calculated %:	C	66.10;	H	6.77;	S	27.1	
	Found:	M	238					
	Calculated:	M	236					

The substance of m.p. 150-158° (2.8 g) (see above) was distilled at a residual pressure of 4 mm; it boiled at 195-207° and rapidly solidified in the side tube of the distilling flask, thus hindering distillation. After recrystallization from heptane the distilled product melted at 174-175° (change began at 172°).

	Found %:	C	66.74; 66.59;	H	6.84; 6.67;	S	26.29; 27.01	
$C_{20}H_{24}S_2$.	Calculated %:	C	66.66;	H	6.67;	S	26.66	
	Found:	M	351					
	Calculated:	M	360					

The substance was soluble in ether and benzene, and it was sparingly soluble in heptane and hot alcohol.

9. Chloromethylation of 2,5-Dimethylthiophene with the aid of Formaldehyde and Concentrated Hydrochloric Acid in presence of Zinc Chloride. Over a period of 15 minutes, 4.5 g of 37% formaldehyde was dropped into an ice-cooled mixture of 11.2 g of 2,5-dimethylthiophene, 5 g of concentrated hydrochloric acid (sp. gr. 1.18), and 10 g of anhydrous zinc chloride;

the mixture was stirred mechanically at the same temperature for 45 minutes and then at 60° for three hours. When the mixture was cool, water, benzene, and ether were added. The organic layer was separated from the aqueous layer, and the latter was extracted several times with ether and benzene. The combined benzene-ether extracts were washed several times with water, and the solvents were distilled off under reduced pressure. The residue, which partially crystallized out, was diluted with a little ether. The part of the reaction product that did not dissolve in the ether was filtered off and washed several times with small amounts of ether (ether filtrate A); 3.1 g of a colorless crystalline substance, m.p. 150-164°, was obtained. After recrystallization from alcohol and then from heptane it melted at 165-170° (change began at 158°). The substance was distilled at a residual pressure of 4 mm; it came over at 205-215° and rapidly solidified in the side tube of the flask. After recrystallization from acetone the distilled product melted at 170-172.5° (incipient liquefaction began at 167°). A mixture with the substance obtained from 2,5-dimethylthiophene and its bischloromethyl derivative melted at 170-174°. Ether was distilled from the ether filtrate (A). The residue was distilled at a residual pressure of 10 mm and gave the following fractions:

Fraction I, b.p. 157-165°; 3.8 g
Fraction II, b.p. 165-240°; 0.45 g
Residue in flask 1.3 g

Fraction I (3.8 g) was redistilled. The product (3.5 g of crystals) came over at 134-135° (4 mm). After recrystallization from heptane it melted at 48.5° and there was no depression in melting point in a mixture test with the product of m.p. 48° isolated in the condensation of 2,5-dimethylthiophene with its mono(chloromethyl) derivative in presence of aluminum chloride.

	Found %:	C	68.03; 68.07;	H	6.99; 6.97;	S	27.11; 27.28
$C_{12}H_{12}S_2$.	Calculated %:	C	68.10;	H	6.77;	S	27.11

10. Condensation of Benzyl Alcohol with 2,5-Dimethylthiophene. A mixture of 25 g of glacial acetic acid and 25 ml of concentrated sulfuric acid was added to an ice-cooled mixture of 5.6 g of 2,5-dimethylthiophene, 11 g of benzyl alcohol, and 50 ml of glacial acetic acid. The mixture was set aside for three days at room temperature and was then poured into ice water. The oil that separated was extracted with benzene. The benzene solution was washed with water, with 5% sodium carbonate solution, and then again with water. The benzene was distilled off, and vacuum distillation of the residue gave:

Fraction I, b.p. 60-120° (10 mm); 9.7 g
Fraction II, b.p. 130-160° (5 mm); 2.4 g
Fraction III, b.p. 160-190° (5 mm); 2.1 g

Fraction III was an immobile oil that partially crystallized out when kept in a refrigerator. The substance was dissolved in hot alcohol, and when the solution was cooled crystals of m.p. 68-69° (incipient melting at 67°) separated. In a mixture test with 3,4-dibenzyl-2,5-dimethylthiophene (see below) there was no depression of melting point.

11. Preparation of 3,4-Dibenzyl-2,5-dimethylthiophene. Anhydrous aluminum chloride (3.2 g) was added in small portions to a stirred ice-cooled solution of 5 g of the bischloromethyl derivative of m.p. 68° in 20 ml of dry benzene. After the addition of 10 ml of benzene, the mixture was set aside at room temperature for several hours and then decomposed with water and hydrochloric acid. The benzene layer was separated, and the aqueous layer was extracted with benzene. The combined benzene solutions were washed with water and with sodium carbonate solution. The benzene was distilled off, and vacuum distillation of the residue - a dark-red liquid - gave:

Fraction I, b.p. 118-120° (5 mm); 0.45 g
Fraction II, b.p. 187-191° (5 mm); 3 g (solid)
Fraction III, b.p. 191-220° (5 mm); a small amount of red oil

Recrystallization of Fraction II from alcohol gave 1.9 g of colorless crystals, m.p. 68-69°, unchanged by further crystallization.

	Found %:	C	82.64; 82.72;	H	6.82; 7.05;	S	11.32; 11.13
$C_{26}H_{26}S$.	Calculated %:	C	82.19;	H	6.85;	S	10.96

12. Chloromethylation of 2,5-Diethylthiophene. A powerful current of hydrogen chloride was passed into a mixture of 34 ml of 38% formaldehyde and 45 ml of concentrated hydrochloric acid until saturation was reached, and 2,5-diethylthiophene (10 g) was then added gradually at 30°. Hydrogen chloride was passed for a further two hours, and the mixture was then diluted with ice water and extracted with ether. The ether extract was washed with water and with a solution of sodium bicarbonate. It was dried over calcium chloride, ether was distilled off, and the residue was distilled at a residual pressure of 9 mm:

Fraction I, b.p. 128-134°; a small amount
Fraction II, b.p. 138-148°; 10.9 g (solid)

Recrystallization of Fraction II from heptane gave 6 g of a substance of m.p. 53°. The mother liquor yielded 2.6 g of a substance of m.p. 52-54°. After repeated recrystallization the melting point of the substance was 53-54°.

		Found %:	C	50.54; 50.67;	H	5.86; 5.75
$C_8H_{10}Cl_2S$.		Calculated %:	C	50.63;	H	5.91

3,4-Bischloromethyl-2,5-diethylthiophene is soluble in benzene and in hot alcohol; it is somewhat more difficultly soluble in heptane.

13. Chloromethylation of 2,4-Di-tert-butylthiophene. A mixture of 40 g of 37% formaldehyde, 20 ml of concentrated hydrochloric acid, and 100 ml of glacial acetic acid was saturated with hydrogen chloride gas, and 25.5 g of 2,5-di-tert-butylthiophene was then added gradually (over a period of 55 minutes) at 50-55°. After one hour at 50-55° and one hour at room temperature, the cooled mixture was poured into ice water. The reaction product separated in the form of crystals (39 g of crude product). The substance was found to be readily soluble in benzene, acetone, heptane, and hot acetic acid. After recrystallization from acetic acid, the substance melted at 86-86.5°. The yield of recrystallized product was 55%.

		Found %:	C	57.48; 57.46;	H	7.29; 7.35
$C_{14}H_{22}Cl_2S$.		Calculated %:	C	57.34;	H	7.51

No other individual products could be isolated in the chloromethylation of 2,5-di-tert-butylthiophene under the conditions described.

14. Reduction of 3,4-Bischloromethyl-2,5-dimethylthiophene. Stannous chloride (50 g) was mixed with 100 ml of acetic acid, and hydrogen chloride was passed to saturation, i.e. until the whole of the stannous chloride went into solution. The solution was filtered, and 10.4 g of the product of m.p. 68° obtained by the chloromethylation of 2,5-dimethylthiophene was added in small portions. The solution became slightly warm and gradually acquired a reddish-brown color. On the next day the mixture was poured into water. The greenish-yellow oil that separated was extracted with ether, and the extract was then shaken with caustic potash solution and with water. The extract was dried over calcium chloride and the ether was distilled off. Vacuum distillation of the residue gave 4.4 g of a substance having b.p. 75-78° (13-14 mm), n_D^{20} 1.5205.

		Found %:	C	68.63; 68.64;	H	8.47; 8.53; S 22.46; 22.76
$C_9H_{12}S$.		Calculated %:	C	68.57;	H	8.57; S 22.85

The product was unaffected by treatment with acetyl chloride in presence of stannic chloride.

15. Chloromethylation of 3,3'-Methylenebis[2,5-dimethylthiophene]. Freshly distilled chloromethyl methyl ether (3 g) was added to a cooled (ice water) solution of 3 g of the substance of m.p. 47-48° prepared by the chloromethylation of 2,5-dimethylthiophene with formaldehyde and hydrochloric acid in presence of zinc chloride. The mixture was heated for two hours in a water bath at 60°, and the crystalline precipitate formed was filtered off and washed with acetic acid. The crude product (4 g) melted at 167-169° (incipient melting at 155°). After being recrystallized from heptane the substance melted at 172.5-173°.

		Found %:	C	54.31; 54.48;	H	5.26; 5.37
$C_{15}H_{20}S_2Cl_2$.		Calculated %:	C	54.05;	H	5.40

16. Reduction of Bis(2,5-dimethyl-3-thienyl) Ketone. The following compounds were prepared by Buu-Hoï and Nghyen Hoan's method: the acid (VII), m.p. 116-117° (from aqueous alcohol); the acid chloride (VIII), b.p. 103-105° (12 mm); and the ketone (IX), m.p. 63-64° (from alcohol). The ketone

(IX) was synthesized also by Hartough and Kosak's method [12], namely by the action of phosphoric oxide on a mixture of the acid (VII) and 2,5-dimethylthiophene; the ketone obtained again melted at 63°. In the paper referred to above [11] the following constants are given: for the acid (VII) m.p. 117-118°, for the acid chloride (VIII) b.p. 144-145° (13 mm), and for the ketone (IX) m.p. 79°.

The 2,5-dimethylthiophene that we used for the synthesis of the ketone was prepared from 2-methylthiophene by King and Nord's method [5]. The sample so obtained was distilled through a 17-plate column and had b.p. 136.5° (754 mm), n_D^{20} 1.5134, and d_4^{20} 0.9880.

In another experiment on the preparation of the ketone we took 2,5-dimethylthiophene that had been synthesized from 2,5-hexanedione and distilled through a 17-plate column (it had b.p. 136.9° (760 mm), n_D^{20} 1.5127, and d_4^{20} 0.9859). The bis(2,5-dimethyl-3-thienyl) ketone prepared from this material again melted at 63-63.5°.

	Found %:	C	62.11; 62.19;	H	5.66; 5.65;	S	25.51; 25.59
$C_{13}H_{14}OS_2$.	Calculated %:	C	62.40;	H	5.60;	S	25.60

Hydrazine hydrate (100%, 2.7 ml) was added to a mixture of 3.7 g of the ketone and 30 ml of diethylene glycol contained in a three-necked flask fitted with stirrer, reflux condenser, and thermometer. After 25 minutes at room temperature 3 g of caustic potash was added to the mixture, which was then heated for about one hour in a metal bath at 133-134°. A condenser set for distillation was then attached to the flask, and heating was continued until the temperature reached 195° (about two hours). The mixture was maintained at this temperature for three hours. When cool, it was diluted with ice water. The solid that then separated was filtered off, washed with water, and dried. Vacuum distillation of this gave 1.5 g of crystals, b.p. 172° (13 mm). Recrystallization of the product from alcohol gave 1.1 g of m.p. 47-48°, unaffected by repeated crystallization from alcohol. A mixture test of this substance with the substance of the same composition (m.p. 48°) obtained in a different way (see the first scheme, above) showed no depression in melting point.

SUMMARY

1. A study was made of the chloromethylation of 2,5-dimethylthiophene with a mixture of formaldehyde and hydrochloric acid and with chloromethyl methyl ether. The presence of the compound of m.p. 72° described by Buu-Hoi and Hoan could not be detected among the reaction products.

2. In the chloromethylation of 2,5-dimethylthiophene in presence of zinc chloride, compounds were formed which corresponded in composition to 3,3'-methylenebis[2,5-dimethylthiophene] and 3,4-bis(2,5-dimethyl-3--thenyl)-2,5-dimethylthiophene. These compounds were obtained also when 2,5-dimethylthiophene reacted with 3-(chloromethyl)-2,5-dimethylthiophene in presence of aluminum chloride and when 2,5-dimethylthiophene reacted with 2,5-dimethyl-3-thiophenemethanol in presence of sulfuric acid.

3. The compound of m.p. 48.5° was obtained also by the reduction of bis(2,5-dimethyl-3-thienyl) ketone.

4. By the chloromethylation of 2,5-diethylthiophene and of 2,5-di-tert-butylthiophene under selected conditions, the corresponding dialkylbischloromethylthiophenes were obtained. The formation of substituted methylenedithiophenes was not observed under these conditions.

BRIEF COMMUNICATIONS

ION EXCHANGE ON CELLULOSE AND ITS DERIVATIVES

V. I. Ivanov and N. Ya. Lenshina

Celluloses, natural and isolated from plant tissues, are able to absorb cations from solutions of neutral salts. Various authors [1-3] have shown that, when cellulose is immersed in a salt solution, the solution becomes acid. Ion exchange on cellulose is now acquiring great theoretical and practical importance. Little progress has yet been made in the elucidation of the source of the exchange properties of cellulose. Some authors [4, 5] consider that ion exchange on cellulose results from the presence of inorganic substances (ash). Others [6, 7] consider that it results from the presence of noncellulosic components (pectic substances, etc.). It is coming to be considered that the exchange properties of cellulose are properties of the cellulose itself, and on this basis investigations are being made of celluloses that are free from inorganic cations and are capable of ion exchange. In a series of investigations it was shown [8] that the ion-exchange properties are dependent on the acidic nature of the cellulose; the authors consider that the acidic properties of cellulose may be intensified in the process of isolation from natural materials.

Sookne and Harris [9] investigated various samples of cotton cellulose, which were freed from inorganic substances or from pectic materials. Their investigations showed that, apart from the COOH groups belonging to pectic substances, cellulose itself contains COOH groups. They found that the exchange capacity of cellulose freed from inorganic substances was 0.066 mg.equiv./g, the capacity of cellulose freed from pectic substances was 0.011 mg.equiv./g, whereas the capacity of the original cellulose was 0.046 mg.equiv./g. Exchange attributable to cations of inorganic substances did not exceed 0.004 mg.equiv./g. Other authors [10, 11] state that COOH groups in oxidized celluloses react with multivalent cations with formation of salts of "cellulose acid". A series of papers [12-14] refer to the ion-exchange properties of oxidized celluloses. The availability of more precise chemical methods now enable the COOH content of cellulose to be determined. It has been found that the COOH content of cellulose prepared according to Corey and Gray is 0.004 mg.equiv./g, that of medicinal cotton wool is 0.02 mg.equiv./g [8], and that of sulfate cellulose is 0.072 mg.equiv./g [7].

No cellulose has yet been isolated which does not contain COOH groups. Analysis of the purest celluloses has shown that they contain 2-3 COOH groups per 1000 glucose residues [15]. If the COOH groups were to be found only in the residues of substances accompanying cellulose, as some authors think [6, 7], then they could not be concerned in the rapid change in the rate of the depolymerization of cellulose that occurs during the first few minutes of its treatment with acid solutions. It is therefore considered that these functional groups belong to particular units of the cellulose macromolecule. This can be expressed diagrammatically by the following formula [16]:

The dots indicate unchanged glucose residues (anhydro-D-glycose).

It has not been found possible to establish whether or not COOH groups are present in the molecule of cellulose before its isolation from the plant. Cellulose with which we have to deal in practice, and also cellulose intended for precise chemical investigations, will always contain functional groups other than OH groups and terminal CHO groups. The presence of COOH groups, even in very small amount, has a great effect on the properties of cellulose and of articles prepared from it. The question of the ash obtained from cellulosic materials is important, for the presence of inorganic substances affects the viscosity, insulation properties, dyeability, etc., of cellulose [5, 6]. On the basis of this it may be supposed that ion exchange on cellulose free from inorganic ion-exchange cations occurs as a result of the presence of COOH groups. With the object of elucidating this matter we have begun an investigation on the ion-exchange properties of cotton cellulose and oxidized celluloses having various COOH contents. The COOH contents were determined by the calcium acetate method [17-19].

The solutions selected for trial were 0.005 M $NiCl_2$ and 0.005 M $FeCl_3$. The solutions were passed through a column of cellulose (as cationite) at 3 ml per sq.cm per minute, the height of the column being 100 mm and its diameter 10 mm. The total exchange capacity was determined from the difference in cation concentration between the ingoing solution and the effluent. The process was continued until the cation concentration in the effluent was equal to that in the ingoing solution. The effluent was collected in 25 ml portions. The absorption of Ni^{2+} was carried out from a solution of pH 6.6, and that of Fe^{3+} was carried out from a solution of pH 1.4. In both cases absorption attained the value of the total exchange capacity. The experimental results for the absorption of Ni^{2+} and Fe^{3+} by cellulose and oxidized celluloses are given in the table, the values given being the means of groups of several determinations.

TABLE

Absorption of Ni^{2+} and Fe^{3+} by Cotton Cellulose and Oxidized Celluloses

Cellulose preparation	COOH content (mg.equiv./100 g of sample	Absorption of	
		Ni^{2+} (mg.equiv./100 g of sample)	Fe^{3+} (mg.equiv./100 g of sample)
Cotton cellulose	1.5	1.3	50
Oxidized cellulose			
1	56	53	43
2	220	200	58
3	280	215	46

As will be seen from the table, the absorption of Ni^{2+} from neutral solution can be correlated with the COOH content of the sample. The behavior of Fe^{3+} is quite different: the absorption is approximately the same for all of the samples, being about 50 mg.equiv./100 g. It follows that the absorption of Fe^{3+} by cellulose has a different mechanism than that of Ni^{2+}. The difference in the behavior of Fe^{3+} is of general interest in relation to the elucidation of the mechanism by which metal hydroxides are absorbed by cellulose.

Since ion exchange on cellulose occurs in many processes and affects the properties of cellulose and of articles prepared from it, we have undertaken a more detailed study of the matter. Cellulose is extensively applied also in chromatography. In addition to the separation of amines, amino acids, and other organic substances by the methods of partition chromatography, the separation of these substances by ion-exchange methods now finds application [20-23]. The study of ion exchange will throw new light on problems in chromatography on cellulose and its derivatives, and it will also enable us to determine the dependence of the properties of cellulose on the presence in it of various cations. Work in this field is continuing.

SUMMARY

1. Ion exchange on cellulose free from inorganic ion-exchange cations is the result of the presence of COOH groups.

2. The mechanism of the absorption of Fe^{3+} ions by cellulose is different from that of the absorption of Ni^{2+} ions.

ORGANOBORON COMPOUNDS

COMMUNICATION 9. ACTION OF PHOSPHORUS PENTACHLORIDE ON DIALKYLBORINIC AND ALKANEBORONIC ESTERS. SYNTHESIS OF DIALKYLCHLOROBORINES AND ALKANECHLOROBORONIC ESTERS

B. M. Mikhailov and T. A. Shchegoleva

Dialkylborinic esters react with phosphorus pentachloride with formation of dialkylchloroborines (dialkylborinic chlorides), alkyl halides, and phosphoryl chloride:

$$RR'BOC_4H_9 + PCl_5 \rightarrow RR'BCl + C_4H_9Cl + POCl_3.$$

By this method butyl dibutylborinate was converted into dibutylchloroborine $(C_4H_9)_2BCl$, and butyl butylpropylborinate was converted into chlorobutylpropylborine:

Dibutylchloroborine has been prepared previously by the action of hydrogen chloride on tributylborine [1]. Compounds of this type containing two different alkyl radicals have not been described previously.

Alkaneboronic esters react equally smoothly with phosphorus pentachloride, and, when one equivalent of phosphorus pentachloride is used, alkanechloroboronic esters are obtained in accordance with the equation:

In this way we prepared butyl esters of 1-butanechloroboronic and 1-propanechloroboronic acids, these being the first representatives of a new type of compounds in which boron is attached simultaneously with an alkyl group, an alkoxy group, and a chlorine atom.

EXPERIMENTAL

All operations were carried out in a nitrogen atmosphere.

Dibutylchloroborine. Phosphorus pentachloride (17.6 g) was added in portions to butyl dibutylborinate (16.8 g) contained in a three-necked flask fitted with an entry tube for nitrogen and a reflux condenser. When the exothennic reaction was complete, butyl chloride and phosphoryl chloride were distilled off under reduced pressure and were collected in a receiver cooled with solid carbon dioxide. The residue was then distilled and yielded 12 g (89%) of dibutylchloroborine, b.p. 58-60° (12 mm). After redistillation the substance boiled at

59.5-60° (12 mm) and 172-174° (atmospheric pressure). The literature [1] gives b.p. 173° and d_4^{20} 0.8590. The substance bursts into flame in the air.

Found %: B 6.75; Cl 22.53
$C_5H_{12}BCl_2$. Calculated %: B 6.74; Cl 22.09

The butyl chloride and phosphoryl chloride were also isolated.

Butylchloropropylborine. The procedure was similar to that of the preceding experiment. Reaction was between 13.3 g of butyl butylpropylborinate [2] and 15 g of phosphorus pentachloride. The product, amounting to 5.1 g (50%), was butylchloropropylborine, b.p. 57-61° (28 mm). After being redistilled it had b.p. 60-61° (28 mm) and d_4^{20} 0.8503. The substance bursts into flame in the air.

Found %: B 7.27; Cl 24.55
$C_5H_{12}BCl_2$. Calculated %: B 7.39; Cl 24.21

The butyl chloride and phosphoryl chloride were also isolated.

Butyl 1-Butanechloroboronate. The procedure was similar to that of the preceding experiment. Reaction was between 20.2 g of dibutyl 1-butaneboronate and 19.6 g of phosphorus pentachloride. The product, amounting to 12.8 g (78%), was butyl 1-butanechloroboronate, b.p. 68-70° (13 mm). After being redistilled it boiled at 64-65° (10 mm) and had d_4^{20} 0.9025.

Found %: B 6.27; Cl 20.03
$C_8H_{18}BOCl$. Calculated %: B 6.13; Cl 20.09

In addition, 8.5 g of butyl chloride and 8.7 g of phosphoryl chloride were isolated.

Dibutyl 1-Propaneboronate. An ethereal solution of propylmagnesium chloride prepared from 36 g of magnesium, 116 g of propyl chloride, and 600 ml of ether was added at −70° to a solution of 160 g of trimethyl borate in 400 ml of ether. The reaction mixture was decomposed with 10% hydrochloric acid, and solvent was distilled from the ether layer. Butyl alcohol (400 ml) was added to the residue. Distillation removed the azeotropic mixture of butyl alcohol and water and then the remainder of the butyl alcohol, and the residue was then fractionally distilled. The product, amount to 132 g (44%), was dibutyl 1-propaneboronate, b.p. 86-90° (10 mm). After being redistilled the ester had b.p. 82-83° (7 mm) and d_4^{20} 0.8152.

Found %: B 5.57
$C_{11}H_{25}BO_2$. Calculated %: B 5.41

Butyl 1-Propanechloroboronate. The procedure was similar to that of the first experiment. Reaction was between 20.7 g of dibutyl 1-propaneboronate and 21.5 g of phosphorus pentachloride. The product, amounting to 14 g (83%), was butyl 1-propanechloroboronate, b.p. 59-67° (25 mm). After being redistilled it had b.p. 60.6-61° (22 mm) and d_4^{20} 0.8999.

Found %: B 6.83; Cl 22.15
$C_7H_{16}BOCl$. Calculated %: B 6.66; Cl 21.82

The butyl chloride and phosphoryl chloride were also isolated.

SUMMARY

1. Dialkylborinic esters react with phosphorus pentachloride with formation of dialkylchloroborines.

2. Alkaneboronic esters react with phosphorus pentachloride with formation of alkanechloroboronic esters.

TERTIARY ALKYL FLUORIDES AND ALKYLENE DIFLUORIDES IN ORGANOMAGNESIUM SYNTHESIS

A. D. Petrov, V. L. Sushchinsky, and M. P. Shebanova

It is known that alkyl fluorides either do not form Grignard reagents or form them in negligible yield, even if very severe conditions are used [1]. We recently condensed tertiary mono- and di-chloro compounds with halogen compounds of the allyl halide type in presence of magnesium, following Yarovsky's method [2]. We showed that, under the given conditions, even halogen compounds that were unable to form Grignard reagents owing to peculiarities in the structure of their radicals entered into the condensation reaction with formation of olefins, although the yields were generally low. Taking into consideration the fact that the C–F bond energy (102 cal/mole) is considerably higher than the C–Cl bond energy (77.9 cal/mole), we decided to study the condensation reaction of tertiary alkyl fluorides and alkylene difluorides whose chlorine analogs had already been investigated. The results, which are shown in Table 1, indicate that our calculations were justified and that the replacement of chlorine by fluorine in alkyl and alkylene chlorides raises the yield by a factor of 2.5-3. Reaction with the monofluoro compounds was carried out in boiling ether, and reaction with difluoro compounds was carried out at −30°. In view of the high mobility of fluorine in alkyl fluorides [3], the fluoro compounds were prepared from olefins (and diolefins) and hydrogen fluoride at low temperature (−20 to −30°) and were not distilled, being used in the condensation with allyl halides in admixture with the original hydrocarbons.

The properties of the hydrocarbons obtained, together with values from the literature for comparison, are given in Table 2. It is interesting to note that high yields of hydrocarbons containing two quaternary carbons were attained as a result of the high energy of the C–F bond, which enabled the condensation reaction to be carried out rapidly both at +40° and at −30°. It is interesting to note also that, as a side reaction, diolefins are formed from difluoro compounds just as they are from dichloro compounds (this reaction was carried out at −20°) and from dibromo compounds (reaction proceeded only at +35°). In the last case it was not the dibromo compound that reacted, but a monobromo compound that had undergone allyl rearrangement.

EXPERIMENTAL

The hydrofluorination of the olefins (and diolefins) was carried out in a copper reactor fitted with stirrer, thermometer, and copper reflux condenser, through the upper open end of which dry ice and acetone were added. The reactor was placed in a cooling mixture maintained at −40°. Liquid anhydrous hydrogen fluoride was poured into the cooled reactor. The olefin (or diolefin) was then introduced from a dropping funnel and then through the condenser at such a rate that the temperature of the reaction mixture did not exceed −30° (the temperature in the condenser jacket was kept at −25°). When reaction was complete, the excess of hydrogen fluoride was removed with a current of nitrogen at 0-10°. Analysis for fluorine showed that the yields of tertiary monofluoro compounds varied from 30 to 60% and the yield of the difluoro compound was 22%. A difluoro compound was obtained from the diolefin corresponding to the pinacol from the branched ketone isobutyl methyl ketone in a yield of only 10%, but the corresponding dichloro compound could not be obtained at all. The undistilled fluoro compounds in admixture with the original hydrocarbons and the second component of the synthesis was added to magnesium in ether under the usual conditions of the Yarovsky procedure at the temperatures indicated above. The reaction products were decomposed in the usual way and then fractionated. The diolefin (VI) was oxidized with 3% potassium permanganate, and formic acid and 3,4-diethyl-3,4-dimethylhexanedioic acid were identified among the products.

TABLE 1

(VI)	88.23	14.04	86.6	13.4	146 (145) 210 (760)	1.4625 1.4620	0.8205 0.818	[6]

Found %: Ag 48.08; C 62.46; H 10.25

$C_{12}H_{23}O_6$. Calculated %: Ag 48.64; C 62.61; H 9.57

The properties of 3,4-dibromo-3,4-dimethylhexane, obtained by the action of HBr on the corresponding diolefin were: b.p. 85-87° (5 mm); n_D^{20} 1.5060; d_4^{20} 1.387.

Found %: Br 58.76; C 36.60; H 6.98

$C_8H_{16}Br_2$. Calculated %: Br 58.82; C 35.04; H 5.84

When the condensation product obtained from this dibromo compound and excess of allyl chloride was fractionated, only a diolefin of composition $C_{11}H_{20}$ was isolated; b.p. 176-178° (750 mm); n_D^{20} 1.4530; d_4^{20} 0.8002.

Found %: C 86.47; H 13.17

$C_{11}H_{20}$. Calculated %: C 86.84; H 13.16

The following substances were identified among the oxidation products of this hydrocarbon: 2-butanone, formic acid, and 2-methyllevulinic acid. This shows that the diolefin is 4,5,6-trimethyl-1,5-octadiene, which has been prepared previously [6].

SUMMARY

It was shown that, when chlorine is replaced by fluorine in tertiary alkyl halides and alkylene dihalides, the yield in the condensation of these substances with Grignard reagents is increased by a factor of 2.5-3.

RAPID NONIONIC METATHETIC REACTIONS IN A NONAQUEOUS MEDIUM

Yu. M. Kessler

In the course of a study of the physicochemical properties of solutions of mercury and tin halides in benzene and in nitrobenzene we found that halogen exchange occurred between $Hg(Hal)_2$ and SnI_4 (Hal = Cl, Br) in the solutions $Hg(Hal)_2 - SnI_4 -$ solvent with formation of HgI_2. This reaction occurred when the solid salt $Hg(Hal)_2$ was added to a benzene or nitrobenzene solution of SnI_4 at room temperature. The mixture was shaken, and as soon as most of the $Hg(Hal)_2$ had dissolved, fine yellow crystals began to form throughout the whole solution and were precipitated. The crystals gradually became red in color (in about one hour). The precipitate was identified as HgI_2 by analysis and by the occurrence of a transformation at 127° [1, 2]. The amount of precipitate formed corresponded to the amount of HgI_2 formed by the reaction.

$$SnI_4 + 2Hg(Hal)_2 \rightarrow Sn(Hal)_4 + 2HgI_2 \qquad (1)$$

allowance being made for the solubility of HgI_2 under the given conditions.

A study of the kinetics of the evaporation of solvent from solutions of $HgCl_2$, $HgBr_2$, HgI_2, and SnI_4 in benzene showed that these solutions conform to Raoult's law right up to the saturation point and that, when saturation is reached, the halides crystallize without solvent.* Conductivity measurements on these solutions showed that they have the same conductivity as pure benzene ($\chi < 10^{-8}$ ohm^{-1}cm^{-1}), and it was shown that the same applied to solutions of the type $Hg(Hal)_2 - SnI_4 - C_6H_6$ (after the precipitate had formed) and $HgI_2 - SnI_4 - C_6H_6$.

The literature indicates that with nitrobenzene mercuric chloride forms an incongruently melting compound [4], whereas mercuric bromide [4] and iodide [2] form simple eutectics. There are no data for stannic chloride. We have shown that these halides form conducting solutions in nitrobenzene, the specific conductance in 0.1 mole percent solution at 30° being: $HgCl_2 - 2.0 \cdot 10^{-6}$; $HgBr_2 - 1.2 \cdot 10^{-6}$; $HgI_2 - 1.2 \cdot 10^{-6}$; and $SnI_4 - 4.3 \cdot 10^{-5}$ (ohm^{-1}cm^{-1}). Addition of mercuric iodide to an SnI_4 solution increases its conductivity, which reaches a maximum value of $1.3 \cdot 10^{-4}$ ohm^{-1}cm^{-1} at a molar ratio $HgI_2 : SnI_4$ of 0.1 and is almost unaffected by further increase in the ratio. As HgI_2 is added, the color of the solution changes from deep crimson to pink. Addition of $HgCl_2$ or $HgBr_2$ to $SnI_4 - C_6H_5NO_2$ solutions alters their conductivities (measured after the precipitation of HgI_2) to the corresponding values for the solutions $HgI_2 - SnI_4 - C_6H_5NO_2$.

The color of a nitrobenzene solution of SnI_4 changes reversibly from dark crimson to reddish orange when the temperature is raised to 60-70°, and its conductivity rises until saturation is reached (at 30°). When the solution $HgI_2 - SnI_4 - C_6H_5NO_2$ was electrolyzed (p.d. across cell 5 v, current 10^{-4} amp), a compact layer of HgI_2 was formed on the anode and the liquid near to the cathode acquired a reddish-violet color. These results indicate the occurrence of complex formation in the solution.

In spite of the great difference in the properties of the benzene and nitrobenzene solutions, the apparent courses of the mercuric iodide precipitation reactions are the same in both solvents. This probably indicates that the molecular interaction in nitrobenzene is insufficient to have an appreciable effect on the properties of the halide molecules that determine the course of the reaction. It is notable that the rate of reaction is of the same order as that of ion-exchange reactions, in spite of the complete absence of ions in the benzene solu-

* By means of ebullioscopic measurements, Walden [3] showed that a benzene solution of SnI_4 in benzene has van't Hoff factor $i = 1$.

tions (conductivity data) and of I^- ions in nitrobenzene solutions (electrolysis data). This is especially notable when it is considered that even the isotopic exchange $Br_2^* \rightleftharpoons HgBr_2$ (in carbon disulfide) requires 2.5 minutes [5], though it is true that the iodine in SnI_4 is considerably more mobile, the exchange $I_2^* \rightleftharpoons SnI_4$ in CCl_4 at 0° requiring less than 7 seconds [6]. The only reactions that we know which somewhat resemble those now under consideration are those resulting in the formation of $GeClBr_2I$ and $GeCl_2BrI$ in $GeCl_4 - GeBr_4 - GeI_4$ mixtures, the existence of these compounds being established by a Raman-spectrum study of the mixtures [7], and also that leading to the formation of $SnCl_2I_2$ according to the equation

$$SnCl_4 + SnI_4 \rightleftharpoons 2SnCl_2I_2, \qquad (2)$$

the formation of this compound in an $SnCl_4 - SnI_4$ mixture being established by cryoscopic and ebullioscopic measurements [8]. An attempt to isolate $SnCl_2I_2$ by cooling the mixture or evaporating admixed solvent was not successful [8]. Taking this work into consideration, we may suppose that in our case reaction does not proceed in accordance with Equation 1, its actual course being represented by the equation:

$$SnI_4 + Hg(Hal)_2 \rightarrow Sn(Hal)_2I_2 + HgI_2. \qquad (3)$$

It will be obvious that calculations of the amount of precipitate from Equation 1 and from Equation 3 will give identical results, since the stoichiometric coefficients of $Hg(Hal)_2$ and HgI_2 are equal in both cases.

The precipitation of mercuric iodide as a yellow modification that is unstable at room temperature can be related to the structure of its molecule and the structures of the two modifications. Mercuric iodide molecules are linear (in the vapor). In crystals of the red modification, each mercury atom is surrounded tetrahedrally by four iodine atoms [9]. The yellow modification crystallizes in the $HgBr_2$ structure, in which there are linear $HgBr_2$ molecules and each mercury atom has two bromine atoms as closest neighbors and four more at a greater distance, forming altogether a highly distorted octahedron; the respective distances in the yellow modification of HgI_2 are 2.62 and 3.46 A [10]. It may be supposed that the crystallization of the unstable yellow modification from solution is associated with the tendency to preserve the linear configuration of HgI_2 molecules. We may point out that, when HgI_2 that has been heated above the transition temperature is cooled in the air, the yellow modification can be preserved at room temperature for more than one hour without its being converted into the stable modification (according to our own experiments).

Owing to the absence of the necessary thermochemical data, we were unable to estimate the heats of the reactions under discussion. The existing data are, however, sufficient to show that the reactions must be appreciably exothermic.

In conclusion we may state our opinion that the reactions described, being examples of very rapid reactions, present considerable interest for the theory of the transition state (see e.g. [11]) and also from the point of view of their molecular mechanism. We plan to carry out thermochemical and kinetic studies of these reactions.

The author expresses his great indebtedness to A. F. Kapustinsky for valuable suggestions made during the discussion of this work.

SUMMARY

1. Studies were made of the electrical conductivities of ternary mixture of $Hg(Hal)_2$ (Hal = Cl, Br), SnI_4, and benzene or nitrobenzene and of the kinetics of evaporation of solvent from the binary mixtures $Hg(Hal)_2$ — benzene and SnI_4 — benzene.

2. It was shown that in $Hg(Hal)_2 - SnI_4$ — solvent mixtures, instantaneous halogen exchange occurs with formation of HgI_2.

3. It was shown that this exchange is not associated with the presence of ions or stable complexes in the solutions and does not depend on the difference in properties between the solvents used.

REACTION OF DEUTERIUM ATOMS WITH ALKENES

DEPENDENCE OF THE EXTENT OF THE DEUTERATION OF METHANE ON THE CONCENTRATION OF DEUTERIUM ATOMS IN THE SYSTEM

R. E. Mardaleishvili, G. B. Parilsky, V. A. Poltorak, and V. V. Voevodsky

In the foreign literature it is considered that there is general agreement on the correctness of the view that the formation of highly deuterated products by reaction between deuterium atoms and molecules and various organic compounds is the result of an exchange reaction occurring between free radicals formed under the given conditions and deuterium atoms [1, 2]. For methyl radicals, for example, the exchange is generally expressed as follows:

$$\left.\begin{aligned} \dot{C}H_3 + D &\rightleftharpoons \dot{C}H_2D + H \\ \dot{C}H_2D + D &\rightleftharpoons \dot{C}HD_2 + H \end{aligned}\right\} \quad (1)$$

and so on.

In our first investigation [3] we established that exchange between radicals and deuterium, at least when the radicals are generated by interaction between alkenes and hydrogen (H or D) atoms formed by the dissociation of hydrogen (H_2 or D_2) in a discharge tube, involves deuterium molecules, not deuterium atoms. Hence, in the exchange reaction of methyl radicals which we have taken as an example, the process must be expressed as follows:

$$\left.\begin{aligned} \dot{C}H_3 + D_2 &\rightleftarrows H-\overset{\displaystyle H}{\underset{\displaystyle H-D}{\overset{|}{\underset{|}{C}}}}-D \rightleftarrows \dot{C}H_2D + HD \\ \dot{C}H_2D + D_2 &\rightleftarrows D-\overset{\displaystyle H}{\underset{\displaystyle H-D}{\overset{|}{\underset{|}{C}}}}-D \rightleftarrows \dot{C}D_2H + HD \end{aligned}\right\} \quad (2)$$

Owing to the high velocity with which processes of the type (2) occur, the phenomenon of exchange can be applied as a new method for the identification of free radicals. For example, this method has been applied [4, 5] in demonstrating that some free radicals undergo isomerization with migration of the free valency:

$$\text{—}\dot{C}H\text{—}CH_2\text{—}CH_2\text{—} \rightleftharpoons \text{—}CH_2\text{—}CH_2\text{—}\dot{C}H\text{—} \qquad (3)$$

In particular, it was shown in this investigation that extensive exchange with the reaction products is observed even when radicals are generated in the system [(H + H_2 + Ar) + alkene] + D_2 (i.e. when the alkene is admixed with the stream before the admixture of deuterium). Under these conditions the formation of deuterium atoms by the reaction

$$H + D_2 \rightleftharpoons HD + D \qquad (4)$$

cannot occur, for hydrogen atoms are absent at the point at which deuterium is added to the stream because of the occurrence of the reactions

$$H + \text{alkene} \longrightarrow \dot{R}$$

$$H + \dot{R} \longrightarrow \dot{R}_1 + \dot{R}_2;$$

$$H + H + M \longrightarrow H_2 + M^*;$$

in which substantially the whole of the hydrogen atoms are consumed. This result confirms the conclusion reached previously, namely, that the exchange of the hydrogen atoms of radicals for deuterium is the result of reaction between these radicals and deuterium molecules [3].

The present investigation had the object of studying the part played by deuterium atoms in the deuteration of the products and it has not only given results that are of interest on their own account, but has provided new data in confirmation of the occurrence of exchange between radicals and D_2 molecules. We considered it to be especially desirable to give these data in the present paper because Steacie [2], in an examination of the results of our first investigation in his recently published extensive monograph, expressed doubts, for which he gave no grounds, with regard to the feasibility of the exchange mechanism that we suggested.

EXPERIMENTAL

1. In planning this investigation we considered that a study of the dependence of the yield and extent of deuteration of the products on the concentration of D atoms would enable us to establish, first, the part played by D atoms in the formation of and exchange with particular radicals and, second, the part played by D atoms and by various radicals formed by their aid in the formation and deuteration of the products. With this in view, we investigated the deuteration of methane formed in (D + D_2) + alkene systems (the alkene being C_2H_4, C_3H_6, or i-C_4H_8) at various concentrations of deuterium atoms and particularly at [D] $\longrightarrow$ 0.

Let us examine the question of the deuteration of methane formed at extremely low concentrations of deuterium atoms, since this procedure enables us to decide which of the two exchange mechanisms — atomic or molecular — should be used in the analysis of the results obtained in experiments at high concentrations of D atoms. The deuteration of methane at [D] $\longrightarrow$ 0 must proceed differently according as exchange with free radicals occurs predominantly in interaction with atoms or with molecules of deuterium. In both cases the extent of the deuteration of methane can be calculated.

a) (α_{D_M})$_{[D]\to 0}$ — in accordance with the atomic exchange scheme. The most probable mechanism of methane formation, e.g. in the system (D + D_2) + C_2H_4, under our experimental conditions (pressure in the gas stream about 1 mm, t = 20-25°) is as follows:

$$\begin{aligned}
&0.\quad D + C_2H_4 \rightarrow CH_2D - \dot{C}H_2\\
&1.\quad CH_2D - \dot{C}H_2 + D \rightarrow 2\,\dot{C}H_2D\\
&2.\quad \dot{C}H_2D + CH_2D - \dot{C}H_2 \rightarrow \begin{cases} {}^{1}/_{2}\{CH_2D_2 + CH_2 = CH_2\} \\ {}^{1}/_{2}\{CH_3D + CHD = CH_2\} \end{cases}
\end{aligned} \qquad (5)$$

The reactions

$$3.\ \dot{C}H_2D + D + M \rightarrow CH_2D_2 + M^*$$
$$4.\ \dot{C}H_2D + D_2 \rightarrow CH_2D_2 + D,$$

by which methane can also be formed, are unable to compete with reaction (5, 2): reaction (5, 3) cannot compete because of the insignificant concentration of D atoms in the system (for $[D] \rightarrow 0$) and the need for three-body collisions, and reaction (5, 4) cannot compete because of the activation energy required (8 kcal; $E_2 \approx 0$). These reactions, therefore, need not be taken into consideration. We do not take account also of the possibility of the isotope-exchange reaction

$$\dot{C}H_2D + D \rightleftarrows \dot{C}HD_2 + H,$$

since at $[D] \rightarrow 0$ it cannot occur at an appreciable rate owing to the fact that, under these conditions, almost all of the D atoms are used up in the reaction (5, 0).

It may be considered, therefore, that methane is formed exclusively by reaction (5, 2), and the extent of its deuteration should not then exceed

$$(\%\,D_M)_{[D]\rightarrow 0} = \frac{{}^1/_3 \times 2 + {}^2/_3 \times 1}{4} \times 100 = 33\%$$

b) $(\%\,D_M)_{[D]\rightarrow 0}$ — in accordance with the molecular exchange scheme. In this case the mechanism of the formation of $\dot{C}H_2D$ radicals is the same as that given above. Owing to the presence in the system of D_2 molecules in large excess over the amount of methyl radicals, the latter undergo exchange until an equilibrium mixture of radicals

$$\dot{C}D_3 + \dot{C}D_2H + \dot{C}HD_2 + \dot{C}H_2D,$$

is formed which we shall denote by $C\mathcal{D}_3$. Similar exchange will be undergone by other radicals formed in the system, for example

$$CH_2D—\dot{C}H_2 \xrightarrow{D_2} CH_2D—C\mathcal{D}_2.$$

Disproportionation of deuterated methyl radicals by a reaction of the type (5, 2), i.e. in the present case the reaction

$$C\mathcal{D}_2 + CH_2D—C\mathcal{D}_2 \rightarrow \begin{matrix} {}^2/_3 \\ {}^1/_3 \end{matrix} \left\{ \begin{matrix} C\mathcal{D}_2D + CH_2 = C\mathcal{D}_2 \\ C\mathcal{D}_2H + CHD = C\mathcal{D}_2 \end{matrix} \right\} \qquad (5, 2')$$

leads to the formation of methane, for which the extent of deuteration can be calculated from the extent of deuteration of methyl radicals ($\%\,D_{C\mathcal{D}_3}$) and $\%\,D$ — the composition of the heavy hydrogen passed through the discharge

$$(\%\ D_M)_{[D]\to 0} = {}^3/_4(\%\ D_{C_2D_6}) + {}^1/_4 \cdot {}^1/_3 \cdot (\%\ D). \qquad (6)$$

In our experiments a mixture of hydrogen and deuterium containing 96.5% of the latter was passed through the discharge tube, so that

$$\%\ D = 96.5\% \text{ and } D_{C_2D_6} \approx (0.965)^6 \cdot 100 \approx 90.$$

Substituting these values in Equation 6 we obtain

$$(\%\ D_M)_{[D]\to 0} = 75.5\%$$

So that according to the atomic exchange scheme the deuteration of methane formed in the system $(D + D_2) + C_2H_4$ at $[D] \to 0$ should not proceed to an extent of more than 33%, whereas according to the molecular exchange scheme it can attain 75.5%.

In experiments with isobutene and propene the extent of the deuteration of methane should differ from the values calculated by either scheme owing to the fact that it is determined by the probability of the saturation of the methyl radical by a D atom of the isobutyl or propyl radical, respectively. However, in all three cases the extent of the exchange of methyl radicals (i.e. $\%D_{CD_3}$) must be the same — 33%, according to the atomic exchange scheme and 90% according to the molecular exchange scheme.

2. A diagram of the apparatus used in these experiments is given in Fig. 1. Beyond the zone of the electrical discharge, alkene was admixed to the stream of partially dissociated deuterium. The mixture of gases together with reaction products was then passed through one of five traps 6-10 cooled with liquid nitrogen, these being connected in parallel and provided with taps. In each of these traps condensable products were frozen out; these products were formed by the action of deuterium atoms, the concentration of which was determined by the magnitude of the discharge current ($[D] \approx \sqrt{I}$ [6]).

The stream of gases that did not condense at the temperature of liquid nitrogen (methane + deuterium) then passed through one of the five traps 1-5, which were similar to those described above, but were filled with activated charcoal. The whole of the methane and much of the deuterium were in this way removed from the stream. The use of this system of traps enabled us to obtain five test samples of the reaction products in one experiment, so that the question of nonreproducibility of results from one experiment to another did not arise.

Before an experiment, the apparatus and traps were evacuated to a pressure of 10^{-6} mm, and degassing of the charcoal was effected by heating the quartz traps 1-5 with the flame of hand gas blowpipe. All the taps were then closed, and the tap a was turned into the position A in order to evacuate the discharge tube and the reaction vessel while bypassing the traps. A stream of hydrogen was then passed periodically through the discharge tube and the discharge was switched on at a current of 400-500 ma. This resulted in the heating of the electrodes, which facilitated complete removal of possible contamination from them. This degassing of the electrodes was carried out several times, the discharge being finally produced in deuterium. Before passage into the discharge tube, the deuterium was passed through a trap cooled with liquid nitrogen in order to remove vapors of grease and mercury.

After the establishment of the deuterium stream, the alkene (ethylene, propene, or isobutene) supply was turned on,* and the current in the discharge was maintained at a definite value, controlled by potential difference across the electrodes. After 2-3 minutes first taps 1 and 6 and then taps 1' and 6' were opened. Immediately afterwards, tap a was turned from the position A (evacuation of the tube) to position B (evacuation of traps). The stream of gases then passed through the trap 6, through the trap 1, and then through the tap a to the pumps.

* Deuterium and alkene were added at constant rate through the calibrated capillaries K_D and K_{RH} (Fig. 1).

Fig. 1. Diagram of apparatus for the study of reactions in the system $(D + D_2)$ + alkene: 1-10– traps with taps 1,1'–10,10'; 11– discharge tube; 12– reaction vessel with electric furnace 13; 14– mercury diffusion pump for pumping gases from traps into the flask 15; 16– McLeod gage; 17– LT- lamp manometer; 18– side tube for the freezing-out of gases; 19– manometer; 20– mercury diffusion pump with trap and fore-vacuum flask; 21– vacuum taps; 22– "rake" for the transference of gas samples to the mass spectrometer for analysis; K_D, K_H, and K_{RH}– calibrated capillaries for the delivery of gas from the respective flasks.

Reaction proceeded for two minutes, the condensable products being trapped in trap 6, and methane and deuterium (D_2 + HD + H_2) in trap 1. The tap 3 was then turned into position A, and tap 6 was closed. After 30 seconds taps 1 and 1' were closed and taps 2 and 7 were opened. The desirable current strength was established in the discharge and at the end of the third minute the operations described were repeated in traps 2 and 7, and so on.

The heavy hydrogen passing into the discharge tube in our experiments contained 96.5% deuterium. The current passed in the discharge was varied from 20 to 500 ma. The pressure of the gases in the stream was about 1 mm.

3. The separation of methane–deuterium mixtures adsorbed on charcoal was carried out by pumping off the deuterium with the diffusion pump 14 into the flask 15, from which it could be removed further with the aid of the pump 20. In order to follow the course of the pumping of deuterium into the flask 15, the LT-2 lamp manometer 17 was fused on and the variation of pressure was recorded with the autographic recorder EPP-09. The separation of deuterium was considered to be complete when, after a preliminary thawing of the charcoal trap and refreezing with liquid nitrogen,* there was a rise in pressure in the flask 15 (the tap 21 being open) in the next 10-15 minutes. The pure methane remaining in each trap was desorbed at room temperature and then transferred by adsorption on charcoal at –196° into one of the branches of the detachable "rake" 22. The rake with its samples of methane was transferred to the mass spectrometer, on which it was analyzed for isotopic composition.

5. The mass spectra of deuteromethanes were determined on an MS-4 apparatus at an emission current of 2 ma and an ionizing p.d. of 70 v. Before the measurements the tube was carefully degassed by long heating and

* The taps on the traps were of course closed during these operations.

evacuation. In some cases the tube was evacuated down to $8 \cdot 10^{-8}$ mm, and in others to $1 - 1.2 \cdot 10^{-7}$ mm. As a result, there was almost no "background" in the region of masses 12-21. The gas pressure during the measurements was about $3 \cdot 10^{-3}$ mm in the region of the source of ions and $2 \cdot 10^{-2}$ mm in the tube. The mass spectra were automatically recorded on the paper tape of the autographic recorder.

The relative amounts of the various deuteromethanes in the mixture and the average degree of deuteration of each sample were calculated on the assumption that the distributions of the corresponding peaks in the spectra of CH_4 and any of the CH_xD_{4-x} molecules were identical. The mass spectrum of CH_4 was determined for a sample obtained under conditions similar to those used in the formation of deuteromethanes, the discharge being passed through hydrogen instead of deuterium.

Discussion of Experimental Results

Table 1 gives experimental conditions and results for experiments carried out in the systems $(D + D_2) + C_2H_4$, $(D + D_2) + C_3H_6$, and $(D + D_2) + i\text{-}C_4H_8$. Curves, constructed from these data, showing the dependence of the degree of deuteration of methane on the strength of the discharge current (i.e. on $[D]^2$) are given in Fig. 2. As will be seen from the respective curves, 1, 2, and 3, the degree of deuteration of methane rises with increase in [D] in the ethylene experiments, but falls in the propene and isobutene experiments. The cause of this behavior in the relationship between $\%\ D_M$ and [D] will be considered below, and we shall now consider the values of the degree of deuteration of methane at $[D] \to 0$, as found by extrapolation of the curves 1, 2, and 3 to their intersection with the axis of ordinates. Extrapolation of Curve 1, which corresponds to the system $(D + D_2) + C_2H_4$, gives a value of 73.7 for $(\%\ D_M)\ [D] \to 0$.

TABLE 1

Degree of Deuteration of Methane formed in the System $(D + D_2) +$ + RH at Different Concentrations of D Atoms

System	Temperature (°C)	Current (ma)	Ratio $[D_2]:[RH]$	Degree of deuteration of methane ($\%\ D_M$)
$(D + D_2) + C_2H_4$ . . .	25	50	50 : 4	74.5
	25	100	50 : 4	75.0
	25	200	50 : 4	76.5
	25	300	50 : 4	78.0
	25	500	50 : 4	81.5
$(D + D_2) + C_3H_6$ . . .	25	25	50 : 4	78.1
	25	50	50 : 4	77.3
	25	125	50 : 4	74.6
$(D + D_2) + i\text{-}C_4H_8$ . .	25	25	50 : 4	89.5
	25	75	50 : 4	89.2
	25	200	50 : 4	88.9
	25	275	50 : 4	88.6

The experimentally observed degree of deuteration of methane is considerably higher than that calculated (33%) in accordance with the scheme of exchange between methyl radicals and D atoms, but it is in close accord with value of 75.5% calculated according to the molecular exchange scheme. We reach the same conclusion when we compare calculated and experimental values of the degree of deuteration of methane formed in experiments with propene and isobutene (Table 2).

Let us examine this question in greater detail. As we have pointed out above, if we assume a mechanism of the formation of methane by reactions of the type (5, 0-2), the extent of its deuteration can be determined by the equation

$$(\%\ D_M)_{[D] \to 0} = \tfrac{3}{4}\ (\%\ D_{C_xH_y}) + \tfrac{1}{4} \cdot \beta \cdot \%\ D,$$

in which $\%\ D_{C_xH_y} = (0.965)^3 \cdot 100 = 0.90$, and $\%\ D = 96.5$.

With the aid of the values of $(\%\ D_M)_{[D] \to 0}$ in Experiments 2 and 3 we may determine the probability β of the saturation of methyl radicals with D atoms. The relevant calculation gives $\beta_2 = 0.5$ in the experiment with propene and $\beta_3 = 1$ in the experiment with isobutene. This implies that the saturation of methyl radicals in these experiments proceeds by disproportionation with the respective radicals

Fig. 2 Curve for the degree of deuteration of methane formed in the system (D + D_2) + alkene as a function of the concentration of D atoms in the system: 1—(D + D_2) + C_2H_4; 2—(D + D_2) + + C_3H_6; 3—(D + D_2) + i-C_4H_8.

These results are in agreement with those of our previous investigation [4, 5], in which it was shown that in the addition of deuterium (or hydrogen) atoms to isobutene both tert-butyl and isobutyl radicals are formed and that isobutyl radicals enter the disproportionation reaction with transfer of the D (or H) atom at the tertiary carbon atom with greater ease than tert-butyl radicals. We must point out that in the calculation of the probability β we used the value of the extent of exchange of methyl radicals obtained in accordance with the molecular exchange scheme. Calculation in accordance with the atomic exchange scheme gives values of β of greater than unity (β_2 = 2.1 and β_3 = = 2.7) which is absurd. These results confirm the fact that we established previously, namely, that exchange with the free radicals is effected with the participation of deuterium molecules, not atoms.

We shall now examine the question of the degree of deuteration of methane as a function of the concentration of D atoms.

TABLE 2

Calculated and Experimental Values of the Degree of Deuteration of Methane formed in the System (D + D_2) + Alkene (% D = 96.5)

Experiment No.	System	Isotopic Composition of methane	$(\%D_M)_{[D]\to 0}$ according to the atomic exchange scheme	$(\%D_M)_{[D]\to 0}$ according to molecular exchange scheme	$(\%D_M)_{[D]\to 0}$ found by experiment
1	(D + D_2) + C_2H_4	$C\mathcal{D}_3$ ($^1/_3$D + $^2/_3$H)	32	75.5	73.7
2	(D + D_2) + C_3H_6	$C\mathcal{D}_3$ ($^1/_3$D + $^1/_3$H)	38	79.5	79.8
3	(D + D_2) + i-C_4H_8	$C\mathcal{D}_3$D	48	91.5	89.6

Reaction in the System (D + D_2) + C_2H_4

According to the reaction (5, 2°), in disproportionation between methyl and ethyl radicals, molecules of deuterated ethylene are formed as well as methane. With increase in the concentration of D atoms in the system, it becomes increasingly probable that the ethylene molecules will again react with D atoms with formation of ethyl radicals of, for example, the following isotopic composition:

$$1.\ CHD = C\mathcal{D}_2 + D \rightarrow CHD_2 - \dot{C}\mathcal{D}_2. \qquad (7)$$

$$2.\ CHD = C\mathcal{D}_2 + D \rightarrow \dot{C}HD - C\mathcal{D}_2D \xrightarrow[\text{exchange}]{D_2} \dot{C}\mathcal{D}_2 - C\mathcal{D}_2D.$$

It is quite to be expected that disproportionation between methyl radicals and such deuterated ethyl radicals will give more highly deuterated methane

$$\dot{C}\mathcal{D}_3 + CD_2H - \dot{C}\mathcal{D}_2 \rightarrow \begin{matrix} {}^2/_3 \\ {}^1/_3 \end{matrix} \begin{cases} C\mathcal{D}_3D + CHD = C\mathcal{D}_3 \\ C\mathcal{D}_3H + CD_2 = C\mathcal{D}_3 \end{cases} \qquad (8)$$

as in this case CD_3D molecules will be formed with a probability of 2/3, not 1/3 as in reaction (5, 2'). Finally, disproportionation with $CD_3D-\dot{C}D_2$ radicals must give CD_3D and CD_4 molecules exclusively.

Hence, the cause of the increase in the degree of deuteration of methane formed in the system $(D + D_2) + C_2H_6$ with increase in the concentration of D atoms is to be found in the increase in the number of deuterated ethyl radicals taking part in disproportionation with methyl radicals.

It will be clear that the number of deuterated ethyl radicals taking part in reaction (8) will be proportional to the square of the concentration of deuterium atoms, since their formation by reactions (5, 0) and (7) requires two D atoms. We have already pointed out that $[D] \approx \sqrt{I}$, so that the "supplementary" deuteration of methane must vary linearly with the strength of the discharge current. This is actually observed experimentally (Curve 1, Fig. 2).

Reactions in the Systems $(D + D_2) + i\text{-}C_4H_8$ and $(D + D_2) + C_3H_6$

We have already pointed out above that the high value of $(\%\ D_M)_{I\to 0}$ in the reaction with isobutene is due to disproportionation between methyl radicals CD_3 and the isobutyl radicals formed together tert-butyl radicals. The isobutene molecules formed by further reaction with D atoms again give radicals of two types. On the other hand, isobutyl radicals undergo atomic cracking more readily than tert-butyl radicals [4, 5]. As a result of these circumstances, with increase in the concentration of D atoms in the system the ratio of the amounts of tert-butyl and isobutyl radicals rises sharply. At the same time it becomes more probable that the reaction

$$1.\ \dot{C}D_3 + CH_3-\underset{\displaystyle CH_3}{\overset{|}{C}}D-\dot{C}H_2 \rightarrow CD_3D + \text{isobutene}$$

will meet competition from the reaction

$$2.\ \dot{C}D_3 + CH_3-\underset{\displaystyle CH_3}{\overset{|}{\dot{C}}}-CH_2D \rightarrow \begin{matrix} {}^1/_9\{ & CD_3D + i\text{-}C_4H_8 & \} \\ {}^8/_9\{ & CD_3H + i\text{-}C_4H_7D & \} \end{matrix} \qquad (9)$$

The latter process results in the formation of CD_3H molecules with a probability of 8/9 and of CD_3D molecules with a probability of only 1/9, whereas in the reaction (9, 1) only CD_3D molecules will be formed. This, in our opinion, is the cause of the fall in the degree of deuteration of methane formed in the system $(D + D_2) + i\text{-}C_4H_8$ with increase in the concentration of D atoms (Curve 3, Fig. 2). It should be noted that in the experiments with ethylene the fall in the degree of deuteration is linear with respect to I, i.e. depends on $[D]^2$. The fall in the degree of deuteration of methane is much steeper in the reaction with propene (Curve 2, Fig. 2), which may readily be explained when we consider that in this case with increase in the concentration of deuterium atoms the competition of two reactions occurs:

$$\begin{matrix} 1.\ \dot{C}D_3 + CH_3-CHD-\dot{C}H_2 \rightarrow & {}^1/_3\{ & CD_3D + \text{propene} & \} \\ & {}^2/_3\{ & CD_3H + \text{propene} & \} \\ 2.\ \dot{C}D_3 + CH_3-\dot{C}H-CH_2D \rightarrow & {}^1/_6\{ & CD_3D + C_3H_6 & \} \\ & {}^5/_6\{ & CD_3H + C_3H_5D & \} \end{matrix} \qquad (10)$$

It follows from the difference in the slopes of Curves 2 and 3 that in the propene experiment the contribution of reaction (10, 2) in the formation of methane is considerably greater than that of the analogous reaction (9, 2) in the isobutene experiment. In our opinion this must be attributed to the fact that in the disproportionation reaction with methyl radicals the primary hydrogen atoms (H or D) in isopropyl radicals can compete more readily with secondary H or D atoms in propyl radicals than primary and tertiary H or D atoms can in isobutyl

and tert-butyl radicals respectively. From this we may draw the very reasonable conclusion that the mobility of hydrogen atoms (H or D) attached to α-carbon atoms in radicals increases in the series:

SUMMARY

1. The present investigation, which differs from our previous investigations in that the mass-spectrometric method of analysis was used, provides quantitative data that confirm the correctness of the mechanism that we have proposed, according to which exchange occurs between free radicals and molecular deuterium. It is shown that deuterium atoms do not play an appreciable part in the process of exchange with free radicals.

2. Our previous conclusion - that in the addition of hydrogen atoms (H or D) to alkenes, radicals of both possible types are formed - is confirmed.

3. It is shown that the main reaction resulting in the formation of methane from methyl radicals at low temperature is one of disproportionation with larger radicals.

4. It is shown that, in disproportion reactions with other radicals, the mobility of the hydrogen atom (H or D) attached to the α-carbon of the radical increases as we move from a primary to a tertiary atom.

COKE FORMATION ON ALUMINOSILICATE CRACKING CATALYSTS

B. V. Klimenok, E. A. Andreev, and V. A. Gordeeva

Carbonaceous deposits formed on catalysts in high-temperature reactions are generally regarded as products of undesired side reactions that accompany the main reaction. For a long time the same view was held with respect to the "coke" - carbonaceous and resinous deposits - formed on aluminosilicate catalysts in the cracking of hydrocarbons. The investigations of Frost [1], Thomas [2], and others have shown that coke, though reducting the activity of an aluminosilicate catalyst, nevertheless plays an important, positive role in catalytic cracking, being a hydrogen donor that can bring about the saturation of unsaturated catalytic-cracking products.

The nature of coke is still obscure. Apart from the short paper by Thomas [2], no studies of the nature of coke have appeared in the literature. It must be pointed out that, even then, this single investigation by Thomas suffers from substantial methodological defects that lower the value of the experimental results. The main fault lies in the fact that reversibly adsorbed cracking products were not removed from the catalyst surface. In the combustion of the coke, these reversibly adsorbed hydrocarbons also underwent combustion. The determination of the composition of the coke was therefore not reliable. It is doubtful whether the empirical formula found for the coke ($CH_{1.31}$) represented its true composition; it should have been poorer in hydrogen. After extraction of soluble substances in benzene, the coke was found to be still richer in hydrogen ($CH_{1.42}$).

With the object of studying the nature of coke and the part it plays in the process of catalytic cracking, we carried out investigations in the following directions: 1) improvement of the method of determining the amount and composition of the coke; 2) determination of the relationship between the composition of the coke and the duration of cracking; and 3) investigation of the degree of unsaturation of the coke.

EXPERIMENTAL

Improvement of the Method of Determining the Amount and Composition of the Coke

Coke is now generally analyzed by combustion in air and absorption of carbon dioxide and moisture with suitable substances. Before the combustion the carbonized catalyst is treated in a stream of pure nitrogen for some time, this being supposed to remove all of the reversibly adsorbed hydrocarbons. Experiment shows, however, that blowing-out with nitrogen does not remove them completely. Thus, when hot carbonized catalyst is blown out with nitrogen for 0.5-1 hour and the system is then connected to an oil pump and evacuated through a trap cooled with liquid air, a certain amount of liquid hydrocarbons always collects in the trap. For example, in one experiment (No. 64), after 30 ml of carbonized catalyst had been blown out for 30 minutes with nitrogen, 0.02 g of liquid hydrocarbons was extracted from it by evacuation. It will be clear that the combustion of these adsorbed hydrocarbons together with the coke would yield incorrect results for the amount and composition of the coke. The error resulting from the combustion of 0.02 g of liquid hydrocarbons can be estimated roughly. In the same experiment, after the blowing and evacuation the amount and composition of the coke was determined:

Amount of coke ..... 30.9 mg
Composition of coke ..... $CH_{0.88}$

Hence, if the catalyst had not been evacuated, the amount of coke determined by combustion would have been 30.9 + 20 = 50.9 mg, i.e. 65% greater than the actual value; the composition would have been expressed by the formula $CH_{1.97}$ (it is assumed that the liquid hydrocarbons removed by the pump were olefins C_nH_{2n}). This was confirmed also by direct comparison of determinations on the coke with and without the evacuation (Table 1). The experiments were carried out under identical conditions.

TABLE 1

Experiment 64	Amount of coke (mg)	Composition of coke
With evacuation	30.9	$CH_{0.48}$
Without evacuation	51.1	$CH_{1.12}$

TABLE 2

Carbon in the form					Total carbon (mg)
CO_2		CO			
(mg)	(%)	(mg)	(%)		
5.1	52	4.6	48		9.7
22	84.6	4.0	15.4		26
42	75	14	25		56
92	84.3	17	15.7		109

It is clear from these results that the determination of the actual composition and amount of the coke demands a more careful removal of reversibly adsorbed hydrocarbons than that which can be achieved by the usual blowing with nitrogen. Evacuation with an oil pump (0.01 mm) at 350-400° removes practically the whole of the reversibly adsorbed hydrocarbons in 10-15 minutes.

It is of no less importance for the determination of the actual composition of the coke to take account of the carbon that is oxidized during the regeneration into CO and is therefore not trapped by the CO_2 absorber. Experiment shows that the percentage content of CO varies greatly according to the experimental conditions. Thus, in Experiment 66 composition and quantity determinations were carried out on equal volumes of catalyst carbonized to different extents. The carbonized catalysts were subjected to evacuation for 20 minutes. The coke was oxidized with air at 550°, the carbon dioxide being absorbed with Ascarite, and the carbon monoxide collected in the exit gases and determined by absorption with ammoniacal cuprous chloride. Table 2 gives the results of the carbon estimations on the coke.

It will be seen from Table 2 that the content of carbon present as CO varies over a wide range (15-48%). An appreciably greater proportion of carbon leaves in the form of CO in the regeneration of weakly carbonized catalysts. In all the succeeding experiments on the nature of the coke, the procedure that we had shown to be essential - evacuation of the catalyst before the combustion of the coke and making allowance for CO in the analysis of the combustion products - was adopted.

Determination of the Relationship between the Composition of the Coke and the Duration of Cracking

The effect of the duration of cracking on the composition of the coke was studied for the case of the cracking of hexane over spherical-grain aluminosilicate catalyst. The duration of cracking was varied from 1.5 to 180 minutes; the temperature of cracking was 520°; the space velocity for the hexane was kept constant at 0.27 $hour^{-1}$ in all experiments; and the amount of catalyst was 30 ml. After the cracking the catalyst was evacuated with an oil pump for 20 minutes at 400°. The analysis of the coke was carried out by the method described above, account being taken of the carbon monoxide formed. Four experiments of duration 1.5, 15, 60, and 180 minutes were carried out. The results of the analysis of the combustion products are given in Table 3.

The composition and the amount of the coke are shown as functions of the duration of cracking in Fig. 1. The number of hydrogen atoms per carbon atom in the coke and the amount of coke (mg) are plotted as ordinates, and the duration of cracking (minutes) as abscissae. It will be seen from Fig. 1 that, with increase in the duration of cracking, the coke becomes poorer in hydrogen and this impoverishment

TABLE 3

Duration of cracking (minutes)	Weight of absorbed H_2O (mg)	Weight of absorbed CO_2 (mg)	Volume CO collected (ml at STP)
1.5	11.7	18.3	8.7
15	19.2	80.1	7.5
60	24.9	154.7	26
180	39.3	354.7	32

TABLE 4

Duration of cracking (minutes)	Weight of hydrogen in coke (mg)	Weight of carbon in coke (mg)	Weight of coke (mg)	Composition of coke
1.5	1.3	9.7	11.0	$CH_{1.61}$
15	2.13	26	28.1	$CH_{0.98}$
60	2.77	56	58.8	$CH_{0.59}$
180	4.37	109	113.4	$CH_{0.48}$

Fig. 1.

proceeds particularly rapidly at the beginning of the cracking. In the course of the first hour the atomic ratio of hydrogen to carbon is reduced by a factor of almost three (from 1.6 to 0.6), whereas in the course of the next two hours it is reduced by a factor of only 1.25 (from 0.6 to 0.48).

Investigation of the Degree of Unsaturation of the Coke

Experiments on the cracking of hexane and isooctane with participation of radioactive ethane, ethylene, and propene labeled with the carbon isotope C^{14} indicates that the coke is formed mainly from olefins [3]. It is possible that the formation of coke on a catalyst begins with the polymerization of olefins and the formation of polyolefins as a result of the partial decomposition of the polymers[4]. In this case the coke, particularly when "young", should possess some unsaturation.

With the object of determining the degree of unsaturation of the coke, a method was developed for the determination of its iodine value (grams of iodine required to saturate 100 g of coke). The carbonized catalyst (10-20 g) was ground in an iron mortar to 0.5-0.3 mm grains. It was found to be best to sieve out the larger and the finer particles. The ground catalyst was placed in a flask, and a titrated iodine solution was added until a thin slurry was obtained. The flask was closed with a glass stopper and placed in the dark for ten minutes. Distilled water (200 ml) was then added, and iodine was titrated as usual with thiosulfate, it being preferable to add starch before the end of the titration. As the suspension was dark in color, some experience is necessary in order to detect the disappearance of the blue color of the starch. The blue color is most readily seen in the upper layers of the suspension after it has been allowed to stand for 10-20 seconds. Also, at the end point the suspension loses its relative stability and begins to precipitate appreciably more rapidly after being shaken. It is necessary simultaneously to carry out a similar titration of the same amount of fresh catalyst (control experiment) in order to take account of adsorption of iodine by the aluminosilicate. The amount of iodine required is generally only a small fraction of the amount absorbed by the coke.

In order to calculate the iodine value of the coke it is necessary to determine the coke content (% by weight) of the catalyst on another sample of the same portion of carbonized catalyst. The iodine value was calculated from the formula:

$$I = \frac{10{,}000\,[a \cdot T_{I_2} - (b_1 - b_2)T_{Na_2S_2O_3}]}{cp},$$

Fig. 2

TABLE 5

Duration of cracking (minutes)	Coke content of catalyst (% by weight)	Weight of coke (g)	Iodine value of coke
14	0.106	0.0235	110
60	0.189	0.0425	62
162	0.516	0.117	38
360	0.781	0.169	34.5

in which a is the volume of iodine solution (ml), b_0 is the volume of thiosulfate solution (ml) required in the control experiment, b_1 is the volume of thiosulfate solution (ml) required in the titration of the coke, c is the weight of catalyst (g), p is the coke content of the catalyst (% by weight), T_{I_2} is the titre of the alcoholic iodine solution, and $T_{Na_2S_2O_3}$ is the iodine titre of the thiosulfate solution.

It was found that the coke was indeed more or less unsaturated. In order to determine the dependence of the degree of unsaturation of the coke on its "age", several samples of catalysts were prepared with different degrees of carbonization. The carbonization of the catalysts was carried out by cracking hexane at 520°, the hexane being passed in at a space velocity of 0.275. Four portions of catalyst, each 30 ml, were carbonized for 14, 60, 162, and 360 minutes. The results of the determinations of the amount of coke and its iodine value are given in Table 5.

The dependence of the iodine value of the coke and the degree of carbonization of the catalyst on the duration of cracking is shown in Fig. 2. It can be seen from Fig. 2 and Table 5 that "young" coke has high iodine values of 100 or more, indicating that it has considerable unsaturation. With increase in the duration of catalytic cracking the iodine value of the coke diminishes. The saturation of the coke is particularly rapid in the early period of the catalytic cracking. In the first hour the iodine value of the coke falls from 110 to 60, i.e. by almost 50%. The fall then becomes less marked, and after three hours the iodine value of the coke becomes stabilized at a level of 30-35. Even "old" coke, therefore, has a certain degree of unsaturation, probably attributable to the later deposits. Simultaneously, as can be seen from Fig. 2, the amount of coke increases continuously.

Calculation shows that in a coke of iodine value 110 there is one double bond for about 16 carbon atoms, and in a coke of iodine value 34.5 — one double bond for 53 carbon atoms. Comparison of the iodine values (Table 5) with the compositions (Table 4) of the cokes shows that in catalytic cracking an aliphatic coke ($CH_{1.6}$; I = 110) is formed at first, and this is then gradually converted by condensation into an aromatic coke ($CH_{0.4}$, I = 30).

In order to resolve the question of whether the variation in the degree of unsaturation of the coke with duration of cracking is essentially associated with the cracking process itself, the following experiment was carried out.

The cracking of hexane was carried out over 60 ml of aluminosilicate catalyst for 10 minutes. The cracking temperature was 520°, and the hexane was passed in at a space velocity of 0.275 hours^{-1}. After the cracking the catalyst was evacuated for 20 minutes, removed from the reactor, and halved. The first half was immediately analyzed for coke content and iodine value, and the second half was returned to the reactor and treated with a stream of pure nitrogen at 520° for three hours. The second half of the carbonized catalyst was then analyzed for iodine value and coke content. The results of the determinations are given in Table 6.

The iodine values and coke contents of the two portions of catalyst are the same within the errors of measurement. It may therefore be concluded that heating of the carbonized catalyst for three hours in an inert atmosphere does not affect the iodine value and that the reduction in the degree of unsaturation of the coke under conditions of catalytic cracking, as also the change in the composition of the coke, is

TABLE 6

Catalyst	Coke content of catalyst (% by wt.)	Iodine value of coke
First half	0.092	130.4
Second half	0.105	142
Mean	0.098	136.2

TABLE 7

Portion No.	Space velocity of hexane ($hour^{-1}$)	Coke content of catalyst (% by weight)	Iodine value of coke
1	0.275	0.23	38
2	1.11	0.124	34
3	1.74	0.098	30
		Mean	34

TABLE 8

Duration of cracking (minutes)	Temperature (°C)	Coke content of catalyst (% by weight)	Iodine value of coke
60	460	0.23	38
60	520	0.19	60

associated essentially with the reactions occurring in catalytic cracking over aluminosilicates. The aging of the coke, i.e. the cyclization and condensation of the hydrocarbons of the coke, occurs only to the extent that redistribution of hydrogen occurs in the catalytic cracking.

The effect of the space velocity or contact time on the iodine value of the coke was also studied. Three 30-ml portions of catalyst were carbonized at different space velocities of hexane – 0.273, 1.11, and 1.74. Hexane cracking was carried out at 460° for one hour. The results of determinations of iodine values and coke contents are given in Table 7.

The results in Table 7 show that the degree of unsaturation of the coke does not greatly depend on the space velocity at which the starting material is passed in. For an increase in the space velocity from 0.275 to 1.74, i.e. by a factor of more than six, the iodine value of the coke fell by only 11%. Such a change is within the limits of the errors of measurement of iodine values for coke.

The effect of temperature on the rate of saturation of the coke can be seen from Table 8.

Both experiments were carried out at the same space velocity of hexane, 0.275 $hour^{-1}$. The amount of catalyst was 30 ml.

It will be seen from Fig. 8 that rise in the temperature of catalytic cracking is accompanied by a rise also in the iodine value of the coke, i.e. the rate of saturation of the coke falls. This accords with the known fact that the content of unsaturated hydrocarbons in cracking products increases with rise in the cracking temperature.

SUMMARY

1. In catalytic cracking the elementary composition of the coke formed changes in the direction of impoverishment in hydrogen as the process proceeds. At the beginning of cracking the composition of the coke can be expressed approximately by the formula $CH_{1.6}$, and when the impoverishment in hydrogen has reached its limit it is expressed by the formula $CH_{0.5}$.

2. The coke always has a definite degree of unsaturation. The earliest coke has an iodine value of 150. Coke saturated to the limit probably has an iodine value of zero. The saturation of the coke is organically associated with the redistribution of hydrogen in the process of catalytic cracking.

3. Change in the space velocity at which the starting material is passed in has almost no effect on the rate of saturation of the coke.

4. With rise of temperature, the rate of saturation of coke in the catalytic cracking process diminishes.

5. A comparative examination of the compositions and iodine values of the cokes shows that in the course of the cracking process the nature of the coke changes. As, in the course of the cracking, hydrogen is given up for the saturation of unsaturated cracking products, so the coke becomes converted into a saturated condensed-aromatic coke.

DETERMINATION OF π-ELECTRON DENSITY AND INTERATOMIC DISTANCES

COMMUNICATION 3. CONFIRMATION OF THE HYPOTHESIS

G. V. Bykov

Four years ago I published three papers [1-3]* in which it was suggested, first, that the general π-electron cloud (equivalent to n electrons) of a molecule consists of π-electron bond charges such that each separate charge A may have a fractional value when expressed in electronic units,

$$\Sigma A = n; \qquad (1)$$

and second, that all bonds formed by atoms that are π-electron donors may posses a certain π-electron charge. Morcover, an equation was proposed which expressed a linear relationship between π-electron charge and bond length, and numerous calculations were made with the aid of this equation.

In the last four years several papers have appeared that are closely allied in subject matter. It was considered desirable to compare the basic theses of these authors and the results of their calculations with mine and to take a brief glance at the future prospects of this line of work.

I

The concept of the π-electron charge of bonds must be distinguished from the concepts of percentage double-bond character and of fractional order of bonds; the latter are theoretical concepts that have no clear physical meaning and they are unable to express the additivity of π-electron charges of bonds. However, to a certain extent they can be regarded as approximations to the concept of π-electron charge. At least, if we avoid the concept of the fractional order of a bond in the form proposed and developed by Coulson [4-6], we can make the transition to the concept of π-electron charges. This transition was made by McWeeny [7], whose investigation, which was of a preliminary nature, was published almost at the same time as our second paper [2]. McWeeny states that in many cases it is preferable to divide the general π-electron charge of the molecule into localized regions, but although this procedure has been "tacitly assumed in certain cases (diatomic molecules), its generality and applicability has apparently not been determined". The total π-electron charge can be distributed between the atoms and bonds – the emphasis is McWeeny's – in such a way that the sum of the individual charges is equal to the total number of π-electrons. McWeeny points out that, unlike bond orders and free valencies, localized charges give an "analytical picture", which he illustrates for the case of naphthalene (see figure). McWeeny points out also the close relationship that must exist between the properties of a bond and its π-electron charge. We can agree with McWeeny's views in the main, but must take exception to his treatment in two respects: working by analogy to Coulson's method, he distributes π-electron charges not only among the bonds, but also among the atoms, and he does not indicate the possibility of a partial distribution of the π-electron charges in C–H bonds.

* We take this opportunity of pointing out some misprints: in [1], p. 393 on the tenth line from the bottom, read δ_{CH_3-C} instead of Δ_{CH_3-C}; in [2], p. 824 on the 27th line from the top, read $CH_3-C^{+\frac{1}{3}}_{-\frac{1}{3}}-CH$ instead of $CH_3-C^{-\frac{1}{3}}_{+\frac{1}{3}}-CH$; in [3], p. 368 on the 30th line from the top, read $\underline{1}_{CO}$ instead of $\underline{1}_{CO_2}$, and p. 371 on the 22nd and 23rd lines from the top, read CO instead of CO^2.

Distribution of the π-electron charges in naphthalene according to McWeeny.

TABLE 1

Distribution of π-Electron Charges in Naphthalene (for lettering of bonds see figure)

Bond	According to the data of			According to Equation 4
	Scherr [8]	Platt [9]	Bagdasaryan [10]	
A	1.078	1.04	1.005	1.19 (1.395) *
B	0.705	0.80	0.825	0.79 (1.425)
C	0.634	0.58	0.53	1.00 (1.393) **
D	0.937	0.98	0.955	0.93 (1.404)

* The interatomic distances are given in parentheses.

** The length of the bond C is not in accord with calculations by the molecular-orbital method (l_{CC}=1.424) and with the lengths of similar bonds in other condensed aromatic compounds; for example, the length of the analogous bond in anthracene is l_{CC}=1.438 and its π-electron charge, according to Equation 4, is A_{CC}= 0.71. To a lesser degree these remarks apply also to the bond A.

On the basis of a free-electron model, Scherr [8] has made calculations for a large group of aromatic hydrocarbons, and also for ethylene, butadiene, and 3-methylene-1, 4-pentadiene; they give values of π-electron charges only for C–C bonds. Unlike McWeeny, Scherr is inclined to identify π-electron charges ("densities") of bonds and the order of a "mobile" (π-electron) bond as understood by Coulson. As will be seen from the discussion above, there is no adequate foundation for this view. Platt [9] constructed a mechanical model for the determination of π-electron charges in aromatic molecules; his results are close to those of Scherr. By applying the quantum-statistical treatment of an electron gas to molecules containing conjugated bonds, Bagdasaryan [10] calculated the π-electron charges ("electron densities") of bonds in a series of hydrocarbons, but, like Scherr, he did not take the π-electron charges of C–H bonds into account.

Table 1 shows the distribution of π-electron charges in naphthalene according to the data of Scherr, Platt, and Bagdasaryan and also our value calculated from Equation 4 (see below) on the basis of Robertson's values for the interatomic distances [11].

In outlining a program of future work in my previous paper [3], I referred to the application of these methods and of the conclusions reached as the result of the calculation of π-electron charges to the study of the σ-electron distribution. However, before I communicated my results,* Sandorfy and Daudel [12] showed the possibility, at least in principle, of calculating σ-electron bond charges by the method of molecular orbitals. According to their calculations, the minimum value of the σ-electron charge of a C–C bond is A^{CC}=1.498 electrons.

It will be seen from these examples that problems relating to the electron charges of bonds are already receiving attention from theoretical chemists, who, unlike me, are approaching the solution of the problems from the point of view of quantum mechanics.

* I made this communication only in June 1955 at the All-Union Conference on Kinetics, Catalysis, and Reactivity in Moscow.

II

There is a large group of bonds in which only one of the two atoms forming the bond is a π-electron donor. It includes the bonds: C–H in acetylene, C–CH_3 in propene, C–Cl in phosgene, C–O in phenol, and C–N in aniline. In the last three compounds chemists assume the existence of a weak π-bond resulting from interaction between the π-electrons of carbon and free electron pairs of the valency shell of the chlorine, oxygen, and tervalent nitrogen atoms. It is from this point of view that explanations are now advanced for the shortening (as compared with a σ-bond) of , for example, the C–Cl bond in aromatic compounds [13] and in phosgene [14].

Such concepts have not been extended to C–C and C–H bonds owing to the absence of free electrons in the valency shells of hydrogen and σ-quadrivalent carbon. However, I have shown [1, 2] that these bonds also must have a certain π-electron charge.* Either indirectly or directly this view is shared by certain other authors. When Shigorin [15] writes that the π-electron of the atom C" in propylene $C'H_2{-}C''H{-}C'''H_3$ moves not only in the field of the atom C', but also in the field of the atom C"', this means that a π-electron-density distribution is created such that a part of it is associated with the bond C"–C"'. At the same time we cannot agree with Shigorin's assertion [16] that when a hydrogen of the methyl group of propene is replaced by halogen there will no longer be any π-electron interaction between the atoms C" and C"'**. A displacement of π-electron density in the C–CH_3 bond of propyne is assumed by B. and A. Pullman, who speak even of the symmetry of the π-electron cloud with respect to this bond [17].

As regards the C–H bond, Myers and Gwinn [18] in their review of the radiospectroscopy of gases indicate some experimental grounds for the view that the C–D bond in deuterochloroacetylene has π-electron character and that the similar shortening of the C–H bond is in accord with its π-electron character. Indirect proof of the distribution of π-electron charges in C–H bonds is provided also by Scherr's calculations, according to which the π-electron charge of the C–C bond of ethylene has the value A_{CC}=1.333 electrons. Where then in ethylene is the remaining 0.667 of a π-electron to be found, and why should not the remaining π-electron cloud in such compounds be oriented along C–H bonds?

We see therefore that more and more arguments are appearing in favor of the view that the π-electron cloud of an atom donor of π-electrons is distributed over all the bonds that it forms.

III

It is extremely probable that the value of the electronic charge of a bond mainly determines the properties of the bond. However, the form of the functional relationship must be determined for each property separately. On the basis of a comparative study of the experimental data, the author [2] concluded that there is a linear relationship between the length of a bond and its π-electron charge:

$$l = L - \Delta A, \qquad (2)$$

in which l is the bond length, L is the length of the standard single bond, A is the π-electron charge of the bond, Δ is the specific contraction (the shortening when A is one π-electron). L and Δ depend on the type of bond. Thus, for the C–C bond Equation 2 has the form:

* Thus, as a rule all bonds for which it is assumed that the percentage double-bond character $p > 0$ or the bond order $R > 1.00$ have a π-electron charge $A > 0$, but the converse is not necessarily true.

** There are other important theses in Shigorin's theoretical treatment, and, in the present author's opinion, whether one agrees with them or not, they should be given very serious consideration. If we consider only the main points, then in my view Shigorin's criticism of the concepts of the electron "doublet" and of "multiple" bonds are correct and timely, but one of his main theses– the hypothesis of the π-like electron– is, to say the least, superfluous: all the facts in the explanation of which it is applied can be explained equally satisfactorily by the character of the distribution of σ- and π-electron density. Another defect of Shigorin's theoretical scheme is its markedly qualitative character, whereas in operating with the concept of the magnitude of the π-electron charge of a bond, one may readily turn to a quantitative treatment of the questions examined by Shigorin.

$$l_{CC} = 1.542 - 0.149\, A_{CC}. \quad (3)$$

so that

$$A_{CC} = \frac{1.542 - l_{CC}}{0.149}. \quad (4)$$

The analogous formula for the C–N bond is:

$$A_{CN} = \frac{1.47 - l_{CN}}{0.1}. \quad (5)$$

Equation 4 was applied in the calculation of the π-electron charges of C–C bonds in various hydrocarbons for the first time. As will be seen from Table 2, the results are in good agreement with the later results of Scherr, Platt, and Bagdasaryan.

TABLE 2

Bond	According to the results of			
	Bykov [2]	Scherr [8]	Platt [9]	Bagdasaryan [10]
C–C in ethylene	1.42	1.333	—	—
C–C (2-3) in butadiene	0.55	0.800 (0.70)*	—	0.65 (0.55)*
C–C (ar-alk) in styrene	—	0.654 (0.60)*	—	0.74 (0.69)*
C–C (ar-alk) in stilbene	0.65	0.682 (0.63)*	0.74	—
C–C (1-1') in biphenyl	0.42	0.515	—	0.73

* In their calculations the authors assume that the π-electron charges associated with C–H bonds are zero, whereas according to my calculations [1] $A_{CH} = 0.1$ electron for the 2- and 3-C–H bonds of butadiene. The calculated values given in the original papers should therefore be reduced by 0.1 approximately for butadiene and by 0.05 approximately for styrene and stilbene.

For the relationship between the calculated values of the π-electron charges ("densities") and the experimentally determined interatomic distances Scherr proposes the following linear equation:

$$r - s\,(A) = 1.665 - 0.1398\,[1 + b\,(rs)], \quad (6)$$

in which $r - s\,(A)$ is the length of the C_r——C_s in angstrom – in our notation l_{CC} – and $b(rs)$ is the π-electron charge ("density") of the same bond – in our notation A_{CC}. Changing the notation and making a suitable transformation, we obtain:

$$l_{CC} = 1.525 - 0.1398\, A_{CC}. \quad (6a)$$

The similarity between Equations 3 and 6a is obvious, but there is a difference between them that is not in favor of Equation 6a, for at $A_{CC} = 0$ the latter equation gives a value of 1.525 A for the length of a single C–C bond, which is not in accord with fact: for diamond values of 1.542 and 1.544 have been found for l_{CC}; in ethane it is 1.535.

For the determination of π-electron charges in polyenes, Scherr proposes the empirical equation:

$$b(rs)\,[=A_{CC}] = 1 - \frac{(-1)^r}{(n+1)\sin\left\{\pi\left(r+\frac{1}{2}\right)\Big/ n+1\right\}}, \qquad (7)$$

in which r is the ordinal number in the chain for the first atom forming the bond and n is the total number of carbon atoms in the polyene. The formula expresses both the alternating effect and the gradual leveling out of the bonds with the lengthening of the chain, but it again does not take the π-electron charges of the C–H bonds into consideration.

Calculations of interatomic distances and π-electron charges of bonds with the aid of Equations 1 and 2 can, as I showed in previous papers [2, 3], be used for the correction of experimental data. In this connection great importance must not, of course, be attached to inferences made regarding the doubtfulness of certain experimental results, such as were made, for example, with respect to the lengths of the C–C and C–O bonds in acetone •, for it is sufficient to make comparisons with homologous and analogous compounds in order to arrive at the same conclusions. Inferences that cannot be made by any other means are of much greater interest. For example, I cast doubt on the experimental data for interatomic distances in allene [2]. It has been found [20] that the shortening of the C–C bond in allene is indeed greater than was supposed: the new value is $l_{CC} = 1.309$, whereas the old was $l_{CC} = 1.330$.

The same calculations can be also of theoretical interest. In the paper [3] I directed attention to the fact that the reduction in the π-electron charge of the C–O bond that is attributable to the participation of the oxygen in a hydrogen bridge gives reason to suppose that the hydrogen bond has a π-electron character. Shortly afterwards, a number of new arguments in favor of this supposition were advanced by Shigorin [12]. Another example: in the compound $(CH_3SO_2)_2CCNCH_3$ Wheatley [22] found the following interatomic distances: $>C\overset{1.542}{\text{———}}C\overset{1.154}{\text{———}}N\overset{1.424}{\text{———}}CH_3$; he concluded that in such compounds interatomic distances do not provide a satisfactory criterion for the assessment of bond order, since it would be necessary to assume the "quinquevalence" of the central carbon atom. Incidently, there is no anomaly here, as will be seen from a calculation of the π-electron charges of the bonds by Equations 4 and 5: $>C\overset{1.94}{\text{———}}C\overset{2.14}{\text{———}}N\overset{0.44}{\text{———}}CH_3$.

To the first approximation, therefore, Equation 2 expresses the relationship between the π-electron charges of the bonds and their lengths, and moreover, the good compatability of the results of calculations by this equation for the electron distribution in hydrocarbons, halogen-, oxygen-, and nitrogen-containing organic compounds, and certain inorganic nitrogen compounds [2, 3] provides weighty arguments in favor of the correctness of the views advanced in Sections I and II.

IV

What changes will be necessary if the above views, which have received confirmation from different directions, become accepted in chemistry? The principle according to which the covalent bond is formed by an integral, generally even, number of electrons, while remaining true to the first approximation, will have to give way to another system of postulates that are more closely in accord with actuality:

1. Covalent bonds vary with respect to the values of their σ- and π-electron charges.

2. The main characteristic of the covalent bond is the value of its σ- and π-electron charge, which is the main factor determining its properties.

3. The mutual effects of atoms are manifested by a certain distribution of σ- and π-electron charges in the bonds, which is the main factor determining the reactivity of the molecule.

4. For the calculation of the distribution of σ- and π-electron charges among bonds — and therefore for the establishment of the relationship between the physical and chemical properties of molecules — from the results of physical methods of investigation, it is possible to find methods of calculation that are cruder than quantum-mechanical methods, but are mathematically simple and universal in application.

• See the partial correction of these results in the paper of Allen et al. [19].

The acceptance of these views will result in substantial reconstruction of the modern electronic theory of molecular structure and reactivity and in re-examination of many of its underlying principles. The importance of this new line of thought must not be underestimated. The examples that we have given show conclusively that it has already begun to assert itself in work representing different lines of approach and carried out in different countries. The number of such examples could probably be increased *. Unfortunately, the individual investigators who are following this new path and are arriving at the same conclusions and even at identical numerical results are not yet coordinating their work together, and authors of reviews on molecular structure and the chemical bond for the most part either do not mention such investigations at all, or do not grasp the main significance of them. Sometimes it must be supposed that this work is deliberately ignored. However, the history of chemistry shows that no new line of thought has yet been welcomed with open arms by its contemporaries.

SUMMARY

1. Covalent bonds in molecules are formed by σ- and π-electron charges, which are not in general equal to a whole number of electrons.

2. All bonds attached to atom donors of π-electrons have π-electron charges.

3. To the first approximation, a linear relationship can be assumed between π-electron charge and bond length.

4. A new and very promising line of work is being developed in the theory of the electronic structure of molecules.

ORGANOPHOSPHORUS ETHYLENIMINE DERIVATIVES

COMMUNICATION 1. REACTION OF ETHYLENIMINE WITH DIALKYL PHOSPHOROCHLORIDATES

N. P. Grechkin

Organophosphorus ethylenimine derivatives have not yet been investigated systematically, and in the chemical literature there are only sporadic references (almost entirely in patents) to individual compounds [1-8]. It is however quite evident that organophosphorus ethylenimine derivatives are of great interest, both from the point of view of the development of methods of synthesizing organophosphorus compounds and from the point of view of their practical application (which is referred to in a comparatively large number of patents) and of the study of their biological activity.

By means of the method suggested by Bestian [1], which consists in the treatment an organophosphorus acid halide with ethylenimine in presence of triethylamine in benzene.

we prepared a series of dialkyl ethylenephosphoramidates [dialkyl P-1-aziridinylphosphonates] of general formula , in which R is an aliphatic radical containing 1-5 carbon atoms. By an analogous reaction we prepared also diethyl ethylenephosphoramidite:

The properties of the compounds obtained are given in Table 1. By making use of the reactivity of the ethylenimine ring, we succeeded in effecting some transformations of the ethylenephosphoramidic esters. When diethyl ethylenephosphoramidate was heated with a large excess of diethylamine in presence of ammonium chloride, the ethylenimine ring was opened with formation of diethyl 2-diethylaminoethylphosphoramidate. An analogous reaction [9] has been studied previously, 2-ethylaziridine being treated with an amine, e.g. morpholine, or ammonia.

Addition of ethyl bromide to this last compound yielded the ethobromide of diethyl 2-diethylaminoethylphosphoramidate as a readily crystallizing substance:

TABLE 1

Dialkyl Ethylenephosphoramidates and Diethyl Ethylenephosphoramidite

No.	Formula of substance	B.p. in °C (p in mm)	d_4^{20}	n_D^{20}	MR found	MR calculated	Phosphorus content (%) found	Phosphorus content (%) calculated	Yield (%)
1		99.5—100 (10)	1.2212	1.4375	32.42	32.67	20.62; 20.30	20.53	73.5
2		108.5 (9.5)	1.1148	1.4362	42.00	41.91	17.45; 17.57	17.31	82
3		127—128 (10)	1.0584	1.4382	51.36	51.15	14.97; 14.88	14.97	76
4		112—113 (12)	1.0439	1.4310	51.33	51.15	15.03; 15.09	14.97	74
5		146—147 (11)	1.0260	1.4407	60.45	60.38	13.39; 13.45	13.19	87.5*
6		135.5—136 (10.5)	1.0174	1.4367	60.48	60.38	13.16; 13.20	13.19	83*
7		155.5—156.5 (10.5)	1.0004	1.4415	69.49	69.67	11.90; 11.85	11.79	81*
8		57.5—58.5 (10)	1.0070	1.4458	43.15	43.13	18.95; 19.01	19.02	63.5

* An excess (about 10%) of triethylamine was taken.

An analogous reaction occurred when diethyl ethylenephosphoramidate was heated with benzenethiol: the ethylenimine ring was opened [10] with formation of diethyl 2-phenylthioethylphosphoramidate:

It must be pointed out that the ethylenimine (aziridine) ring substituted at the nitrogen by the dialkoxyphosphinyl group loses much of its reactivity: thus we were unable to open the ring of the ethylenephosphoramidic esters with phenol, whereas such a reaction has been described for other aziridines [11]. We were equally unsuccessful in our attempts to synthesize P-3-oxazolidinylphosphonic esters by reaction of ethylenephosphoramidic [P-1-aziridinylphosphonic] esters with aldehydes and ketones, although analogous compounds are readily obtained from ethylenimine even under mild conditions [12]. The behavior of ethylenephosphoramidic esters toward some other reagents (alkyl halides, acid halides, and others) was studied.

When dialkyl phosphorochloridates react with ethylenimine in absence of a base, the cyclic amide formed is broken down by hydrogen chloride with formation of dialkyl 2-chloroethylphosphoramidate:

In all, seven of these 2-chloroethylamides were prepared, R being an aliphatic radical having 1-5 carbon atoms. The constants of the compounds obtained are given in Table 2.

An attempt to synthesize diethyl 2-chloroethylphosphoramidite from diethyl phosphorochloridite and ethylenimine was not successful.

EXPERIMENTAL

1. Synthesis of Dialkyl Ethylenephosphoramidates. All of these compounds were prepared under analogous conditions. A solution of 31.4 g (0.157 mole) of dipropyl phosphorochloridate in 50 ml of dry benzene was added dropwise to a solution of 6.75 g (0.157 mole) of ethylenimine and 15.8 g (0.157 mole) of triethylamine in benzene over a period of 40 minutes at a temperature of from − 5° to + 5°. When the whole of the phosphorochloridate had been aded, the cooling bath was removed, and the mixture was stirred for 1.5-2 hours at room temperature. The reaction mixture was then heated for one hour at 40-50°. During the whole of these processes, the reactants were stirred together vigorously by means of a nichrome wire stirrer. The mixture was cooled to room temperature, and the triethylamine hydrochloride was then filtered off, washed twice with dry benzene, dried, and weighed; the yield was 20 g (94%). Benzene was distilled from the filtrate under reduced pressure. Two fractionations of the residue from an Arbuzov flask gave pure Substance 3 (Table 1) in 76% yield.

2. Reaction of Diethyl Ethylenephosphoramidate with Diethylamine. A mixture of 5.3 g of diethyl ethylenephosphoramidate, 21.5 g of diethylamine, and about 0.1 g of ammonium chloride was heated in a sealed tube at 80-85° for 28.5 hours. The excess of amine was distilled off under reduced pressure. Two fractiona-

6	$(i\text{-}C_4H_9O)_2PNH-CH_2-CH_2Cl$ ‖ O	136.5—138 (1.7)	1.0761	1.4458	67.25	67.45	11.71; 11.48	11.42	62
7	$(i\text{-}C_5H_{11}O)_2PNH-CH_2-CH_2Cl$ ‖ O	153—153.5 (1.4)	1.0552	1.4495	76.21	76.68	10.56, 10.45	10.36	60.5

tions of the residue gave 4.5 g (65.7%) of a liquid, b.p. 104-105° (1 mm); d_4^{20} 1.0157; n_D^{20} 1.4439; Found MR 65.97; Calculated MR 66.52

Found %: P 12.70; 12.62
$C_{12}H_{27}N_2O_3P$. Calculated %: P 12.30

3. Addition of Ethyl Bromide to Diethyl 2-Diethylaminoethylphosphoramidate (I). A mixture of 1.6 g of the substance (I) with a large excess of ethyl bromide (3 ml) was allowed to stand at room temperature; after several hours crystals began to form. After five days the excess of ethyl bromide was removed, and 2.25 g of crude crystals were obtained (98% yield). After recrystallization from ethyl bromide the substance melted at 135-137° (the crystals became wet before melting); a further recrystallization did not effect the melting point.

Found %: P 8.42; 8.77
$C_{13}H_{30}BrN_2O_3P$. Calculated %: P 8.59

4. Reaction of Diethyl Ethylenephosphoramidate (I) with Benzenethiol. A solution of 10 g of the substance (I) and 6.15 g of benzenethiol in 50 ml of carbon tetrachloride was stirred at room temperature for seven hours, after which the mixture was set aside overnight. On the next day the contents of the flask were heated to 50° and stirred at this temperature for one hour. When the solvent was distilled off, the starting substances were obtained together with a small amount of a substance of b.p. 105-115° (4 mm). The substances were mixed together again and heated under reflux at 80-85° for seven hours. Two fractionations from an Arbuzov flask gave a fraction of b.p. 195-198° (2 mm); n_4^{20} 1.5288; d_D^{20} 1.1655; Found MR 76.45; Calculated MR 76.43. The yield was 62%.

Found %: P 10.74; 10.79
$C_{12}H_{28}NO_3PS$. Calculated %: P 10.73

5. Synthesis of Dialkyl 2-Chloroethylphosphoramidates. The conditions of the synthesis were not changed. A solution of 6.6 g (0.153 mole) of ethylenimine in 25 ml of chloroform was dropped into a solution of 30.7 g (0.153 mole) of dipropyl phosphorochloridate in 75 ml of chloroform (which was cooled to −15°) for 50 minutes with stirring. The mixture was maintained at a temperature of from −15° to 0° for one hour, after which the cooling bath was removed and the mixture was set aside at room temperature overnight. Chloroform was distilled off under reduced pressure. Two distillations from an Arbuzov flask gave fairly pure Substance 3 (Table 2) in 72.5% yield.

SUMMARY

1. By the action of ethylenimine on dialkyl phosphorochloridates in presence of triethylamine, the corresponding dialkyl ethylenephosphoroamidates were prepared in high yield.

2. A study was made of the products obtained by reaction of diethyl ethylenephosphoramidate with diethylamine and with benzenethiol.

3. It was shown that the reactivity of the ethylenimine ring is lowered by replacement of the imine hydrogen by the dialkoxyphosphinyl group.

4. By the action of ethylenimine on dialkyl phosphorochloridates in absence of a base, the corresponding dialkyl 2-chloroethylphosphoramidates were prepared.

COMMUNICATION 1

P. M. Aronovich and B. M. Mikhailov

Among the numerous investigations devoted to the study of the nature of active nitrogen and its afterglow, only a few are concerned with the action of active nitrogen on organic substances. In 1911 Strutt [1] showed by means of qualitative experiments that active nitrogen reacts with organic substances with formation of hydrogen cyanide and, in some cases, a dark-colored resinous substance that formed on the walls of the vessel. Also, in the reaction with benzene the odors of benzonitrile and phenyl isocyanide were detected. Much later, in 1938 [2], diphenylacetylene, benzonitrile, tetrahydronaphthalene, and isoprene were submitted to the action of active nitrogen. The authors again observed the formation of hydrogen cyanide, which was determined quantitatively, and a macromolecular deposit, which contained 16-28% of nitrogen. In the course of the last five years there has appeared a series of papers by Winkler and coworkers, who made a detailed investigation of the reactions of active nitrogen with various aliphatic hydrocarbons, namely, methane and ethane [3], propane [4], butane and isobutane [5], ethylene [6], propene [7], isobutene [8], and acetylene [9]. The rates of formation of the reaction products were determined.

It will be seen that, as yet, the reactions of active nitrogen with organic substances have been studied for only a very limited number of cases. We considered it to be of interest to extend the range of these compounds to some extent with the object of comparing the reactivities of organic substances of various classes toward active nitrogen. As a criterion in the appraisal of the reactivities of the substances we took the amount of nitrogen that reacted. A study was made of the action of active nitrogen on certain hydrocarbons, carbonyl compounds, carboxylic acids, and esters. In these reactions the formation of hydrogen cyanide was observed, and in some cases there was also a dark-colored deposit, which formed on the walls of the reaction vessel. Also, some reaction products condensed, together with the original substance, in traps cooled with liquid nitrogen.

Stearic and oleic acids and oleic and phthalic esters were treated in the liquid state with active nitrogen. Under these conditions only a very small amount of hydrogen cyanide was obtained (a few milligrams per hour). On the other hand, the reaction of active nitrogen with acetic acid in the form of vapor was considerably more vigorous: the amount of hydrogen cyanide formed was almost ten times as great as in the reaction with liquid stearic acid, even though the latter experiment was carried out at a high temperature. This increase in the amount of hydrogen cyanide formed cannot be attributed to the difference in reactivity between acetic and stearic acids, but is clearly determined by the difference in state of aggregation: when atomic nitrogen passes through a liquid, its concentration must fall sharply owing to recombination.

In experiments with vapors a cylindrical tube was used at first, but later the tube was replaced by a [illegible] sphere. It was found that in the sphere, i.e. with reduction in the degree of deactivation of nitrogen on the walls of the vessel, the amount of hydrogen cyanide formed was increased to several times the amount formed in the tube. These results show that the formation of hydrogen cyanide occurs in the gas space. It must be pointed out the relatively large amount of hydrogen cyanide formed is accompanied by only traces of cyanogen.

The deposit is formed exclusively on the walls of the reaction vessel. In appearance and properties the deposit is similar to the polymerization product of hydrogen cyanide, and also to the cyanogen polymer obtained by Syrkina and Shekhter [10] by passing a discharge through cyanogen. If the deposit that we obtained were also a polymerization product of HCN or CN, then its formation should have been observed in the reactions of active nitrogen with all organic substances. It was actually found that the deposit was formed only in

reactions with unsaturated and aromatic compounds. The only exception was cyclohexanone, which, however, formed considerably less deposit than benzaldehyde, benzene, naphthalene, and cyclohexene. It is evident that, in the formation of the deposit, radicals or molecules other than HCN and CN take part, and this is confirmed also by the atomic ratio of carbon to nitrogen. For example, in the solid reaction product from benzene C : N is approximately 2, and in the product from cyclohexene there are almost four carbon atoms to each nitrogen atom. Apart from C, H, and N, the deposits contain silicon (the presence of which is probably to be explained by the formation of silicon nitrides in the discharge tube) and oxygen, traces of which are present in the nitrogen entering the system. When the deposits were hydrolyzed with 30% caustic potash solution, 82-84% of the nitrogen contained in the deposits was eliminated as ammonia. The comparatively ready elimination of ammonia indicates that the deposits probably contain imine or nitrile groups. Versteeg and Winkler [9], who base their views on other considerations, also believe that the deposit obtained in the reaction between acetylene and active nitrogen contains nitrile groups.

The identification of the reaction products condensed in the cooled traps would undoubtedly be of interest, but the investigation of these products is greatly complicated by the fact that they are formed in extremely small amount. Moreover, in certain cases and particularly in the reaction with benzaldehyde, the mixture of products is so complex that we have been unable to isolate pure substances. We succeeded in isolating and identifying some of the reaction products that collected in the traps only in the experiments with benzene, naphthalene (see Communication 2), and cyclohexanone.

In the reaction with cyclohexanone we isolated relatively large amounts of its cyanohydrin, which was formed by the addition of HCN to unchanged ketone. It would be expected that in the reaction between active nitrogen and benzaldehyde the corresponding cyanohydrin would again be formed, but we were unable to isolate any. Boiling of the mixture of products with hydrochloric acid yielded a little of a substance that was probably mandelic acid.

The liquids that were treated with active nitrogen became darker in color, became more viscous, and absorbed nitrogen to the extent of several percent. From the product obtained by treating oleic acid with active nitrogen, a little stearic acid was isolated. It is evident that the action of active nitrogen resulted in the elimination of hydrogen, which then hydrogenated the oleic acid. A similar phenomenon was observed previously [11] when oleic acid was subjected to a glow discharge in an atmosphere of air or nitrogen. This observation is also in accord with the results of Winkler and coworkers [6-8] on the formation of saturated hydrocarbons during the treatment of ethylenic hydrocarbons with active nitrogen.

The results of all the experiments carried out are given in the Table, but in an examination of these results it should be borne in mind that it is difficult to compare the experiments on liquids with the remaining experiments, in which the substances reacted in the vapor state. Moreover, the duration of the first experiments was only 10-15 hours, whereas we later increased the duration to 40-50 hours because we considered that the average values so obtained would represent the actual values more accurately.

For the experiments on liquids, a comparison based on the amount of hydrogen cyanide formed indicates that the presence of a double bond in the molecule of a carboxylic acid greatly raises its reactivity toward active nitrogen (compare the results on oleic and stearic acids) and that esters of aromatic carboxylic acids are more stable to active nitrogen than esters of unsaturated aliphatic acids. The data on the reaction with benzaldehyde cannot be regarded as complete, for products that condensed in the traps in fairly large amounts were not investigated.

A comparison of the total amounts of nitrogen reacting (Column 14 in the table) shows that cyclohexene reacts most readily with active nitrogen; then follows hexane and cyclohexane; and of the hydrocarbons investigated, benzene is the most stable to the action of active nitrogen (the experiments with naphthalene were inconclusive, owing to the inadequate amount of its vapor present in the reactor). The higher reactivity of hexane, as compared with cyclohexane, indicates that cyclization confers stability on the substance.

EXPERIMENTAL

Nitrogen was passed from a cylinder, through a drying system, over heated copper turnings, and finally to the discharge tube. The working p.d. of the tube was 2100-2500 v and the average current was 140-180 ma;

TABLE

No.	Substance		Form of reaction	Duration of reaction (hours)	Amount of ingoing nitrogen (g)	Products formed				Amount of nitrogen that reacted					Notes

the pressure was 10-15 mm. In reactions with liquids, the glowing glass, after leaving the discharge tube, was bubbled through the substance, which was contained in a test tube placed at a distance of 18 cm from the anode of the discharge tube.

In reactions with gaseous substances, the reaction vessel was either a tube (diameter 2.5 cm) or a sphere (diameter 12 cm). The vapor of the substance passed into the reaction vessel at a distance of 18 cm from the discharge through the capillary end of a glass tube sealed into the reaction vessel and provided with a tap. In the reaction with naphthalene, the substance was poured into the sphere so as to form a thin layer. In the experiments on cyclohexane and benzaldehyde the substances were again evaporated directly in the sphere, into which they were introduced in the form of small drops.

In the course of a single day, the reaction was continued for 5-7 hours. The discharge was then switched off, and the volatile reaction products were driven from the traps into an absorption vessel containing 5% caustic potash solution; the resulting solution was titrated with 0.1 N silver nitrate by Liebig's method. If a deposit formed on the walls during the reaction, then at the end of the whole experiment the reaction sphere or tube was filled with methanol and set aside for two days, after which the undissolved part of the deposit was readily scraped off. Some heat was evolved when active nitrogen reacted with the various substances, and the reaction was carried out at 25-30°.

Experiments with Oleic Acid. After the reaction the test tube contained a brown viscous oil having a green fluorescence; it was treated with ether. The ether solution was shaken with dilute caustic soda solution, and acidification of the aqueous layer yielded a light-yellow precipitate (35 mg), which melted at 63-64° after crystallization from methanol; in admixture with stearic acid it melted at 64-65°.

Experiments with Cyclohexene. In order to determine cyanogen, after an eight-hour reaction the volatile products were distilled into absorption vessels containing silver nitrate solution. The gases leaving these vessels were passed into absorption vessels containing caustic potash solution. The amount of cyanogen found was 6.78 mg, i.e. 0.84 mg/hour. A weighed amount (0.2556 g) of the deposit on the walls was dissolved in 10 ml of 30% caustic potash solution, and the solution was boiled for 25 hours, the liquid that distilled over being collected in 50 ml of 0.1 N HCl. Constant volume of the solution heated was maintained by addition of water. Found 0.03514 g N (82.1% on the amount taken).

Experiments with Benzene. In order to determine cyanogen, after an eight-hour reaction the volatile products were absorbed in 5% aqueous ammonia. One half of the solution from the absorption vessels was evaporated down: the dry residue weighed 3.6 mg, which corresponds, when calculated for the whole volume, to 5.6 mg of cyanogen, i.e. 0.7 mg/hour. The other half of the solution was titrated with silver nitrate solution, and the result corresponded to 364 mg. of hydrogen cyanide in the whole volume. The alcohol-insoluble deposit contained 48.78% C, 5.59% H, 26.41% N, and 5.3% of ash; 0.1516 g of it was boiled for 20 hours with 10 ml of 30% caustic potash solution. Found 0.0335 g N (84% on the amount taken).

Sulfuric acid was added to the alkaline solution remaining in the flask until the mixture was acid in reaction. The voluminous precipitate that formed was soluble in concentrated caustic potash solution. It did not burn or char, and it did not give a qualitative reaction for molybdenum *. It was soluble in a mixture of sulfuric and hydrofluoric acids, and the resulting solution evaporated away completely when heated.

Experiments with Naphthalene. When the alcohol-insoluble deposit (0.1336 g) was hydrolyzed, 0.0213 g N (84.4% on the amount taken) was distilled off as ammonia. In order to prove the presence of ammonium chloride in the solution, 400 ml was evaporated to dryness; weight of residue 0.71 g. Crystallization from water gave a white crystalline substance, which sublimed readily above 300°.

Experiments with Cyclohexanone. Hydrogen cyanide was distilled from the contents of the cooled traps, which were then washed out with cyclohexanone. The resulting solution was vacuum-distilled. A colorless oil (1.11 g) was collected at 97° (3 mm).

* It is possibly meant that it did not give a molybdate reaction (for silica). — Translator.

Found %: C 67.31; H 8.04; N 10.94

$C_7H_{11}ON$. Calculated %: C 67.16; H 8.86; N 11.19

The residue from the distillation was a dark-brown viscous liquid containing 12.58% N.

A mixture of 0.5 g of the cyclohexanone cyanohydrin so obtained and 1.5 ml of concentrated hydrochloric acid was boiled for three hours. The cooled reaction mixture was extracted with ether. The residue remaining after removal of ether was dissolved in sodium carbonate solution, and the solution was washed with ether and acidified. Crystallization from a benzene-hexane mixture gave 0.16 g of 1-hydroxycyclohexanecarboxylic acid, m.p. 105-106° (the literature [12] gives 106-107°).

Found %: C 57.82; H 8.38

$C_7H_{12}O_3$. Calculated %: C 58.30; H 8.32

A mixture of 0.15 g of the cyclohexanone cyanohydrin, 0.15 g of cyclohexanone, and 1 ml of concentrated hydrochloric acid was allowed to stand for two days at room temperature. The precipitate of white crystals was filtered off and dried (0.14 g, m.p. 193-195°); after crystallization from alcohol it melted at 193.5-194.5° (Ultee [13] gives m.p. 194° for 1-(1-hydroxycyclohexyloxy) cyclohexanecarbonitrile).

Found %: C 69.72; H 9.52; N 6.15

$C_{13}H_{21}O_2N$. Calculated %: C 69.92; H 9.48; N 6.27

Experiments with Benzaldehyde. The contents of the traps were washed out with benzene, and the resinous residue was filtered off. The solution was washed with sodium carbonate solution, and benzene was distilled off down to a volume of about 10 ml. Concentrated hydrochloric acid (3 ml) was added to the residue, and the mixture was boiled for three hours. The benzene layer was treated with sodium carbonate solution, and this solution was then acidified and extracted with ether. Ether was removed, and crystallization of the residue from benzene gave white crystals, m.p. 107-111°; a mixture of this substance with benzoic acid melted at 83-88°.

SUMMARY

1. Comparison of the reactivities of some organic compounds toward active nitrogen showed that these compounds can be placed in the following series of diminishing reactivity: cyclohexene > hexane > cyclohexane > benzene > cyclohexanone > acetic acid > butyl oleate > dibutyl phthalate > oleic acid > stearic acid.

2. The main product in the reactions of active nitrogen with the organic compounds investigated was found to be hydrogen cyanide, the formation of which occurred in the general reaction space. Only traces of cyanogen were formed.

3. When unsaturated and aromatic compounds were treated with active nitrogen, solid substances containing 16-20% of nitrogen were formed on the walls of the vessel. In the alkaline hydrolysis of these substances, almost the whole of their nitrogen is eliminated as ammonia.

4. When cyclohexanone was treated with active nitrogen, a small deposit of cyclohexanone cyanohydrin was formed in addition to hydrogen cyanide.

5. Reaction between active nitrogen and oleic acid resulted in the formation of stearic acid.

DEHYDROCHLORINATION OF TRICHLORO(CHLOROALKYL)- AND TRICHLORO(DICHLOROALKYL)-SILANES. REARRANGEMENT OF 1,1,1,2,4,4,4-HEPTACHLORO-1,4-DISILABUTANE DURING DEHYDROCHLORINATION WITH ALUMINUM CHLORIDE

A. D. Petrov, V. F. Mironov, and D. Mashantsker

One method of synthesizing unsaturated organosilicon compounds consists in the elimination of HX from various halogen-containing organosilicon compounds. Ushakov and Itenberg [1], using this method, were the first to prepare the unsaturated silahydrocarbon $(C_2H_5)_3SiCH=CH_2$, HCl being eliminated with aid of alcoholic alkali from $(C_2H_5)_2SiClCH_2Cl$. This method was later modified by the replacement of alcoholic alkali by quinoline [2] or aluminum chloride [3]. These latter reagents enabled the scope of the method to be widened, for they can be applied to the dehydrochlorination of compounds in which both chloroalkyl groups and chlorine atoms are attached to silicon. However, the possibility of the extensive application of these reagents, particularly aluminum chloride, for dehydrochlorination has received extremely inadequate study. Moreover, there are no comparative data on their application. Only for one compound ($Cl_3SiCH_2CH_2Cl$) has dehydrochlorination been carried out both with quinoline [4] and with aluminum chloride [3].

Apart from the example cited above, aluminum chloride has been successfully applied to the dehydrochlorination of only three compounds: 1-, 2-, and 3-chloropropyltrichlorosilanes [5].

It is known also that, under the action of aluminum chloride, some 1-, 2-, and 3-chloroalkylsilanes undergo intramolecular rearrangement or decomposition instead of elimination of HCl [4, 6, 7]. The present investigation was undertaken with the object of determining the limits of the applicability of aluminum chloride and quinoline and of obtaining comparative material on the dehydrochlorination of the same compounds by both reagents.

TABLE 1

No.	Reagent		$AlCl_3$				Quinoline [8]		
	Original substance	Position of Cl	Product	Position of Cl	Yield (%) at 500 mm	Yield (%) at 100 mm	Product	Position of Cl	Yield (%)
1	$Cl_3SiCCl_2CH_3$	1,1	$Cl_3SiCCl=CH_2$	1	78	67	$Cl_3SiCCl=CH_2$	1	58
2	$Cl_3SiCH(CH_3)CH_2Cl$	1,2	$Cl_3SiCH=CHCl$	2	0	47	$Cl_3SiCCl=CH_2$	2	30.5
3	$Cl_3SiCH_2CHCl_2$	2,2	$Cl_3SiCH=CHCl$	2	78	52	$Cl_3SiCH=CHCl$	2	50

We distilled 1,1-, 1,2-, and 2,2-dichloroethyltrichlorosilanes in presence of aluminum chloride (the dehydrochlorination of these compounds with quinoline has been carried out recently by Sommer and coworkers [8]). The results obtained are shown in Table 1.

It is important to note that the yields of 1- and 2-chlorovinyltrichlorosilanes (No. 1 and 3) are 60% higher in presence of aluminum chloride than in presence of quinoline, and it is particularly notable that the two reagents give different results in the dehydrochlorination of trichloro (1, 2-dichloroethyl) silane (No. 2)*.

The dehydrochlorination of compounds No. 1 and 2 was effected by distilling them under reduced pressure in presence of catalytic amounts of aluminum chloride from a flask fitted with a fractionating column. When these experiments were carried out at atmospheric pressure, the yields of trichloro (chlorovinyl) silanes were reduced and the amount of silicon tetrachloride formed was increased. However, in the case of trichloro (1,2-dichloroethyl) silane, dehydrochlorination occurred only when the distillation was at atmospheric pressure.

Bailey and Pines [5] showed that the three trichloro (chloropropyl)silanes give high yields of mixture of allyl- and propenyl-trichlorosilanes when dehydrochlorinated with aluminum chloride. We attempted the dehydrochlorination with quinoline both of 2- and 3-chloropropyltrichlorosilanes and also of trichloro(2-chloro-2-methylpropyl) – and trichloro (3-chloro-2-methylpropyl)-silanes, which we have synthesized for the first time. It was found that the 2-chloro isomers gave, respectively, trichloropropenylsilane (61%) and trichloro (2-methylpropenyl) silane (70%), but HCl was not eliminated from the 3-chloro isomers.

Attempts to dehydrochlorinate dichloro(3-chloropropyl) methylsilane and (1-chloroethyl) triethylsilane by means of quinoline were also unsuccessful: after refluxing $(C_2H_5)_2SiCHClCH_3$ with quinoline for ten hours, only about 10% of $(C_2H_5)_2SiCH=CH_2$ was obtained. Agre [9] finds that $Cl_2SiCHClCH_3$, treated with quinoline, gives $Cl_2SiCH=CH_2$ in only 13% yield. The dehydrochlorination of trichloro(3-chloro-2-methylpropyl) silane with aluminum chloride resulted in the formation of a 1 : 1 mixture of 2-methylallyl- and 2-methylpropenyl-trichlorosilanes:

$$Cl_3SiCH_2\underset{CH_3}{C}HCH_2Cl \xrightarrow{AlCl_3} Cl_3SiCH_2\underset{CH_3}{C}=CH_2 + Cl_3SiCH=\underset{CH_3}{C}-CH_3.$$

When dichloro(3-chloropropyl) methylsilane was treated with aluminum chloride, it was decomposed almost quantitatively to CH_3SiCl_3. Comparative results on dehydrochlorination with quinoline and with aluminum chloride are given in Table 2.

Hence, it will be seen from our results and the data in the literature that quinoline is mainly suitable for the dehydrochlorination of chloro(2-chloroalkyl) silanes, which it converts exclusively into compounds having the double bond in the 1-position. On the other hand, aluminum chloride, which eliminates HCl not only from 2-chloroalkyl-, but also from 1- and 3-chloroalkyl-trichlorosilanes, gives a mixture of compounds in which the double bond is in the 1- and 2-positions. However, even if only one of the three chlorines attached to silicon in 1-, 2-, and 3-choloroalkyltrichlorosilanes is replaced by an alkyl radical, the use of aluminum chloride is already impossible: elimination of HCl does not occur, but the 1-chloroalkyl compounds may undergo rearrangement or decomposition [6] and the 2- and 3-chloroalkyl compounds may undergo so-called β- and γ-breakdown [4, 7].

Interesting results were obtained in the dehydrochlorination – both with quinoline and with aluminum chloride – of 1,1,1,2,4,4,4-heptachloro-1,4-disilabutane (V). When quinoline was used, a 70% yield was obtained of 1,2-bistrichlorosilylethylene [1,1,1,4,4,4-hexachloro-1,4-disilabut-2-ene] (XIII), m.p. 36.1°, which was then methylated to 1,2-bistrimethylsilylethylene [2,2,5,5-tetramethyl-2,5-disilahex-3-ene] (XIV) (see scheme of reactions below). However, the physical properties of (XIV), as compared with those of its structural analogs containing single and triple bonds, and particularly its high exaltation of molecular refraction (+ 0.83) (Table 3) at first caused us to doubt the purity of the product, in spite of the satisfactory analytical data.

* Pyrolysis of this compound at 610° gives a mixture of 1- and 2-chlorovinyltrichlorosilanes in 43% yield [9].

The synthesis of this compound was therefore carried out by another method: the condensation of $(CH_3)_2SiCH=CHCl$ with $(CH_3)_3SiCl$ in presence of sodium.

TABLE 2

No.	Original compound	Reagent: Quinoline — Product	Quinoline — Yield (%)	Reagent: $AlCl_3$ — Product	$AlCl_3$ — Yield (%)
1	$Cl_2SiCH_2CHClCH_3$	$Cl_2SiCH=CHCH_3$	61	$Cl_2SiCH=CHCH_3$ / $Cl_2SiCH_2CH=CH_2$ } 2 : 1[5]	53.5
2	$Cl_2SiCH_2CH_2CH_2Cl$	Original compound	—	$Cl_2SiCH=CHCH_3$ / $Cl_2SiCH_2CH=CH_2$ } 3 : 1[5]	68
3	$Cl_2SiCH_2C(CH_3)_2$ (Cl)	$Cl_2SiCH=C(CH_3)_2$ (CH$_3$)	76.5	—	—
4	$Cl_2SiCH_2CHCH_2Cl$ (CH_3)	Original compound	—	$Cl_2SiCH=C(CH_3)_2$ / $Cl_2SiCH_2C=CH_2$ (CH_3) } 1 : 1	47
5	$CH_3Cl_2SiCH_2CH_2CH_2Cl$	Original compound	—	CH_3SiCl_3	85
7	$(C_2H_5)_2SiCHClCH_3$	$(C_2H_5)_2SiCH=CH_2$	10		

By an analogous method we synthesized the isomer of (XIV), 1,1-bistrimethylsilylethylene [2,2,4,4-tetramethyl-3-methylene-2,4-disilapentane] (XV). (2-Chlorovinyl) trimethylsilane was prepared by the methylation of $Cl_2SiCH=CHCl$.

It should be noted that, on analogy with $Cl_2SiCH_2CH_2Cl$, which is decomposed by CH_3MgBr with formation of ethylene and $(CH_3)_4Si$[12], it might be expected that the methylation of $Cl_2SiCH=CHCl$ would not go. However, both the methylation of $Cl_2SiCH=CHCl$ and the Wurtz reaction of the resulting $(CH_3)_2SiCH=CHCl$ with $(CH_3)_3SiCl$ went without any decomposition of the molecule - a difference in behavior not only from $Cl_2SiCH_2CH_2Cl$, but also from compounds of the type M–CH=CHCl [13] (M may be Pb, Sn, and other metals), which are decomposed with elimination of ethylene and acetylene respectively under the action of various reagents, including RMgX.

TABLE 3

Formula of substance	B.p. (°C)	n_D^{20}	d_4^{20}	MR found	MR calculated	Δ
$(CH_3)_2SiCH_2CH_2Si(CH_3)_2$ [10]	150—151	1.4204	0.7536	58.00	58.43	+0.17
$(CH_3)_2SiCH=CHSi(CH_3)_2$	145	1.4310	0.7589	58.79	57.96	+0.83
$(CH_3)_2SiC\equiv CSi(CH_3)_2$ [11]	134	1.4200	0.7703	58.65	56.82	−0.17

Comparison of the properties of the isomers (XIV) and (XV) showed that they are greatly different. The compound (XIV) shows a high exaltation of MR, whereas (XV) shows practically none. Moreover, whereas the characteristic Raman lines for (XIV) are fairly intense and have breadths of up to 20 cm^{-1}, these lines can scarcely be observed in the spectrum of (XV). The rate of addition of thiocyanogen to (XIV) was found to be ten times as high as that for (XV). Finally, whereas no polymer could be obtained from (XIV) in presence of a peroxide, even at a pressure of 5500 atm, (XV) gave a pentamer under these conditions.

When (V) was distilled with aluminum chloride, the dehydrochlorination product was a liquid (m.p. from −10 to + 10°). This was methylated, and the Raman and infrared spectra of the product were investigated (by Yu. P. Egorov); it was thus shown that the product was a mixture of (XIV) and (XV).

The hypothesis that (XIII) could isomerize into (XVI) under the influence of aluminum chloride was not confirmed, for distillation of (XIII) with aluminum chloride, even at atmospheric pressure (~195°), did not affect its melting point, and subsequent methylation of the product gave only (XIV). We must conclude, therefore, that the dehydrochlorination of 1,1,1,2,4,4,4-heptachloro-1,4-disilabutane with aluminum chloride is accompanied by partial isomerization of the 1,2-substituted carbonium ion into the more stable 2,2-substituted carbonium ion [3, 5]:

EXPERIMENTAL

Trichloroisobutylsilane $CH_3CHCH_2SiCl_3$ (I)

A solution of isobutylmagnesium bromide, prepared in 1.3 liters of ether from 85 g of magnesium and 530 g of isobutyl bromide, was added with stirring and cooling to a mixture of 665 g of silicon tetrachloride and 500 ml of ether contained in a three-liter flask. On the next day the contents of the flask were boiled for five hours and then filtered from the precipitate of magnesium salt. Ether was distilled from the filtrate, and the residue was distilled through a column. The product, which came over at 140-142°, was 359 g of the substance (I); yield 54%; b.p. 140.6° (746); n_D^{20} 1.4349; d_4^{20} 1.1590; Found MR 43.11; Calculated MR 43.06.

Trichloro(1-chloro-2-methylpropyl)silane $CH_3CHCHSiCl_3$ (II)
CH_2Cl

Trichloro(2-chloro-2-methylpropyl)silane $CH_3C(Cl)CH_2SiCl_3$ (III)
CH_3

Trichloro(3-chloro-2-methylpropyl)silane $CH_2CHCH_2SiCl_3$ (IV)
CH_2Cl

Substance (I) (356 g) was placed in the flask of the apparatus [14]. Chlorination was continued until the temperature in the flask reached 174° (28 hours). Three distillations through a column gave four fractions: Fraction I, b.p. 140-143°, was 109 g of unchanged (I); Fraction II, b.p. 161-164°, 27 g, n_D^{20} 1.4668; d_4^{20} 1.2665, was the 1-chloro compound (II), apparently mixed with dehydrochlorination products (found MR 49.50, calculated MR 47.90); Fraction III, b.p. 179-181°, 34 g, was the 2-chloro compound (III), b.p. 179.5° (740 mm), n_D^{20} 1.4660; d_4^{20} 1.3110; Found MR 47.74; Calculated MR 47.90; Fraction IV, b.p. 191-192°, 138 g, was the 3-chloro isomer (IV), b.p. 192.0° (740 mm), n_D^{20} 1.4680; d_4^{20} 1.3114, Found MR 47.92; Calculated MR 47.90; the yield of monochlorinated products was 77%.

The chlorinations referred to below were carried out similarly.

1,1,1,2,4,4,4-Heptachloro-1,4-disilabutane $Cl_3SiCHCH_2SiCl_3$ (V)
Cl

The chlorination of 343 g of 1,1,1,4,4,4-hexachloro-1,4-disilabutane was continued for 26 hours, in the course of which the temperature in the flask rose to 221°. Distillation through a column gave 123 g of the original substance, b.p. 200-202°, and 230 g of (V), b.p. 224-225°. The yield of (V) on the amount of hexachloro-disilabutane that reacted was 94%. M.p. −40 ± 5°; b.p. 225.0° (737 mm); n_4^{20} 1.4915; d_4^{20} 1.5774; Found MR 60.89; Calculated MR 61.05.

Trichloro(1,1-dichloroethyl)silane $CH_3Cl_2CSiCl_3$ (VI)

Trichloro(1,2-dichloroethyl)silane $ClCH_2ClCHSiCl_3$ (VII)

Trichloro(2,2-dichloroethyl)silane $Cl_2CHCH_2SiCl_3$ (VIII)

A. Trichloro(1-chloroethyl)silane [15] (482 g) was chlorinated for 18 hours, in the course of which the temperature in the flask rose to 151°. Distillation gave 225 g of the original 1-chloroethyl compound, b.p. 136.8° and n_D^{20} 1.4646, 167 g of (VI), b.p. 151.8°, and 100.5 g of (VII), b.p. 181° (760 mm); n_D^{20} The yield of (VI) and (VII) was 88.5%, the relative amounts of the isomers being 1 : 0.6.

B. Trichloro(2-chloroethyl)silane [15] (1265 g) was chlorinated for 53 hours, in the course of which the temperature in the flask rose to 174°. Distillation gave 269 g of the original 2-chloroethyl compound and 1080 g of a difficultly separable mixture of (VII) and (VIII), b.p. 170-180°, yield 92.5%. Pure (VIII) was obtained with the aid of sulfuryl chloride [8]; b.p. 175° (740 mm); n_D^{20} 1.4800; d_4^{20} 1.5201; Found MR 43.43; Calculated MR 43.48.

Trichloro(1-chlorovinyl)silane $CH_2{=}ClCSiCl_3$ (IX)

A. A mixture of 78 g of (VI) and 1 g of aluminum chloride was distilled at the usual rate at a pressure of 200-250 mm from a flask fitted with a column (300 mm in height, 20 mm in diameter) filled with porcelain rings 3-4 mm in diameter. Fractionation of the distillate through a column gave 2 ml of a fraction of b.p. 100-124°, 32 ml of a fraction of b.p. 124-127°, and 2.5 ml of a fraction of b.p. 127-140°. A yield of 51 g (77.9%) of (IX) was obtained; it had b.p. 124.6° (739 mm); n_D^{20} 1.4650; d_4^{20} 1.4243; Found MR 38.00; Calculated MR 38.17. The literature [8] gives b.p. 124°.

B. A mixture of 57 g of (VI) and 0.5 g of aluminum chloride was distilled at atmospheric pressure. The yield of (IX) was 32.2 g (67%). Subsequent experiments on dehydrochlorination with aluminum chloride were carried out under similar conditions.

Trichloro(2-chlorovinyl)silane ClCH=CHSiCl$_3$ (X)

A. A mixture of 97 g of (VIII) and 1 g of aluminum chloride was distilled at 300 mm. The yield of (X) was 64 g (78.2%); b.p. 133-136°.

B. Distillation of 57 g of (VIII) in presence of 0.5 g of aluminum chloride at atmospheric pressure gave 25g (52.1%) of (X), which came over at 133-135°. It had b.p. 133° (731 mm); n_D^{20} 1.4750; d_4^{20} 1.4364; Found MR 38.37; Calculated MR 38.17. The literature [8] gives b.p. 134°.

C. A mixture of 58 g of (VII) and 0.5 g of aluminum chloride was distilled at atomospheric pressure. The product was 23 g (47%) of (X), b.p. 133-135° and n_D^{20} 1.4751; yield 47%.

(2-Chlorovinyl)trimethylsilane ClCH=CHSi(CH$_3$)$_3$ (XI)

A solution of methylmagnesium iodide in 1 liter of ether was prepared from 43 g of magnesium and 300 g of methyl iodide, and it was stirred while 99 g of (X) was added over a period of one hour. The mixture was boiled for four hours, and on the next day the product was decomposed by addition of water. The ether layer, combined with ether extracts of the aqueous layer, was dried with calcium chloride. Distillation through a column gave 42 g (52%) of (XI), b.p. 116.6° (741 mm); n_D^{20} 1.4380; d_4^{20} 0.8921; Found MR 39.63; Calculated MR 39.28.

	Found %:	C 44.73; 44.6;	H 8.33; 8.30;	Cl 26.80; 26.70;	Si 20.63; 20.45
$C_5H_{11}ClSi$.	Calculated %:	C 44.59;	H 8.31;	Cl 26.33;	Si 20.83

(1-Chlorovinyl)trimethylsilane CH$_2$=ClCSi(CH$_3$)$_3$ [8] (XII)

To methylmagnesium iodide prepared in 1 liter of ether from 45 g of magnesium and 320 g of methyl iodide, 100 g of (IX) was added over a period of one hour. After a one-hour boil and the usual treatment, distillation through a column gave 42 g (61%) of (XII), b.p. 104°.

1,2-Bistrichlorosilylethylene [1,1,1,4,4,4-Hexachloro-1,4-disilabut-2-ene] Cl$_3$SiCH=CHSiCl$_3$ (XIII)

A mixture of 167 g of (V) and 85 g of quinoline was distilled from a 250-ml flask up to a temperature of 210°. Redistillation through a column gave 110 g (74%) of (XIII), b.p. 190.5° (740 mm), m.p. + 36.1°.

	Found %:	C 7.96; 8.26;	H 0.95; 0.85;	Si 19.13; 18.78
$C_2H_2Cl_6Si_2$.	Calculated %:	C 8.15;	H 0.68;	Si 19.03

Dehydrochlorination of (V) with N,N-diethylaniline gave a 58% yield of (XIII). The dissolution of 1,2-bistrichlorosilylethylene in ether is accompanied by considerable cooling. The substance slowly absorbs bromine.

1,2-Bistrimethylsilylethylene [2,2,5,5-Tetramethyl-2,5-disilahex-3-ene] (CH$_3$)$_3$SiCH=CHSi(CH$_3$)$_3$ (XIV)

A. Methylmagnesium iodide was prepared in 300 ml of ether from 24.3 g of magnesium and 170 g of methyl iodide, and to the resulting solution melted (XIII) (42 g) was added dropwise. The ether was distilled off, and the residue in the flask was heated in a boiling water bath for more than nine hours. The ether that had been distilled off was then returned to the flask, and the contents were decomposed with water and given the usual treatment. Distillation through a column gave 22 g (89.5%) of (XIV), b.p. 145.0° (760 mm); m.p. −18.5°; n_D^{20} 1.4310; d_4^{20} 0.7589; Found MR 58.79; Calculated MR 57.96.

	Found %:	C 56.06; 55.99;	H 11.82; 11.69;	Si 32.59; 32.35
$C_8H_{20}Si_2$.	Calculated %:	C 55.74;	H 11.69;	Si 32.55

Δ ν (cm^{-1}): 183 (2), 228 (1), 325 (2), 610 (20), 683 (1), 698 (3), 789 (0), 842 (0), 1248 (1), 1258 (1), 1295 (3), 1387 (0), 1412 (1), 1551–1570 (2), 2900 (10), 2982 (2), 2961 (10).

B. Sodium (10 g) was melted in 60 ml of boiling isooctane and converted into dust with the aid of a rapidly rotating stirrer. When the mixture was cool, addition was made of 250 ml of ether, 25 g of chlorotrimethylsilane, about 2 ml of (XI), and, after 10 minutes, 0.5 ml of ethyl acetate. After one minute reaction set in accompanied by steady boiling of the ether, and the reaction was maintained by addition of 27 g of (XI) over a period of two hours. The contents of the flask were boiled further for four hours, and on the next day they were filtered from salt, which was washed with fresh ether. The residue remaining after distillation of ether was fractionated through a column and gave 34 g (76%) of (X), b.p. 145.5° (750 mm); n_D^{20} 1.4308; d_4^{20} 0.7591; Found MR 58.76; Calculated MR 57.96. The Raman spectrum was completely identical with the spectrum of (XIV) obtained by method A.

1,1-Bistrimethylsilylethylene [2,2,4,4-tetramethyl-3-methylene-2,4-disilapentane] $[(CH_3)_3Si]_2C=CH_2$ (XV)*

Ether (500 ml), chlorotrimethylsilane (20 g), (XII) (1 ml), and ethyl acetate (about 1.5 ml) were added to 9 g of sodium granulated in 30 ml of toluene. When reaction had begun, 23.5 g of (XII) was added in such a way that the ether boiled steadily. After a 2.5 hour boil and the usual treatment, distillation through a column gave 14 g (46.5%) of (XV), b.p. 151.6° (757 mm); m.p. below −70°; n_D^{20} 1.4374; d_4^{20} 0.7823; Found MR 57.76; Calculated MR 57.96.

Found %: C 55.97; 55.99; H 11.50; 11.58; Si 32.55; 32.57
$C_8H_{20}Si_2$. Calculated %: C 55.74; H 11.69; Si 32.55

Δ ν (cm^{-1}): 229 (4), 419 (2), 472 (5), 586 (2), 646 (7), 694 (4), 1251 (3), 1401 (2), 1418 (2), 1422 (2), 2898 (10), 2969 (10), 3014 (3).

1,1- and 1,2-Bistrichlorosilylethylenes $Cl_3SiCH=CHSiCl_3$ and $Cl_3SiC(SiCl_3)=CH_2$ (XVI)

A. A mixture of 225 g of (V) and 5 g of aluminum chloride was distilled at 10 mm. Redistillation through a column gave about 4 g of material boiling over the range 70-170° and 164 g (82%) of the substance (XVI), b.p. 190-195°; f.p. −8 to +9°; n_D^{20} 1.4862; d_4^{20} 1.5152; Found MR 55.90; Calculated 55.74.

B. A mixture of 21 g of (V) and 0.5 g of aluminum chloride was distilled at atmospheric pressure. The yield of (XVI) was 13 g (68.4%).

1,1- and 1,2-Bistrimethylsilylethylenes $(CH_3)_3SiCH=CHSi(CH_3)_3$ and $(CH_3)_3SiC(Si(CH_3)_3)=CH_2$ (XVII)

To a solution of methylmagnesium bromide prepared from 29 g of magnesium in 300 ml of ether, 59 g of (XVI) was added. On the next day the contents of the flask were boiled for seven hours. The mixture was decomposed with dilute hydrochloric acid, and distillation of the ether layer (dried with calcium chloride) through a column gave 16 g (46.5%) of (XVII), b.p. 145-148°; m.p. about −70°; n_D^{20} 1.4337; d_4^{20} .7702; Found MR 58.24; Calculated MR 57.96.

Found %: C 55.70; 55.80; H 11.70; 11.80; Si 32.27; 32.42
$C_8H_{20}Si_2$. Calculated %: C 55.74; H 11.69; Si 32.55

Δ ν (cm^{-1}): 225 (4), 321 (5), 418 (0), 472 (6), 548 (0), 608 (7), 646 (0), 695 (6), 830 (2), 845 (2), 1189

* The synthesis of (XV) was carried out by Glukhovtsev [16].

(3), 1253 (4), 1295 (1), 1404 (4), 1420 (4), 1570 (b), 2980 (10), 2967 (10), 3016 (2).

Thus the spectrum of (XVII) contains the frequencies of the compounds (XIV) and (XV), the most intense being: (XIV), 321, 608, 845, 1295, 1570; (XV), 472, 646, 830, 1404, 3016. In the infrared spectrum of (XVII) a band at 3.328 μ (3014 cm^{-1}) was observed; this characterizes unsymmetrical vibrations in the $=CH_2$ group. This frequency is absent in the spectrum of (XIV), but is very distinct in that of (XV).

Trichloropropenylsilane $CH_3CH=CHSiCl_3$ (XVIII)

A mixture of 87 g of trichloro(2-chloropropyl)silane [17] and 63 g of quinoline was distilled at the usual rate. Redistillation through a column gave 44 g (61%) of (XVIII), b.p. 123-126° and n_D^{20} 1.4513. The literature [5] gives b.p. 126° and n_D^{20} 1.4513.

Trichloro(2-methylpropenyl)silane $(CH_3)_2C=CHSiCl_3$ (XIX)

A mixture of 28 g of (III) and 19 g of quinoline gave 18 g (76.5%) of (XIX), b.p. 153° (739 mm); n_D^{20} 43.04. For trichloro (2-methylallyl) silane the literature [18] gives b.p. 140-141° (743 mm), n_D^{20} 1.4505; d_4^{20} 1.1784.

SUMMARY

1. The dehydrochlorination of the following compounds was carried out for the first time:

With the aid of quinoline: $Cl_3SiCH_2CHClCH_3$, $Cl_3SiCH_2CCl(CH_3)_2$ and $Cl_3SiCHClCH_2SiCl_3$.

With the aid of aluminum chloride: 1,1- 1,2- and 2,2-dichloroethyltrichlorosilanes, $Cl_3SiCH_2CH(CH_3)CH_2Cl$ and $Cl_3SiCHClCH_2SiCl_3$.

2. It was shown that, when quinoline was used, dehydrochlorination products were obtained in high yield only when the chlorine atom was in the β-position with respect to silicon, the products being exclusively 1-alkenylsilanes. Aluminum chloride can be applied for dehydrochlorination only in the case of trichloro(chloroalkyl)silanes, but the chlorine atom may be in the α-, β-, or γ-position.

3. A new arrangement in organosilicon chemistry was discovered.

In the dehydrochlorination of 1-chloro-1,2-bistrichlorosilylethane (1,1,1,2,4,4,4-heptachloro-1,4-disilabutane) with quinoline, only 1,2-bistrichlorosilylethylene was formed, whereas in dehydrochlorination with aluminum chloride the same product was obtained in admixture with 1,1-bistrichlorosilylethylene. A scheme is given in which an isomeric change in the skeleton of the original compound occurs in the course of the dehydrochlorination.

STEREOCHEMISTRY OF CYCLIC COMPOUNDS

COMMUNICATION 9. CONDENSATION OF 1-VINYL-1-CYCLOHEXENE WITH METHYL ACRYLATE

I. N. Nazarov, V. F. Kucherov, and G. M. Segal

It has now been established beyond doubt that diene condensations between monosubstituted dienes and unsymmetrical dienophiles can result in the formation of different stereoisomers, the relative amounts of which depend on the reaction temperature. In the condensation of 1-phenyl-1, 3-butadiene [1] and of trans-piperylene [2] with acrylic acid and its derivatives it was found, for the first time, that such diene syntheses can proceed in two sterically different directions a and b, and the amount of the trans-adduct, formed according to scheme b, increases with rise of temperature.

This relationship was established most clearly in a study of the condensation of trans-2,4-pentadienoic acid with acrylic acid [3]. Trans- adducts were obtained also in the reaction between various disubstituted 1,3-butadienes and acrylic acid [4], and also in the dimerization of 1-phenyl-1,3-butadiene [5] and its condensation with itaconic anhydride [6].

In our laboratory the formation of stereoisomers in diene syntheses with more complex polycyclic systems was observed in the condensation of various vinylcycloalkenes with α,β-unsaturated ketones [7]. We made our most detailed studies of the stereochemistry of the diene synthesis for the condensation of maleic and citraconic anhydrides with 1-vinyl-1-cyclohexene [8], and for the condensation of citraconic anhydride with 1,2,4a,5,8,8a-hexahydro-4a,7-dimethyl-4-vinylnaphthalene [9]. In these studies we established interesting stereochemical regularities in the behavior of o-dicarboxylic cyclic acids, particularly with respect to the steric selectivity of hydrogenation.

With the object of making a further study of the stereochemistry of hydrogenation and the steric directivity of the diene synthesis, we made a detailed study of the condensation of 1-vinyl-1-cyclohexene with methyl acrylate. A study of the reaction under different conditions showed that in this diene condensation a mixture of isomeric 1,2,3,5,6,7,8,8a-octahydro-1-naphthoic esters (I) and (II) is formed, the relative amounts of which being greatly dependent on temperature:

Hydrolysis of the mixture of esters (I) and (II) gave a mixture of the corresponding acids, and from this mixture, submitted to fractional crystallization, we succeeded in isolating the individual syn- and anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acids (III) and (IV) *, the relative amounts of which are shown in the in their dependence on the temperature of the diene condensation.

TABLE

Temperature (°C) and duration of condensation	Yield of adduct (%)	Amount (%) isolated after hydrolysis	
		of acid (III)	of acid (IV)
20°; 45 days	20	52	Not isolated
50°; 70 hours	16	52	8
80°; 24 hours	70	34	15
170°; 6 hours	98	26	32

At 50° the condensation of 1-vinyl-1-cyclohexene with methyl acrylate is very slow: after 70 hours a yield of about 16% of a liquid mixture of the esters (I) and (II) was obtained, and from this, after hydrolysis and crystallization, we isolated 52% of syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III), m.p. 142°, and only 8% of anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV), m.p. 96°. At 170° 1-vinyl-1-cyclohexene condenses very rapidly with methyl acrylate: after six hours a 96% yield was obtained of a mixture of the esters (I) and (II), and from this, after hydrolysis and crystallization, we isolated only 26% of the syn acid (III), whereas the yield of the anti acid (IV) was now 32%. The rest of the acid remained in the form of a liquid mixture of isomers. The separation of the isomeric liquid esters (I) and (II) does not appear to be feasible, and they were prepared in the pure state by esterifying the pure crystalline acids (III) and (IV) with diazomethane. The increase in the amount of the anti isomer (IV) with rise in the temperature of the diene condensation is not associated with the thermal isomerization of the syn isomer (I), for this ester is not converted into the corresponding anti isomer (II) when heated at 230° for two hours: when the product is hydrolyzed, more than 50% of the original syn acid (III) is recovered and about 20% of a crystalline substance of undetermined structure, m.p. 184-185°, is obtained.

In order to prove that the isomeric esters (I) and (II), and also the corresponding acids (III) and (IV), are epimers with respect to hydrogen at C-8a, we have investigated their isomerization and hydrogenation, which made it possible to pass, after replacement of carboxyl by amino, to the known decahydro-1-naphthylamines, the spatial configurations of which have been established. It was found that methyl syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoate (I) was isomerized to anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV) in good yield when boiled with sodium methoxide in methanol. Under similar conditions methyl anti-1,2,3,5,6,7,8,8a-octahydro-1-napthoate (II) did not isomerize at all, since the hydrogen atoms at C-1 and C-8a in this compound are already in the trans configuration. It was thus established that the ester (I) and the acid (III) are indeed syn isomers having a cis arrangement of the hydrogens at C-1 and C-8a, whereas the ester (II) and the acid (IV) belong to the anti series and have a trans arrangements of the hydrogens at C-1 and C-8a.

* The nomenclature and representation of stereoisomers are based on those for tetradecahydrophenanthrene [10].

The isomeric syn and anti acids (III) and (IV), and also the corresponding esters (I) and (II), are readily hydrogenated over a platinum catalyst under the usual conditions, which indicates the normal 4-position of the double bond, corresponding to the normal scheme of the diene synthesis. The characteristic feature of this hydrogenation is its strict steric selectivity, which we have pointed out previously [8]: as a result, only one of the possible stereoisomers is formed. It was found that hydrogenation of syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III) gave cis-syn-decahydro-1-naphthoic acid (V), m.p. 125°, identical with the substance previously assigned this formula [11]. The same acid was formed by hydrolysis of the cis-syn ester (VI), which was obtained by hydrogenation of the syn ester (I). In order to provide further confirmation of the spatial configuration of the cis-syn acid (V), it was converted with the aid of sodium azide (Schmidt reaction) into the known cis-syn-decahydro-1-naphthylamine (VII), identified as the benzoyl derivative [12].

These results completely confirm the configuration of the syn acid (III) and prove that in its hydrogenation, and also in the hydrogenation of the ester (I), addition of hydrogen proceeds selectively from the side opposite to the carboxy group (less screened). Only in this case will the saturated acid (V) have a cis-syn configuration with the equatorial disposition of the carboxyl, which accounts for the inability of its ester (VI) to undergo isomerization under the action of sodium methoxide.

Similar transformations were carried out also on the isomeric anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV). Its hydrogenation over a platinum catalyst gave the individual trans-anti-decahydro-1-naphthoic acid (VIII), m.p. 88° (amide, m.p. 220-221°), which was formed also by the hydrolysis of the saturated ester (IX) obtained by hydrogenation of the anti ester (II). The trans-anti configuration of the saturated acid (VIII) is proved quite reliably by the fact that treatment with sodium azide in accordance with the Schmidt reaction converts it into the known trans-anti-decahydro-1-naphthylamine (X), identified by the melting points of its acetyl and benzoyl derivatives [12]. It follows that the hydrogenation of (II) and (IV) also proceeds from the side opposite to the carboxyl and results in the formation of the acid (VIII) and the ester (IX), which belong to the trans-decahydronaphthalene series.

For trans-anti-decahydro-1-naphthoic acid (VIII) the literature [11] gives m.p. 102°, but the constants of its derivatives (amide and decahydro-1-naphthylamine) are identical with our values. The fact that the amide of m.p. 220-221° can be reconverted in high yield into the trans-anti acid (VIII) of m.p. 88° (and not 102°) shows that the previously described method [11] of preparing trans-anti-decahydro-1-naphthoic acid (VIII) was not stereospecific, and the acid of m.p. 102° contained the cis-syn acid (V) as impurity. This is confirmed by the fact that artificially prepared mixtures of the isomeric acids (V) and (VIII) have sharp melting points in the range 90-120° (the actual value depending on the relative amounts of the acids) and, for practical purposes, cannot be separated by crystallization.

The isomeric acids (III) and (IV) react quite differently with hydrogen chloride in glacial acetic acid.

Under these conditions, syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III) is converted quantitatively into the cis-lactone (XI), whereas anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV) gives the chloro acid (XII). The structure of the latter as a product of the addition of hydrogen chloride at the double bond (with chlorine at C-4a) follows from the fact that its chlorine atom is very mobile and is readily eliminated by the action of alkali. The liquid mixture of acids then formed absorbs only about one-half of a molecular equivalent of hydrogen when hydrogenated over a platinum catalyst at room temperature. A small amount of the trans-anti acid (VIII) was isolated from the liquid hydrogenation product. It is probable, therefore, that elimination of hydrogen chloride from the chloro acid (XII) proceeds in the two possible directions, so that the original anti acid (IV) is accompanied by about the same amount of the isomeric acid (XIII), which has an intercycle double bond and cannot be hydrogenated under the usual conditions. We did not succeed in isolating the acid (XIII) in the pure state, and we did not study its chemical properties.

The different behaviors of the syn and anti acids (III) and (IV) in the lactonization reaction and the above-discussed selective hydrogenation of these acids into acids of the cis- and trans-decahydronaphthalene series can be explained in a graphic manner by reference to molecular models *.

It follows quite obviously from these models that the syn acid (III) should have a high tendency to undergo lactonization and should give only cis-syn-decahydro-1-naphthoic acid (V) when hydrogenated, owing to addition of hydrogen from the least screened side. Unlike the syn acid, the anti acid (IV) gives trans-anti-decahydro-1-naphthoic acid (VIII) when hydrogenated, and it is incapable of undergoing lactonization, but can readily undergo addition of hydrogen chloride at the double bond.

EXPERIMENTAL

Condensation of 1-Vinyl-1-cyclohexene with Methyl Acrylate

a) A solution of 70 g (40% excess) of 1-vinyl-1-cyclohexene and 40 g of methyl acrylate in 70 ml of dry benzene was boiled in presence of a little pyrogallol for 24 hours. Benzene was distilled off, and vacuum distillation of the residue gave 61.5 g (70% on the methyl acrylate) of liquid adduct, b.p. 125-127° (10 mm) and n_D^{19} 1.4960.

Found %: C 74.50; 74.48; H 9.31; 9.41
$C_{12}H_{18}O_2$. Calculated %: C 74.14; H 9.34

The adduct was hydrolyzed by boiling it with 185 ml of 20% caustic potash solution until solution was complete. The solution was filtered and acidified with hydrochloric acid. The oil that separated partially crystal-

* The symbol (e) denotes an equatorial disposition of a substituent, and the symbol (p) a polar disposition.

lized after one day. The crystals were pressed on the filter to remove oil and were washed several times with petroleum ether. The product, amounting to 25.4 g, melted at 137-139°. Crystallization from a 2 : 1 mixture of diethyl ether and petroleum ether gave 19.7 g (34.5%) of pure syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III), m.p. 141-142°.

Found %: C 73.0; 72.94; H 8.80; 8.95
$C_{11}H_{16}O_2$. Calculated %: C 73.29; H 8.95

The amide of the syn acid (III), which was prepared as usual through the acid chloride, melted after crystallization from ethanol at 218-219°.

Found %: C 73.72; 73.68; H 9.53; 9.56; N 7.57; 7.65
$C_{11}H_{17}NO$. Calculated %: C 73.74; H 9.49 N 7.82

The solution remaining after the separation of the syn acid (III) was evaporated to low bulk and set aside at 0° for two days. The crystals that separated were filtered off, the product (5.5 g) being the isomeric anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV), m.p. 95-97°. Vacuum distillation of the liquid residue gave 21 g of a liquid mixture of acids, b.p. 134-136° (1.5 mm), from which a further 3.5 g of the anti acid (IV), m.p. 91-95°, was isolated by dissolving the mixture in petroleum ether and cooling the solution in a freezing mixture. Crystallization from petroleum ether gave 8.7 g (15.3%) of anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV) of constant melting point (96-97°).

Found %: C 73.42; 73.48; H 9.07; 8.85
$C_{11}H_{16}O_2$. Calculated %: C 73.29; H 8.95

The amide of the anti acid (IV), which was prepared in the usual way, had m.p. 202-203° (from ethanol).

Found %: C 73.58; 73.49; H 9.41; 9.53
$C_{11}H_{17}NO$. Calculated %: C 73.74; H 9.49

The residue from the separation of the crystalline isomers was vacuum-distilled and gave 17.6 g of a thick liquid, b.p. 135-137° (2 mm). Very slow partial crystallization occurred. The substance was not investigated further.

b) A solution of 10 g of 1-vinyl-1-cyclohexene, 5.7 g of methyl acrylate, and 0.1 g of pyrogallol in 10 ml benzene was set aside at room temperature for 45 days. Benzene was distilled off, and vacuum distillation of the residue was 2.5 g of a liquid adduct, b.p. 124-125° (11 mm) and n_D^{25} 1.4956. The product was hydrolyzed at the boil with 12 ml of 20% caustic potash solution (three hours) and the solution was acidified with hydrochloric acid. The liquid acids so obtained crystallized partially when allowed to stand. The crystals were washed on the filter with a little petroleum ether. The solid product, amounting to 1.2 g (51.7%), was syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III), m.p. 139-141°, identical with the product obtained in the preceding experiment. Owing to its small amount, the liquid product was not investigated.

c) A solution of 31.8 of 1-vinyl-1-cyclohexene, 18.1 g of methyl acrylate, and 0.1 g of pyrogallol in 35 ml of benzene was heated at 50° for 70 hours. Vacuum distillation gave 6.6 g of adduct, b.p. 126-128° (12 mm) and n_D^{25} 1.4940, and this, by hydrolysis, treatment as before, and crystallization from a 2 : 1 mixture of diethyl ether and petroleum ether, gave 3.2 g of pure syn acid (III), m.p. 141-142°. The mother liquor, after evaporation, dissolution in a little petroleum ether, and freezing, gave 0.7 g of a crystalline mixture melting at 90-92°. Crystallization of this from petroleum ether gave 0.5 g of anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV), m.p. 96-97°, identical with the product obtained in the first experiment.

d) A solution of 10 g of 1-vinyl-1-cyclohexene and 5.7 g of methyl acrylate in 10 ml of benzene was heated in presence of pyrogallol in a metal ampoule at 170° for six hours. Vacuum distillation gave 12.9 g (98%) of a liquid adduct, b.p. 118-120° (9 mm) and n_D^{17} 1.4970. This, after hydrolysis and treatment as before gave 3.1 g (20%) of the syn acid (III), m.p. 140-141°. From the mother liquor, after two freezing treatments,

4.0 g of crystals, m.p. 90-92°, was obtained; crystallization of these from petroleum ether gave 3.7 g (32%) of pure anti acid (IV), m.p. 95-96°.

Methyl syn-1,2,3,5,6,7,8,8a-Octahydro-1-naphthoate (I)

A solution of 5 g of syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III), m.p. 141-142°, was treated with an ethereal solution of diazomethane. Vacuum distillation gave 5.0 g of the syn ester (I), b. p. 124-125° (9 mm); n_D^{20} 1.4960; d_4^{20} 1.0450; Found MR 54.22; Calculated MR 54.65.

Found %: C 73.92; 74.07 H 9.47; 9.29
$C_{12}H_{18}O_2$ Calculated %: C 74.14; H 9.34

Hydrolysis of the syn ester (I) with boiling 20% caustic potash solution gave a good yield of the original syn acid (III), m.p. 140-141°.

Methyl anti-1,2,3,5,6,7,8,8a-Octahydro-1-naphthoate (II)

In a similar way, 6 g of anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (IV), m.p. 96-97°, was treated with an ethereal solution of diazomethane, and distillation gave 6.1 g of the anti ester (II), b.p. 120° (9 mm) n_D^{20} 1.4945; d_4^{20} 1.0380; Found MR 54.48; Calculated MR 54.67.

Found %: C 74.02; 74.25; H 9.23; 9.31
$C_{12}H_{18}O_2$ Calculated %: C 74.14; H 9.34

Hydrolysis of the anti ester (II) gave a quantitative yield of the original anti acid (IV), m.p. 95-96°.

Isomerization of Methyl syn-1,2,3,5,6,7,8,8a-Octahydro-1-naphthoate (I)

Methyl syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoate (I) (6.0 g) was added to a solution of 18 g of sodium in 400 ml of absolute methanol, and the mixture was boiled for 18 hours. Methanol was distilled off under reduced pressure, and 130 ml of water was added to the residue. After being boiled for three hours, the mixture was filtered and then carefully acidified to Congo red with hydrochloric acid. Product was 5.4 g of an acid of m.p. 90-92°, and crystallization from petroleum ether gave 4.7 g (84.5%) pure anti-1,2,3,5,6,7,8,8a-octahydro--1naphthoic acid (IV), m.p. 96-97°, undepressed by admixture of sample prepared by hydrolysis of the diene-synthesis products.

cis-syn-Decahydro-1-naphthoic Acid (V)

The syn acid (III) (4.4 g) was dissolved in methanol (40 ml) and hydrogenated over platinum oxide. One molecular equivalent of hydrogen (600 ml, 20°) was absorbed. After removal of catalyst, distillation of the methanol, and washing of the crystalline residue with petroleum ether, 4.2 g of the known cis-syn acid (V), m.p. 123-125°, was isolated (the literature gives m.p. 125°). The amide prepared from this acid in the usual way melted after crystallization from ethanol at 238-239° (the literature gives m.p. 238°).

Methyl cis-syn-Decahydro-1-naphthoate (VI)

The syn ester (I) (5 g) was dissolved in methanol (25 ml) and hydrogenated over a platinum catalyst. One molecular equivalent of hydrogen (690 ml. 20°) was absorbed. Distillation gave 4.7 g of the cis-syn methyl ester (VI), b.p. 123-124° (9 mm); n_D^{20} 1.4825, d_4^{20} 1.0180; Found MR 54.95; Calculated MR 54.87.

Found %: C 73.24; 73.12; H 10.08; 9.96
$C_{12}H_{20}O_2$ Calculated %: C 73.42; H 10.21

The same cis-syn ester (VI) was prepared in quantitative yield by treating the cis-syn acid (V), m.p. 125°, with diazomethane. Hydrolysis of the cis-syn ester (VI) with boiling 20% caustic potash solution gave a yield of about 90% of the pure original cis-syn acid (V), m.p. 124-125°.

cis-syn-Decahydro-1-naphthylamine (VII)

Concentrated sulfuric acid (17.5 ml) was added to a solution of 1.6 g of the cis-syn acid (V), m.p. 124–125°, in 44 ml of chloroform, the mixture was heated to 40°, and 1 g of sodium azide was added gradually with vigorous stirring. Stirring was continued at 50° for 90 minutes, and the mixture was cooled and poured into 50 ml of water. The aqueous layer was separated, extracted with ether, and saturated with caustic soda. The amine that separated was extracted with ether, the ether layer was dried with sodium sulfate, and the ether was distilled off. The cis-syn-decahydro-1-naphthylamine (VII) so obtained was benzoylated in the usual way by addition of 2 ml of benzoyl chloride and 30 ml of 5% caustic soda solution. A product (1.7 g) of m.p. 190–195° was obtained, and one crystallization of this from ethanol gave 1.2 g of pure N-(cis-syn-decahydro-1-naphthyl) benzamide, m.p. 206-207°, which is in accord with data in the literature [12].

trans-anti-Decahydro-1-naphthoic Acid (VIII)

The anti acid (IV) of m.p. 97° (4.8 g) was dissolved in methanol (30 ml) and hydrogenated over platinum oxide. One molecular equivalent of hydrogen was absorbed. The crystalline hydrogenation product (4.8 g), which was isolated after removal of catalyst and solvent, melted at 75-78°. Crystallization from low-boiling petroleum ether gave 3.3. g of pure trans-anti-decahydro-1-naphthoic acid (VIII), which had a constant melting point of 87-88°. Repeated crystallization from petroleum ether or aqueous methanol did not effect its melting point.

Found %: C 72.23; 72.36; H 9.99; 9.98
$C_{11}H_{18}O_2$. Calculated %: C 72.49; H 9.96

Amide of the Acid (VIII)

Oxalyl chloride (2 ml) was added to a solution of 2.4 g of the trans-anti acid (VIII), m.p. 87-88°, in 25 ml of absolute benzene and the mixture was heated at 30° for 45 minutes. Benzene and excess of oxayl chloride were removed under reduced pressure, and the residue—an ethereal solution of the acid chloride—was added with stirring to 10 ml of aqueous ammonia at 0°. The product was 2.3 g of the amide of the trans-anti acid (VIII), m.p. 214-216°, and after crystallization from a 2 : 1 mixture of ethanol and chloroform it had a constant melting point of 220-221°, which is in accord with the literature [11] (m.p. 222°).

In order to reconvert the product into the trans-anti acid (VIII), a mixture of 0.5 g of amide, m.p. 220–221°, and 3 ml of concentrated sulfuric acid was cooled to 0°, and a solution of 1.7 g of sodium nitrite in 8 ml of water was added gradually with stirring, the mixture then being heated over 15 minutes at 60° and poured into 30 ml of ice water. The precipitate that formed was filtered off, washed with water, and dissolved in 10 ml of 5% caustic soda solution. The solution was filtered, and acidification gave 0.45 g of crystalline acid (VIII), which after being washed with water and dried had m.p. 86-87.5° undepressed by admixture of the above-described sample.

Methyl trans-anti-Decahydro-1-naphthoate (IX)

The anti ester (II) (2.9 g) was dissolved in methanol (20 ml) and hydrogenated over a platinum catalyst. One molecular equivalent of hydrogen (380 ml, 20°) was absorbed. Distillation gave 2.7 g of the trans-anti ester (IX), b.p. 118–119° (9 mm) n_D^{20} 1.4778, d_4^{20} 1.0160; Found MR 54.62; Calculated MR 54.87

Found %: C 73.19; 73.27; H 10.24; 10.19
$C_{12}H_{20}O_2$. Calculated %: C 73.42; H 10.21

Hydrolysis of the trans-anti ester (IX) so obtained gave an 80% yield of pure original trans-anti acid (VIII), m. p. 86–88°.

trans-anti-Decahydro-1-naphthylamine (X)

By the reaction already described, 2.4 g of the trans-anti acid (VIII), m.p. 86-88°, gave 1.5 g of trans-anti-decahydro-1-naphthylamine (X). Benzoylation of 0.7 g of this amine by the usual method and crystallization of the product gave 0.75 g of N-(trans-anti-decahydro-1-naphthyl) benzamide, m.p. 192-193° (the

literature [11] gives 195°). In order to acetylate the amine, a solution of 0.7 g of (X) in 7 ml of absolute benzene and 7 ml of acetic anhydride was boiled for 90 minutes. The solution was evaporated to dryness, and the crystalline residue was washed on the filter with petroleum ether. The product was 0.55 g of N-(trans-anti-decahydro-1-naphthyl) acetamide, which was crystallized from petroleum ether (b.p. 50-70°), and then melted at 185-186° (the literature [11] gives m.p. 182°.

cis Lactone (XI)

A solution of 2 g of syn-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid (III) in 20 ml of glacial acetic acid was saturated with dry hydrogen chloride and heated for one hour at 60°. Acetic acid was distilled off under reduced pressure. Washing of the crystalline residue on the filter yielded 1.2 g of the cis lactone (XI), m.p. 78-79°. We succeeded in isolating a further 0.35 g of cis lactone, m.p. 76-78° from the mother liquor. After crystallization from a 1 : 3 mixture of diethyl ether and petroleum ether, the pure cis lactone (XI) had m.p. 80-81°.

Found %: C 73.52; 73.40; H 8.87; 9.04
$C_{11}H_{16}O_2$. Calculated %: C 73.29; H 8.95

Chloro Acid (XII)

A solution of 3 g of anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acid in 30 ml of glacial acetic acid was saturated with dry hydrogen chloride and heated for one hour at 60°. Acetic acid was distilled off under reduced pressure, and the crystalline residue was washed on the filter with petroleum ether. The product was 2.2 g of the chloro acid (XII), m.p. 147-149°, which, after being crystallized from a 1 : 1 mixture of diethyl ether and petroleum ether, had a constant melting point of 154-155°.

Found %: C 61.33; 61.16 H 7.88; 7.82; Cl 17.0
$C_{11}H_{17}O_2Cl$. Calculated %: C 61.32; H 7.87; Cl 16.35

A solution of 4 g of the chloro acid (XII) in 40 ml of 5% caustic soda solution was boiled for five minutes, and then acidified. The oil that separated was extracted with ether. Vacuum distillation gave 3.2 g of a liquid mixture of acids, b.p. 132-134° (2 mm), n_D^{20} 1.5115. When this mixture was hydrogenated in methanol over a platinum catalyst, only 0.5 of a molecular equivalent of hydrogen was absorbed, after which hydrogen came to a complete stop. Methanol was distilled off under reduced pressure, and the liquid residue (n_D^{20} 1.5050) was dissolved in the minimum amount of petroleum ether. On standing, the solution gave 0.2 g of trans-anti-decahydro-1-naphthoic acid (VIII), m.p. 83-85°, undepressed by admixture of a sample obtained in a previous experiment (above).

SUMMARY

1. A study was made of the condensation of 1-vinyl-1-cyclohexene with methyl acrylate. Hydrolysis of the product gives a mixture of syn- and anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acids (III) and (IV), and it was shown that with rise in the condensation temperature the amount of the anti isomer (IV) increases with simultaneous decrease in the amount of the syn isomer (III).

2. The spatial configurations of syn- and anti-1,2,3,5,6,7,8,8a-octahydro-1-naphthoic acids (III) and (IV) were established by converting them into known decahydro-1-naphthylamines; they are epimers with respect to the hydrogen at C-8a.

3. It was shown that the hydrogenation of the isomeric acids (III) and (IV), and also of the corresponding esters (I) and (II), is sterically selective and occurs from the side opposite to the carboxyl with formation of acids (V) and (VIII), and also esters (VI) and (IX), of the cis- and trans-decahydronaphthalene series respectively.

4. It was shown that the isomeric syn and anti acids (III) and (IV) behave differently under lactonization conditions. An examination of molecular models has enabled us to explain the stereochemical peculiarities of the epimers that we have obtained.

SYNTHESIS OF STEROID COMPOUNDS AND RELATED SUBSTANCES

COMMUNICATION 37. SYNTHESIS OF STERIOD ANALOGS NOT CONTAINING A B RING

I. N. Nazarov and S. I. Zavyalov

In recent years data have been reported on the hormone activity of some compounds of the 2-phenylnaphthalene type (I) [1], (II) [2], and (III) [3], which can be regarded as structural analogs of steroid hormones in which the C rings have been removed:

(I) (II) (III)

In this connection it appeared to be of interest also to investigate the effect on the hormone activity of the absence of the B ring in the molecules of estrone, androsterone, and related substances.

With this object we decided to synthesize compounds of the types (V) and (VII), which can be regarded as analogs of 13-nor-D-homoestrone (IV) and 18, 19-bisnor-D-homo-4-androsten-3,17-dione (VI), from which their structures are obtained by removal of the B rings.

(IV) (V) (VI) (VII)

Reaction of the methiodide of 3-dimethylamino-4'-methoxypropiophenone (VIII) or of 4'-methoxyacrylophenone (IX) with the sodium derivative of ethyl 2-methyl-4-oxo-2-cyclohexene-1-carboxylate (Hagemann's ester) (X) in methanol solution gave the corresponding addition product (XI), which, without isolation in the pure state, was treated successively with boiling aqueous-methanolic caustic potash and dilute hydrochloric acid. In these

treatment, as a result of an intramolecular condensation of the crotonic type, hydrolysis, decarboxylation and partial dehydrogenation, a mixture was formed of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII) and 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), which are steroid analogs without D rings.

In order to prove the structures of these ketones, some of their physical properties were examined and 2--phenylnaphthalene derivatives obtained from them were identified with compounds synthesized independently. When heated with sulfur at 200-210° for a short time, the methoxy ketone (XII) was readily dehydrogenated to the 3,4-dihydro-1(2H)-naphthalenone (XVI), which was completely aromatized at a higher temperature (250-260°) in presence of palladized charcoal to the corresponding 1-naphthol derivative (XVII). When hydrogenated in methanol solution over a palladium catalyst, the methoxy ketone (XII) absorbed two molecular proportions of hydrogen and gave the octahydro-1(2H)-naphthalenone (XIII). Under the same conditions the dihydro-1(2H)--naphthalenone (XVI) was reduced to the tetrahydro-1-naphthol (XV), oxidation of which with chromic anhydride in acetic acid gave the original dihydro-1(2H)-naphthalenone (XVI).

Demethylation of the methoxy ketone (XVI) by means of aluminum chloride in boiling xylene gave a high yield of the phenol (XIV), which was reconverted by diazomethane in ethereal-methanolic solution into the original methoxy ketone (XVI). In the demethylation of the dienone (XII) under the same conditions, partial aromatization occured, and apart from a small amount of the phenol (XIV), we were unable to isolate any pure substances.

The 1-naphthol derivative (XVII) was converted by the action of diazomethane into 1-methoxy-8-p--methoxyphenylnaphthalene (XVIII), which we synthesized independently from 3,4-dihydro-5-methoxy-2(1H)--naphthalenone (XXI). Reaction of the last compound with p-methoxyphenylmagnesium bromide (XXII) followed by dehydration of the alcohol (XX) gave 1,2-dihydro-8-methoxy-3-p-methoxyphenylnaphthalene (XIX), which was dehydrogenated with sulfur at 220-225° into the diether (XVIII) referred to above.

The distribution of double bonds in the molecule of the dienone (XII) is in full accord with its ultraviolet spectrum • (Curve 1), which has two maxima at 372 mμ (ε $1.50 \cdot 10^4$) and 317 mμ (ε $1.11 \cdot 10^4$). The calculated absorption maximum of the dienone (XII) (374 mμ) agrees closely with the experimental results. The hypsochromic shift in the maximum which occurs when we pass to the 3,4-dihydro-1(2H)-naphthalenone (XVI) (Curve 2; λ_{max} 311 mμ; ε $3.33 \cdot 10^4$) indicates the lower degree of conjugation in the molecule of this ketone.

Reduction of the tricyclic anisole derivatives (XII), (XIII), and (XIX) by means of lithium in liquid ammonia [5] opens the way to the preparation of a series of hydroaromatic steroid analogs of the type (VII).

EXPERIMENTAL

Methiodide of 3-Dimethylamino-4'-methoxypropiophenone (VIII). The hydrochloride of 3-dimethylamino-4'-methoxypropiophenone (25 g, m.p. 180-181°) [6] was added in portions to an ice-cooled, stirred mixture of 25 g of caustic potash, 150 ml of water, and 700 ml of ether. When the precipitate had redissolved, the ether layer was separated, and 44 g of methyl iodide was added to it. In the course of 12 hours at room temperature, 74 g (76%) of the methiodide of 3-dimethylamino-4'-methoxypropiophenone (VIII) was precipitated; it melted with decomposition at 178-181°.

Found %: I 36.18; 36.02

$C_{13}H_{20}O_2NI$. Calculated %: I 36.4

4'-Methoxyacrylophenone (IX). The methiodide of 3-dimethylamino-4'-methoxypripiophenone (VIII) (6 g) was heated at a bath temperature of 235-240° at a pressure of 1 mm. The product was 2.1 g (78%) of 4'-methoxyacrylophenone (IX), b.p. 128-131° (1 mm) and n_D^{20} 1.5820 [6].

Reaction of the Methiodide of 3-Dimethylamino-4'-methoxypropiophenone with the Sodium Derivative of Ethyl 2-Methyl-4-oxo-2-cyclohexene-1-carboxylate. The methiodide of 3-dimethylamino-4'-methoxypropiophenone (VIII) (74 g) was added gradually to an ice-cooled, stirred methanol solution of the sodium derivative prepared from 38 g of ethyl 2-methyl-4-oxo-2-cyclohexene-1-carboxylate (X) (b.p. 113-118° at 1 mm) and n_D^{20} 1.4880 [7], 4.5 g of sodium, and 100 ml of methanol. The mixture was stirred for four hours at room temperature. Methanol was then distilled off under reduced pressure, and the residue was treated with 100 ml of water and extracted with chloroform. A yield of 57 g was obtained of the crude condensation product (XI), n_D^{20} 1.5630.

Condensation of Ethyl 2-Methyl-4-oxo-2-cyclohexene-1-carboxylate with 4'-Methoxyacrylophenone. Ethyl 2-methyl-4-oxo-2-cyclohexene-1-carboxylate (X) (2.7 g) was added to an ice cooled, stirred solution of sodium methoxide prepared from 0.05 g of sodium and 3 ml of methanol, and a solution of 2.1 g of 4'-methoxyacrylophenone (IX) in 3 ml of ether was then added. After 30 minutes at room temperature the solution was treated with 10 ml of dilute (1:5) hydrochloric acid and extracted with ether. A yield of 4.2 g of the crude condensation product (XI), n_D^{20} 1.5632, was obtained.

Preparation of 3,4,7,8-Tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone and 3,4-Dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone. A mixture of 57 g of the above described crude condensation product (XI), 20 g of caustic potash, 100 ml of water, and 300 ml of methanol was refluxed for three hours. After acidification to Congo red with concentrated hydrochloric acid, the solution was boiled for another ten minutes.

• The ultraviolet spectra were determined in methanol solution on a spectrophotometer having a Dianov-Klokov attachment.

The solution was evaporated down to one-third bulk under reduced pressure. Extraction of the residue with chloroform gave 34 g of an oil boiling at 230-240° (1 mm), and when ether was added to this there was a precipitate of 4.7 g of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII), m.p. 106-107° (from a mixture of benzene and heptane), λ_{max} (in methanol) 372 mμ (ε $1.50 \cdot 10^4$) and 317 mμ (ε $1.11 \cdot 10^4$).

A solution of 6 g of caustic potash in 50 ml of water and 280 ml of methanol was added to the mother liquor remaining after the isolation of the dienone (XII), and the mixture was refluxed for four hours. The above-described treatment gave 20 g of an oil of b.p. 225-240° (1 mm), and when ether was added to this there was a precipitate of 4.5 g of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), m.p. 126-127° (from aqueous methanol); λ_{max} (methanol) 311 mμ (ε $3.33 \cdot 10^4$).

$C_{17}H_{16}O_2$. Calculated %: C 80.9 H 6.3

After being washed with methanol its 2,4-dinitrophenylhydrazone melted at 228-231° with decomposition.

Found %: N 13.18; 13.29
$C_{23}H_{20}O_5N_4$. Calculated %: N 12.9

From the mother liquor remaining after the separation of the dihydro-1(2H)-naphthalenone (XVI) a further 6 g of a crystalline mixture was precipitated, and by chromatography of this in ether on alumina, 2 g of dienone (XII) was isolated. Thus, the total yield of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII) was 6.7 g [12% on the methiodide of 3-dimethylamino-4'-methoxypropiophenone (VIII) taken].

Conversion of 3,4,7,8-Tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone into 3,4-Dihydro-6-p-methoxyphenyl 1(2H)-naphthalenone. A mixture of 0.5 g of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII) and 0.15 g of sulfur was heated at 200-210° for 30 minutes. By chromatography in ether on alumina, 0.25 g (50%) of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), m.p 126-127°, was isolated.

Dehydrogenation of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone. A mixture of 0.9 g of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI) and 0.9 g of palladized charcoal (10% Pd) was heated at 259-260° for 20 minutes. The cooled reaction mixture was extracted with hot 5% caustic soda solution. Filtration and acidification with dilute hydrochloric acid gave 0.24 g (27%) of 6-p-methoxyphenyl-1-naphthol (XVII), m. p. 156-157° (from aqueous methanol).

Found %: C 81.45; 81.52; H 5.72; 5.83
$C_{17}H_{14}O_2$. Calculated %: C 81.6; H 5.6

Hydrogenation of 3,4,7,8-Tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone. 3,4,7,8-Tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII) (2.5 g) was hydrogenated in methanol over palladium supported on calcium carbonate and absorbed 238 ml (2 molecular equivalents) of hydrogen (20°, 753 mm). The product was 1.5 g (60%) of octahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XIII), b.p. 210-215° (1 mm) and n_D^{20} 1.5602

Found %: C 79.12; 79.28; H 8.25; 8.41
$C_{17}H_{22}O_2$. Calculated %: C 79.0 H 8.4

After being washed with methanol, its 2,4-dinitrophenylhydrazone melted with decomposition at 198-200°; λ_{max} (in methanol) 379 mμ (ε 1.06·10⁴).

Found %: N 12.95; 13.12

$C_{28}H_{28}O_5N_4$. Calculated %: N 12.8

Reduction of 3,4-Dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone. 3,4-Dihydro-6-p-methoxy-1(2H)-naphthalenone (XVI) (0.5 g) was hydrogenated in methanol at 20° and atmospheric pressure over palladium supported on calcium carbonate. The product was 0.2 g (40%) of 1,2,3,4-tetrahydro-6-p-methoxyphenyl-1-naphthol (XV), m.p. 95-97° (from a mixture of benzene and heptane).

Found %: C 80.58; 80.44; H 7.09; 7.07

$C_{17}H_{18}O_2$. Calculated %: C 80.3; H 7.1

Oxidation of 1,2,3,4-Tetrahydro-6-p-methoxyphenyl-1-naphthol. A mixture of 0.4 g of 1,2,3,4-tetrahydro-6-p-methoxyphenyl-1-naphthol (XV), 0.4 g of chromic anhydride, and 20 ml of glacial acetic acid was allowed to stand at room temperature for one day. Methanol (2 ml) was added, and solvents were distilled off under reduced pressure. The residue was treated with 10 ml of water and extracted with chloroform. Chromatography of the reaction products in ether on alumina gave 0.14 g (35%) of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), m.p. 125-126°.

Demethylation of 3,4-Dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone. A mixture of 1 g of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), 2 g of aluminum chloride, and 10 ml of dry xylene was boiled with stirring for five minutes. The cooled mixture was treated with ice and with dilute (1 : 1) hydrochloric acid. The phenol then precipitated was dissolved in hot 5% caustic soda solution, and the solution was filtered and again precipitated with hydrochloric acid. The product was 0.4 g (43%) of 3,4-dihydro-6-p-hydroxyphenyl-1(2H)-naphthalenone (XIV), m.p. 214-215° (from aqueous methanol).

Found %: C 80.67; 80.88; H 6.16; 6.12

$C_{16}O_2H_{14}$. Calculated %: C 80.67; H 5.9

Methylation of 3,4-Dihydro-6-p-hydroxyphenyl-1(2H)-naphthalenone. 3,4-Dihydro-6-p-hydroxphenyl-1(2H)-naphthalenone (XIV) (0.2 g) was dissolved in methanol (10 ml), excess of ethereal diazomethane was added, and the mixture was set aside at room temperature for eight hours. After removal of solvents under reduced pressure, 0.15 g (71%) of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI), m.p. 126-127°, was obtained.

Demethylation of 3,4,7,8-Tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone. A mixture of 1 g of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII), 2 g of aluminum chloride, and 10 ml of dry xylene was boiled with stirring for five minutes. After treatment as before, 0.09 g of the above-described 3,4-dihydro-6-p-hydroxyphenyl-1(2H)-naphthalenone (XIV), m.p. 210-212°, was isolated.

Methylation of 6-p-Methoxyphenyl-1-naphthol. A mixture of 0.2 g of 6-p-methoxyphenyl-1-naphthol (XVII) and excess of ethereal diazomethane was allowed to stand for five hours at room temperature. After removal of solvent there remained 0.12 g (57%) of 1-methoxy-6-p-methoxyphenylnaphthalene (XVIII), m.p. 105-106° (from heptane).

Found %: C 81.73; 81.94; H 6.23; 6.37

$C_{18}H_{16}O_2$. Calculated %: C 81.8; H 6.1

$C_{18}H_{16}O_2 \cdot C_6H_3O_7N_3$. Calculated %: N 8.5

Preparation of 1,2-Dihydro-8-methoxy-3-p-methoxyphenylnaphthalene. A solution of 3.6 g of 3,4-dihydro-5-methoxy-2(1H)-naphthalenone (XXI), b.p. 123-125° (1 mm) and n_D^{20} 1.5610 [8], in 15 ml of benzene was added gradually to an ice-cooled stirred Grignard reagent prepared from 0.7 g of magnesium, 6 g of p-bromoanisole, and 20 ml of ether. The solution was refluxed for 90 minutes, allowed to stand for one day at room temperature, and then decomposed with ice and dilute (1 : 1) hydrochloric acid. The ether-benzene layer yielded 2.5 g of an oil, b.p. 200-215° (1 mm), which crystallized out when 80% acetic acid was added. The product was 1.2 g (23%) of 1,2-dihydro-8-methoxy-3-p-methoxyphenylnaphthalene (XIX), m.p. 94-95° (from heptane).

Found %: C 80.99; 80.73 H 6.70; 6.623;
$C_{18}H_{18}O_2$. Calculated %: C 81.2; H 6.8

Dehydrogenation of 1,2-Dihydro-8-methoxy-3-p-methoxyphenylnaphthalene. A mixture of 0.6 g of 1,2-dihydro-8-methoxy-3-p-methoxyphenylnaphthalene (XIX) and 0.2 g of sulfur was heated at 220-225° for 20 minutes. The cooled mass was extracted with a boiling mixture of benzene and heptane in presence of alumina. Filtration and removal of solvents gave 0.4 g (67%) of 1-methoxy-6-p-methoxyphenylnaphthalene (XVIII), m.p. 105-106°, undepressed by admixture of the sample described above.

SUMMARY

1. When the methiodide of 3-dimethylamino-4'-methoxypropiophenone (VIII) or 4'-methoxyacrylophenone (IX) was treated with the sodium derivative of Hagemann's ester (X), a condensation product (XI) was isolated, and boiling of this with aqueous-methanolic caustic potash and subsequent treatment with hydrochloric acid gave a mixture of 3,4,7,8-tetrahydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XII) and 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI). The structures of these compounds were confirmed by a study of their ultraviolet spectra and by independent synthesis.

2. Dehydrogenation of 3,4-dihydro-6-p-methoxyphenyl-1(2H)-naphthalenone (XVI) over palladized charcoal gave 6-p-methoxyphenyl-1-naphthol (XVII), which was converted into 1-methoxy-6-p-methoxyphenylnaphthalene (XVIII) by methylation with diazomethane. This compound was synthesized also by reaction of p-methoxyphenylmagnesium bromide (XXII) with 3,4-dihydro-5-methoxy-2(1H)-naphthalenone (XXI) and dehydration of the alcohol obtained (XX).

3. The tricyclic compounds (XII), (XIII), (XVI), and (XIX) that we have prepared are of interest as steroid analogs in which there is no B ring.

REDUCTION OF β-AMINO ACIDS WITH LITHIUM ALUMINUM HYDRIDE

V. M. Rodionov* and V. V. Kiseleva

In 1948-49 Karrer and coworkers [1] applied lithium aluminum hydride to the reduction of esters of α-amino acids and showed that the reaction is not accompanied by change in spatial configuration and results in the formation of optically pure β-amino alcohols. In 1952-53 lithium aluminum hydride was applied successfully by Vogl and Pohm [2, 3] to the preparation of β-amino alcohols directly from α-amino acids. When α-amino acids free from other functional groups were treated with a 3-5% solution of $LiAlH_4$ in tetrahydrofuran, the yields of the corresponding β-amino alcohols attained 70-80%.

As we were studying β-amino acids, we also made use of $LiAlH_4$ for their direct reduction to γ-amino alcohols. We carried out this reaction on the following β-amino acids: β-aminohydrochinnamic acid, β-amino-3,4-methylenedioxyhydrocinnamic acid, 3-aminononanoic acid, β-aminocyclohexanepropionic acid, and 3-aminobutyric acid. In this way we obtained the corresponding amino alcohols: 3-amino-3-phenyl-1-propanol, 3-amino-3-(3,4-methylenedioxyphenyl)-1-propanol, 3-amino-1-nonanol, γ-aminocyclohexanepropanol, and 3-amino-1-butanol. It was thus shown that the direct reduction of the carboxy group with lithium aluminum hydride is possible also for β-amino acids.**

EXPERIMENTAL

The reductions with $LiAlH_4$ were carried out both in tetrahydrofuran and in ether; in some cases– e.g. in the case of β-aminohydrochinnamic acid– the yield of amino alcohol was the same in both solvents. The $LiAlH_4$ solution was prepared either from the dry preparation or directly from aluminum chloride and lithium hydride [4, 5]; when it was prepared from aluminum bromide [6], low yields were obtained.

1. Reduction of β-Aminohydrocinnamic Acid. In an atmosphere of nitrogen, 3.3 g of $LiAlH_4$ was added to 66 ml of dry tetrahydrofuran, and the mixture was cooled and stirred while 5.7 g of β-aminohydrocinnamic acid was added gradually. The mixture was heated for three hours in a water bath. On the next day the mixture was diluted with an equal volume of dry ether; it was then cooled strongly, and moist ether was added very cautiously; finally, water was added dropwise. The precipitate that formed was filtered off and boiled several times with alcohol. The alcohol solutions were combined with the main solution, which was dried with potassium carbonate and evaporated under reduced pressure. The oily residue was dissolved in the minimum amount of absolute alcohol, and a large amount of absolute ether was added to the solution. The precipitate that formed was filtered off and washed with absolute ether, and the solution was again evaporated under reduced pressure. The viscous oil that remained rapidly crystallized. The precipitate was filtered off and washed with absolute ether. The product was 3 g of 3-amino-3-phenyl-1-propanol, m.p. 75-76° (needles from benzene). The literature [7] gives m.p. 73°.***

$C_{18}H_{19}O_9N_4$. Calculated %: N 14.74

2. Reduction of β-Amino-3,4-methylenedioxyhydrocinnamic Acid. In an atmosphere of nitrogen, 5.1 g of $LiAlH_4$ was added to 95 ml of cooled dry tetrahydrofuran with cooling and stirring, and 10 g of β-amino-3,4-methylenedioxyhydrocinnammic acid was then added slowly. The mixture was heated for six hours in a water bath. On the next day the reaction mixture was treated as in the preceding experiment. The product obtained after removal of solvents was 3.55 g (38%) of 3-amino-3-(3,4-methylenedioxyphenyl)-1-propanol, m.p. 52.5-55° (fine needles from absolute alcohol).

Found %: N 7.39; C 61.36; H 6.62
$C_{10}H_{13}O_3N$. Calculated %: N 7.18; C 61.54; H 6.67

When β-amino-3,4-methylenedioxyhydrocinnamic acid was reduced with $LiAlH_4$ in ether, a poorly crystallizing oil was obtained, and from this, by the action of ethereal hydrogen chloride, the hydrochloride of 3-amino-3-(3,4-methylenedioxyphenyl)-1-propanol, m.p. 176-178°, was obtained.

Found %: N 6.00
$C_{10}H_{14}O_3NCl$. Calculated %: N 6.05

The hydrochloride was reconverted into the base, and from this the picrate, m.p. 184-185°, was prepared.

Found %: N 13.63; C 45.62; H 3.84
$C_{16}H_{14}O_{10}N_4$. Calculated %: N 13.21; C 45.28; H 3.77

3. Reduction of 3-Aminononanoic Acid. In an atmosphere of nitrogen, 7 g of 70% $LiAlH_4$ was added gradually to 100 ml of strongly cooled stirred dry tetrahydrofuran, and 9 g of 3-aminononanoic acid was then added in small portions. The mixture was at first stirred at room temperature, and was then boiled for six hours in a water bath. On the next day the reaction mixture was treated as in Experiment 1. The residue after removal of solvents under reduced pressure was 7.8 g of a yellow oil, which was vacuum-distilled twice. The yield of 3-amino-1-nonanol was 7.0 g (80%), b.p. 120-121° (3 mm).

Found %: N 9.01; C 68.13; H 12.82
$C_9H_{21}ON$. Calculated %: N 8.81; C 67.92; H 13.21

When 3-amino-1-nonanol was allowed to stand in the air, its carbonate was formed, and this could be obtained also by passage of carbon dioxide through an ethereal solution of the amino alcohol; m.p. 89-92°.

Found %: N 7.40
$C_{19}H_{44}O_5N_2$. Calculated %: N 7.37

4. Reduction of β-Aminocyclohexanepropionic Acid. In an atmosphere of nitrogen, 1.5 g of 70% $LiAlH_4$ was added gradually with stirring and cooling to 30 ml of dry tetrahydrofurn, and 1.65 g of β-aminocyclohexanepropionic acid was then added. After six hours the mixture was cooled and treated in the usual way. Solvents were distilled off, and the residue was an oil. Extraction of this oil with a mixture of diethyl ether and petroleum ether gave 0.5 g of the carbonate of γ-aminocyclohexanepropanol, m.p. 127-129°.

Found %: N 7.49
$C_{19}H_{36}O_5N_2$. Calculated %: N 7.45

5. Reduction of 3-Aminobutyric Acid. In an atmosphere of nitrogen, 6.6 g of (70%) $LiAlH_4$ was added gradually with cooling and stirring to 135 ml of absolute ether, and 5 g of 3-aminobutyric acid was then added. The mixture was heated for six hours in a water bath, and then treated in the usual way. The ethereal-alcoholic solution was evaporated under reduced pressure, and the residue was 1.15 g (27%) of 3-amino-1-butanol, b.p. 81-82° (19 mm), which has been described previously [8]. It is probable that the yield could have been improved by carrying out the reaction in tetrahydrofuran. When an attempt was made to determine the melting point of the pure picrate in a block, an explosion occurred; the explosion temperature was 334°.

SUMMARY

Some β-amino acids were reduced to the corresponding amino alcohols with the aid of lithium aluminum hydride.

SOME REACTIONS OF β-AMINO-1-NAPHTHALENEPROPIONIC ACID AND β-METHYLAMINO-1-NAPHTHALENEPROPIONIC ACID

V. M. Rodionov * and L. V. Antik

In continuation of our investigations on the chemistry of β-amino-1-naphthalenepropionic acid and its derivatives [1, 2], we have synthesized N-alkoxycarbonyl and N-methyl derivatives of these compounds and studied some of their properties and reactions. We prepared the hydrazides of β-(methoxycarbonylamino)- and β-(ethoxycarbonylamino)-1-naphthalenepropionic acids. The former was submitted to the Curtius reaction, the azide so obtained being heated in dry benzene and converted into 1-(methoxycarbonyl)-5-(1-naphthyl)-2-imidazolidinone [3, 2], which was readily hydrolyzed to 4-(1-naphthyl)-2-imidazolidinone [2]:

Reaction of β-(methoxycarbonylamino)-1-naphthalenepropionamide with hypobromite at 80° gave the same 4-(1-naphthyl)-2-imidazolidone:

Reaction with hypobromite was therefore accompanied by elimination of the acyl residue.

By the method of Rodionov and Zvorykina [4], the corresponding β-(aminoureido) acid was synthesized from β-(methoxycarbonylamino)-1-naphthalenepropionic hydrazide:

Syntheses of β-methylamino-1-naphthalenepropionic acid was carried out under the following conditions:

1. Heating of 1-naphthaldehyde with malonic acid and methylamine in glacial acetic acid (yield 21.5%):

* Deceased.

2. Under the conditions described by Rodionov and Kurtev for 2-naphthaldehyde [5], namely, heating of 1-naphthaldehyde with malonic acid, methylamine hydrochloride, and anhydrous potassium acetate in glacial acetic acid (yield 37%).

3. From N-(1-naphthylmethylene) methylamine • by heating it with malonic acid:

a) in absolute alcohol (yield 17.2%) under the conditions described by Johnson [6] for the synthesis of β-methylamin.hydrocinnamic acid and by Rodionov and Kurtev [5] for the synthesis of β-methylamino-2-naphthalenepropionic acid;

b) in dry benzene (yield 34.2%) under the conditions used by Rodionov and Yavorskaya [7] for the preparation of β-methylaminohydrocinnamic acid.

In order to characterize β-methylamino-1-naphthalenepropionic acid, its ethyl ester, hydrazide, amide, N-benzoyl derivative, and N-nitroso compound were prepared.

EXPERIMENTAL

β-(Methoxycarbonylamino)-1-naphthalenepropionic Acid. Gradual addition was made of 8.3 ml of methyl chloroformate to a solution of 23.4 g of the hydrochloride of β-amino-1-naphthalenepropionic acid in 208 ml of 10% caustic potash at 2-5° with stirring. Stirring was continued at the same temperature for a further two hours, and the reaction mixture was then acidified with hydrochloric acid. The precipitate that formed was filtered off and washed with water. The product, amounting to 18.8 g (74%), melted at 181.5-183°. Recrystallization from water gave needles of m.p. 182.5-184°.

Found %: N 5.28
$C_{15}H_{15}O_4N$. Calculated %: N 5.05

Ethyl β-(Methoxycarbonylamino)-1-naphthalenepropionate. Dry hydrogen chloride was passed for 4-5 hours through a solution of 9 g of the methoxycarbonylamino acid in 65 ml of absolute alcohol at 60-70°, and the solution was then cooled to 0°, saturated with hydrogen chloride, and set aside overnight. Solvent was removed under reduced pressure, and the residue was treated with water and ether. The ether extract was washed with 5% sodium bicarbonate solution and then with water. When ether was removed, a rapidly solidifying oil remained. Crystallization from alcohol gave 7 g (70.5%) of needles melting at 91.5-93°.

Found %: N 4.68
$C_{17}H_{19}O_4N$. Calculated %: N 4.65

Ethyl β-(Ethoxycarbonylamino)-1-naphthalenepropionate. This was prepared from the ethoxycarbonylamino acid •• under the conditions for the preparation of the ethyl ester of the methoxycarbonylamino acid. The yield of ester, m.p. 43-48°, was 99.7%. It was recrystallized twice from alcohol (needles) and washed with ether; it then melted at 45-51°. The substance of m.p. 45-51° was used without further purification for the preparation of the hydrazide.

β-(Methoxycarbonylamino)-1-naphthalenepropionic Hydrazide. A solution of 7 g of ethyl β-(methoxycarbonylamino)-1-naphthalenepropionate and 3.5 g of hydrazine hydrate in 8 ml of absolute alcohol was boiled over a gauze for 20 minutes. To the thick crystalline mass that formed, 15 ml of absolute alcohol was added and the mixture was heated in a water bath for 1 hour 40 minutes. The precipitate was filtered off and washed with water and alcohol. The yield of hydrazide was 6.29 g (94.2%); m.p. 216-217° (needles from alcohol and plates from water).

• This compound was prepared under the conditions of the synthesis of the corresponding 2-naphthylmethylene compound [5].

•• β-(Ethoxycarbonylamino)-1-naphthalenepropionic acid was prepared by Rodionov and Kravchenko [1].

Found %: N 14.56

$C_{18}H_{17}O_3N_3$. Calculated %: N 14.63

β-(Ethoxycarbonylamino)-1-naphthalenepropionic Hydrazide. This was prepared under the conditions described for the hydrazide of the methoxycarbonylamino acid. Yield 92.9%; m.p. 219-21.1° (needles from alcohol).*

Found %: N 14.39

$C_{16}H_{15}O_2N_3$. Calculated %: N 13.95

β-(Methoxycarbonylamino)-1-naphthalenepropionyl Azide. Concentrated hydrochloric acid (8.25 ml) was added to a boiling suspension of 2 g of the hydrazide in water; the hydrazide dissolved. The solution was filtered and cooled at 0°; it was shaken while a solution of 0.5 g of sodium nitrite in 9 ml of water was added. There was an immediate precipitate, which was filtered off after a few minutes and washed on the filter with ice water. The yield of azide, which melted with decomposition at 41-43°, was 1.95 g (93.7%). When the reaction was carried out in acetic acid solution, the azide was contaminated with simultaneously formed diacylhydrazine, which is insoluble in hot alcohol. After recrystallization from acetic acid it melted at 268-269°.

Found %: N 10.20

$C_{30}H_{30}O_6N_4$. Calculated %: N 10.33

1-(Methoxycarbonyl)-5-(1-naphthyl)-2-imidazolidinone. A solution of 1.94 g of the azide in 50 ml of dry benzene was boiled in a water bath for five hours. Benzene was distilled off, and crystallization of the residue from alcohol gave 0.78 g (44.3%) of a substance of m.p. 191-193° (long rectangular plates).

Found %: N 10.15

$C_{15}H_{14}O_3N_2$. Calculated %: N 10.37

Hydrolysis of 1-(Methoxycarbonyl)-5-(1-naphthyl)-2-imidazolidinone. A suspension of 0.5 g of the (methoxycarbonyl) imidazolidinone in 25 ml of 15% caustic soda solution was boiled for five hours. The precipitate was filtered off and washed with water. Crystallization from alcohol gave 0.27 g (68.9%) of 4-(1-naphthyl)-2-imidazolidinone,** m.p. 220-221°.

β-(Methoxycarbonylamino)-1-naphthalenepropionamide. Sulfuryl choloride (8.72 g) was added to 8 g of the methoxycarbonylamino acid, cooling being applied by means of ice water. The mixture was then heated at 40° for 3-4 hours, and the excess of sulfuryl chloride was distilled off under reduced pressure. The acid chloride was dissolved in dry benzene, and dry ammonia was passed through the solution. The amide was precipitated and was filtered off and washed, first with 2-3% caustic soda solution, then with water, and finally with ether. Two recrystallizations from alcohol gave 5.92 g (74.2%) of amide, m.p. 238-239° (fine flat needles).

Found %: N 10.38

$C_{15}H_{16}O_3N_2$. Calculated %: N 10.29

Reaction of β-(Methoxycarbonylamino)-1-naphthalenepropionamide with Hypobromite. Hypobomite solution was prepared from 29.6 ml of 15% caustic soda solution and 3.5 g of bromine at −7°, and 2.5 g of the amide was added. The mixture was stirred at room temperature, and after 30 minutes the amide had completely dissolved and an oil had separated. After a further 30 minutes the mixture was gradually heated. At 60° the oil became thin, but at 80° it solidified. The mixture was kept for several minutes at 80°. When the mixture was cool, the precipitate was filtered off, washed with water, and recrystallized from alcohol. The

* The ethoxycarbonylamino and methoxycarbonylamino hydrazides are precipitated in the pure state directly from the reaction solutions.

** 4-(1-Naphthyl)-2-imidazolidinone has been prepared previously [2].

product (0.45 g) was found to be identical with 4-(1-naphthyl)-2-imidazolidinone.

β-(3-Aminourcido)-1-naphthalenepropionic Acid. A suspension of 0.6 g of β-(methoxycarbonylamino)-1-naphthalenepropionic hydrazide in 5 ml of 10% caustic potash solution was boiled until the hydrazide dissolved completely (10-15 minutes). The solution was cooled, filtered from a little suspended matter, and acidified with acetic acid. There was a precipitate of 0.43 g (90.4%) of white needles, m.p. 153-154° (from alcohol; clusters of thin plates).

Found %: N 15.41
$C_{14}H_{15}O_3N_3$. Calculated %: N 15.38

Hydrochloride of β-Methylamino-1-naphthalenepropionic Acid. A mixture of 15.6 g of 1-naphthaldehyde, 13 g of malonic acid, 10.1 g of methylamine hydrochloride, 15 g of anhydrous potassium acetate, and 50 ml of glacial acetic acid was heated in a water bath for nine hours; at the beginning of the heating the mixture frothed strongly. A thick crystalline mass was formed, and 60 ml of 7-8% hydrochloric acid was stirred in. The mixture was heated at 70-80° for ten minutes. The crystals present were filtered off, washed two or three times with 7-8% hydrochloric acid at 70-80°, and then washed with water. The yield of the 1-naphthaleneacrylic acid so obtained was 9.7 g (49%). The acid solution was evaporated down to 200-250 ml, and then cooled. The crystals of the hydrochloride of the amino acid which then came down were filtered off, dried, and washed with ether; yield 9.8 g (37%); m.p. 198.5-200° (long rectangular plates from absolute alcohol).

Found %: N 5.16
$C_{14}H_{16}O_2NCl$. Calculated %: N 5.27

β-Methylamino-1-naphthalenepropionic Acid. This was prepared by treating a thick suspension of its hydrochloride with saturated sodium acetate solution. The hydrochloride dissolved completely, and then a precipitate of the amino acid formed. It crystallized from alcohol in needles, m.p. 191-192°.

Found %: C 73.29; H 6.62; N 5.83
$C_{14}H_{15}O_2N$. Calculated %: C 73.31; H 6.60; N 6.11

Ethyl β-Methylamino-1-naphthalenepropionate. Absolute alcohol (50 ml) was added to 6 g of the hydrochloride of the methylamino acid, and dry hydrogen chloride was passed at 60-70° for 4-6 hours. The hydrochloride of the amino acid slowly dissolved, and another crystalline substance was simultaneously precipitated. The mixture was cooled, the precipitate was filtered off, and excess of solvent was distilled from the reaction solution under reduced pressure. The residue crystallized and was purified together with the crystals that appeared earlier by recrystallization from small amounts of absolute alcohol. After being washed with dry ether, the crystals melted at 145.5-146.5° (long hexagonal plates). The yield of ester was 5.51 g (about 83%).

Found %: N 4.67
$C_{18}H_{20}O_2NCl$. Calculated %: N 4.77

β-(N-Methylbenzamido)-1-naphthalenepropionic Acid. Benzoyl chloride (10.5 ml) was added at 20° over ten minutes to a stirred solution of 2 g of the hydrochloride of the methylamino acid in 17 ml of 10% caustic potash. The mixture was then kept at the same temperature for two hours. The precipitate obtained by acidification with hydrochloric acid was filtered off and carefully washed with boiling water; yield 2.15 g (85.7%); m.p. 173-174°. After recrystallization from alcohol the melting point was 175-177° (long octagonal prisms).

Found %: N 4.39
$C_{21}H_{19}O_3N$. Calculated %: N 4.20

β-(Methylnitrosamino)-1-naphthalenepropionic Acid. A solution of 0.34 g of sodium nitrite in 3.4 ml of water was added at 26° to a mixture of 1 g of the hydrochloride of the methylamino acid and 6.75 ml of 3% hydrochloric acid. The precipitate immediately dissolved, and a yellow viscous oily layer formed on the surface. After 30 minutes the mixture was heated to 35° and set aside overnight. The oily layer solidified. The yield of the nitroso compound, m.p. 125-128°, was 0.75 g (77.2%). When attempts were made to crystallize it from alcohol or aqueous alcohol, an emulsion was formed from which the product crystallized out after 1-2 days; m.p. 124-126° (prisms).

Found %: N 11.00
$C_{14}H_{14}O_3N_2$. Calculated %: N 10.85

β-Methylamino-1-naphthalenepropionic Hydrazide. The free base was liberated from 3.46 g of the hydrochloride of the ethyl ester of the methylamino acid by the action of 20% sodium carbonate solution. The product was extracted with ether from the emulsion then obtained, ether was removed, and the residue was dried in a desiccator. The oily free base and 1.73 ml of hydrazine hydrate were dissolved in 4.5 ml of absolute alcohol, and the solution was boiled for 5-6 hours. Alcohol and excess of hydrazine hydrate were distilled off under reduced pressure, and the residue was washed with ether and water. The product (2.6 g) was recrystallized from water or aqueous alcohol (needles), and after being dried at 80° and 10 mm for three hours it melted sharply at 113-114°.

Found %: N 17.63
$C_{14}H_{17}ON_3$. Calculated %: N 17.28

β-Methylamino-1-naphthalenepropionamide. The free base was liberated from 1.5 g of the hydrochloride of the ethyl ester of the methylamino acid (see preceding experiment) and was dissolved in 18 ml of absolute alcohol. The solution was saturated with dry ammonia. After three weeks the alcohol was distilled off, and the oil that remained was treated with ether. There was a precipitate, which was filtered off, washed with water and with ether, and recrystallized from water. Long hexagonal plates were obtained; m.p. 130-132°; yield 0.412 g (35.4%).

Found %: N 12.08
$C_{14}H_{15}ON_3$. Calculated %: N 12.28

SUMMARY

1. β-Methylamino-1-naphthalenepropionic acid and some of its derivatives were prepared.

2. The previously described β-amino-1-naphthalenepropionic acid was converted into 4-(1-naphthyl)-2-imidazolidinone by Hofmann's reaction—treatment of β-(methoxycarbonylamino)-1-naphthalenepropionamide with hypobromite—and by the Curtius reaction—heating of β-(methoxycarbonylamino)-1-naphthalenepropionyl azide in benzene. The primary product in the latter case was 1-(methoxycarbonyl)-5-(1-naphthyl)-2-imidazolidinone, which was obtained in high yield, and this was readily hydrolyzed to 4-(1-naphthyl)-2-imidazolidinone.

CHLORINATION OF ALKANES IN PRESENCE OF NITROGEN DIOXIDE

V. A. Nekrasova and N. I. Shuikin

In our previous investigations [1] the chlorination of alkanes was carried out at a molar ratio of hydrocarbon to chlorine of 10 : 1. Excess of hydrocarbon was found to be essential for the avoidance of explosions, which can occur under the conditions of vapor-phase chlorination. In order to utilize the unchanged hydrocarbons more fully, after separation from the chloro derivatives they were again chlorinated, a procedure that complicated the preparation of haloalkanes. In these investigations 1% of unsaturated hydrocarbons was added to the hydrocarbon as a chain initiator.

In the present investigation we carried out the chlorination of alkanes in presence of nitrogen dioxide (2%). The presence of this homogeneous catalyst was favorable to uniform reaction without explosions and enabled us to carry out vapor- and liquid-phase chlorination of C_6–C_{12} n-alkanes at a molar ratio of hydrocarbon to chlorine of 1 : 1 and a rate of passage of chlorine into the reaction zone of 1.2 liters per hour.

For the vapor-phase chlorination of hexane and heptane, comparatively high temperatures, 265-320°, were necessary; in the liquid phase the chlorination of these hydrocarbons was extremely slow. The optimum temperature for the chlorination of C_8–C_{12} alkanes rises only slightly with increase in molecular weight, and for these hydrocarbons both vapor-phase and liquid-phase chlorination are possible. The vapor-phase chlorination of dodecane and higher hydrocarbons is difficult, for a high temperatures the chloro compounds formed are partially decomposed with separation of carbon and formation of gases.

EXPERIMENTAL

Our raw material for the preparation of chloro derivatives of alkanes was a straight-run gasoline derived from Crimean petroleum. The normal hydrocarbons were separated from isomers and cyclic hydrocarbons by means of the urea complex [2]. They were then subjected to precise rectification through a 70-plate column. The hydrocarbons isolated had the properties shown in Table 1.

Undecane and dodecane were separated from the ligroin fraction of Crimean petroleum via the urea complexes; they had the following properties—undecane: b.p. 195-196° (757 mm), d_4^{20} 0.7403, and n_D^{20} 1.4172 dodecane: b.p. 215.5-217° (755 mm), d_4^{20} 0.7489 and n_D^{20} 1.4218.

The vapor-phase thermal chlorination of C_6–C_{12} alkanes was carried out in the apparatus described in a previous paper [3]. For the rather volatile hydrocarbons (C_6 and C_7), the lengths of the tubes of the coil reactor may be increased to two or more meters.

By the way of example we shall describe briefly the results of the separation of the products of the vapor-phase chlorination of dodecane. The chlorination of 85 g of dodecane was carried out at 400° at the molar ratio of hydrocarbon to chlorine and the rate of introduction of chlorine indicated above. Fractionation of the chlorination product (83 g) gave the following fractions:

Fraction I, b.p. 243–245° (578 mm); 37.0 g (44.6%); n_D^{20} 1.4380; d_4^{20} 0.8614; Cl 17.29%

Fraction II, b.p. 255–257° (758 mm); 23.7 g (28.5%); n_D^{20} 1.4425; d_4^{20} 0.8670; Cl 17.28%; Found MR 62.47; Calculated for $C_{12}H_{25}Cl$ MR 62.48

Fraction III, b.p. 257–259°; 17.4 g (21%)

Residue 4.9 g (5.9%).

On the basis of a comparison of its constants with data in the literature [4], Fraction 1 was taken to be secondary monochloro compounds. Fraction 2 corresponded to 1-chlorodecane, and Fraction 3 to mixture of dichloro derivatives. The results of experiments carried out under optimum conditions are given in Table 2.

TABLE 1

Properties of n-Alkanes Isolated from Crimean Gasoline

Hydrocarbon	B.p. in °C (p in mm)	n_D^{20}	d_4^{20}
Hexane	68—69 (751)	1.3750	0.6594
Heptane	98—99 (754)	1.3878	0.6838
Octane	125—126 (754)	1.3975	0.7026
Nonane	150—151 (751)	1.4054	0.7177
Decane	174—175 (750)	1.4120	0.7298

It follows from Table 2 that under the given conditions, the highest yields of primary chloro compounds are obtained in the chlorination of octane, nonane, and decane when the temperature is in the range 365-385°. The chloro compounds obtained were washed with sodium carbonate solution and with water, dried with anhydrous calcium chloride, and subjected to precise rectification. The properties of the monochloro derivatives are given in Table 3.

The values obtained for the constants of the primary monochloro compounds are in accord with data in the literature [4].

The liquid-phase chlorination of C_5-C_{12} alkanes was also carried out. It was found that hexane at 66° and heptane at 95° are chlorinated with formation of 67-71% of chloro derivatives, mainly monochloro compounds. The chlorination results are given in Table 4.

TABLE 2

Vapor-Phase Chlorination of Alkanes in Presence of Nitrogen Dioxide

Original alkane	Chlorination temperature °C	Yield of chloro derivative (% on the hydrocarbon that reacted)			
		Primary monochloro	Secondary monochloro	Dichloro	Residue and losses
Hexane	285	50.0	15.6	28.6	5.8
Heptane	320	50.5	16.0	29.0	4.5
Octane	365	60.5	23.5	14.0	2.0

Dodecane	213	14.3	60.0	22.5	3.2

A comparison of Tables 2 and 4 shows that liquid-phase chlorination results in the formation mainly of secondary chloro compounds, whereas chlorination in the vapor phase gives mainly primary monochloro compounds. The process of introducing chlorine atoms formed by the thermal dissociation of Cl_2 [5] into the molecule of a saturated hydrocarbon is a chain reaction, and the presence of a small amount (2%) of nitrogen dioxide facilitates the formation of the free radical [3].

SUMMARY

1. A study was made of the reaction of chlorine with C_6–C_{12} n-alkanes in presence of nitrogen dioxide in the vapor and liquid phases.

2. Optimum conditions for the synthesis of primary and secondary chloro compounds were found.

RELATIVE ACTIVITIES OF NICKEL, ZINC, AND CHROMIUM OXIDES, SULFIDES, AND SELENIDES IN THE CATALYTIC DECOMPOSITION OF ISOPROPYL ALCOHOL

A. M. Rubinshtein, S. G. Kulikov*, and B. A. Zakharov

It is known that in some catalytic organic reactions nickel sulfide exhibits very satisfactory activity and high selectivity. There are many patents relating to this catalyst, and there are also some papers on its properties and field of application. The most important of these papers have been treated in a general review [1]. Selenides and tellurides have received very little study, being considerably less accessible than sulfides. From the point of view of the principle of structural correspondence developed in the multiplet theory of catalysis, it was of interest to obtain data characterizing the comparative activities of oxides, sulfides, selenides, and tellurides of nickel and some other metals under the same conditions in the same reactions, and to investigate their structural properties and phase composition. This was the object of the present investigation, and we selected nickel, zinc, nickel-zinc, and chromium catalysts for study. Unfortunately, we did not succeed in preparing the tellurides of these metals in a form suitable for catalysis. We prepared the catalysts and studied their activities in the following reactions: 1) decomposition of isopropyl alcohol; 2) selective hydrogenation of 1,3-butadiene to butene; and 3) reduction of nitrobenzene to aniline. In this paper we give the results of the work with isopropyl alcohol, and the next paper is devoted to a description of the other two reactions.

The group of catalysts selected for investigation are of interest also in connection with the allotropy (polymorphism) of some of the compounds present. The importance of investigating such substances and their phase transformations was pointed out by one of us in a review article, in which the question of the structural correspondence between reactant and catalyst was examined [2].

EXPERIMENTAL

The methods of preparing oxide and many sulfide catalysts are given in fair detail in the literature. For the preparation of selenides and tellurides the following methods can be used: Method A- The preparation of, for example, NiSe [3] and ZnTe [4] by direct combination of the elements at high temperature in an inert atmosphere. These reactions are highly exothermic, and considerable sintering with formation of a coarsely dispersed system is therefore inevitable. It follows that such a method for preparing a catalyst is unsuitable, and in fact the zinc telluride that we prepared in this way was quite inactive. Method B- Reduction of salts of the appropriate acids, e.g. $ZnSeO_3$, $NiSeO_3$, etc. [5], obtained by double decomposition with the sodium salts (Na_2SeO_3). Method C- Action of hydrogen selenide or telluride or its sodium salt on a salt of the appropriate metal (in particular ZnSe [6, 7], $NiTe_2$ [8], and chromium selenide [9] have been prepared in this way). Methods B and C have similar defects: a great tendency for contamination with compounds contained in the mother liquor, and the danger that the desired compounds will be hydrolyzed during the washing of the precipitates. Method D is the most convenient—the direct action of hydrogen selenide or telluride on the oxide or hydroxide of the appropriate metal. In this method the only volatile reaction product—the water formed—is readily removed from the reaction zone by the gas that is passing (H_2Se+N_2), and hydrolysis products, if formed, will again enter the reaction. This method, which has been described in detail for the preparation of nickel sulfide [1] and which permits the use of ready prepared oxide catalysts and of hydroxides (washed completely free from soluble salts), was the one that we used in the present work. For our purpose, this method had the further advantage that there was a genetic relationship in each series of O-, S-, and Se-catalysts and differences in content of impurities were kept to a minimum.

* Deceased.

NiO, ZnO, Cr_2O_3, and NiO-ZnO (25 mole-% NiO) were prepared from 10% solutions of the nitrates, which were precipitated at 65° with 10% solutions of KOH (Ni, Zn) and NH_3 (Cr_2O_3 and Ni-Zn). The hydroxides were washed until free from nitrate ions (diphenylamine as indicator), and were then formed into shape and dried at 120°. Part of each hydroxide was calcined in the air at 450° for seven hours, and part was set aside for conversion into sulfide and selenide.

The sulfide catalysts were prepared from the hydroxides (formed and dried at 120°) by passing hydrogen sulfide directly into the catalysis tube at 110-120° in the case of the nickel and mixed nickel-zinc catalysts and at 120-140° in the case of the zinc and chromium catalysts. Passage of a mixture of hydrogen sulfide and nitrogen was continued for some time after reaction was complete in order to facilitate the removal of water vapor, and the catalysts were cooled in this atmosphere. The catalysts did not smell of hydrogen sulfide. The preliminary heating of these, and also of the selenide catalysts, was carried out at the temperature of the experiment, and not at 450°, as in the case of the oxides.

The selenide catalysts were prepared similarly. Hydrogen selenide was prepared by passing electrolytic hydrogen, freed from oxygen, through molten selenium at 400° (in a quartz test tube). The gas passed over the hydroxide was therefore a mixture of hydrogen selenide and hydrogen. In other respects, the preparation of the catalysts was similar to that of the sulfides.

The specific surfaces of the catalysts were determined both before and after each series of experiments with the given catalyst. The determinations were based on adsorption isotherms for benzene vapor at 20°, which were measured in an apparatus incorporating a quartz spring balance, the surfaces of the samples being first cleaned by exposure at 200-300° to a high vacuum until constant weight was attained. The results are given in Table 1 together with X-ray phase analysis data, which were obtained with series-K_α chromium radiation, a vanadium filter being used for the removal of β-radiation.

The phase analysis was carried out by comparing the values found for the interplanar spacings and the intensities of the corresponding lines with the values for the pure substances (possible components of the catalysts) given in the literature. For NiO, $Ni(OH)_2$, ZnO, α- and β-ZnS, and Cr_2O_3, use was made of tabular data on standard X-ray diagrams [10]. For the remaining compounds the data were taken from their original sources: NiS [11-13], Ni_3S_2 [14], NiSe [13, 15-17], ZnSe [18], CrS and CrSe [15]. As will be seen from Table 1, in some cases the phase composition of the catalyst had changed after the experiment; moreover, some of the catalysts, even in their original state, were polyphase systems.

The experiments were carried out with isopropyl alcohol (fraction 81.5-82°) that had been rendered absolute by treatment first with calcium oxide, and then with metallic calcium. Of the two possible ways in which it could decompose, dehydrogenation was followed by measuring the volume of hydrogen formed, and dehydration by measuring the volume of propene (STP). The conditions in the preparatory stage of the experiment—the time required to raise the temperature to the required value, the time required to check the constancy of this temperature, the amount of decomposition products of isopropyl alcohol required to remove foreign gas from the system—were kept standard in all cases. The experiments were carried out in the usual continuous catalysis system, the temperature being measured by the aid of a thermocouple placed at the center of the catalyst layer. Liquid reaction products and unchanged alcohol were separated in a receiver fitted with reflux condenser, and gaseous products were collected above saturated brine in a constant-level receiver and were analyzed for carbon dioxide, carbon monoxide, propene, hydrogen, and saturated hydrocarbons. As carbon monoxide was formed only in a few experiments and only in very small amounts (not more than 1.3 ml per milliliter of alcohol passed), we have not included the relevant data in Table 2.

In all experiments the volume of catalyst was 10 ml and its grain size was 1.5 x 3 mm; isopropyl alcohol was passed at a space velocity of 0.6×0.02 hour^{-1}. The experimental results are given in Table 2 in the form: a) of degrees of conversion, characterized by the volumes (STP) of the components of the gas mixture formed from 1 ml of alcohol *, and b) of specific activities—the volumes (ml) of hydrogen and propene formed in the passage of 1 ml of alcohol over 1 g of catalyst. The variation of catalyst activity with temperature is shown in Figures 1-4. During each individual experiment the rate of decomposition of the alcohol was constant. As stated above, some catalysts changed in composition during the experiments: this was shown by

* As the volume of catalyst was 10 ml, the specific activities per unit volume were 0.1 of these values.

• A question mark indicates that the presence of the phase has not been established with certainty.

phase-composition determinations after each series of experiments with a particular catalyst. Owing to this change in composition, in experiments with NiSe—even at 245°—the end of the catalysis tube and the walls of the receiver were very quickly covered with a red deposit of elementary selenium. A similar phenomenon was observed also for ZnSe. When sulfide catalysts were used, the water in the receiver for gaseous products gradually became turbid (opalescent) owing to the appearance of elementary sulfur. These visible changes were in accord with the results of phase analysis (Table 1).

Discussion of Experimental Results

It may be expected that the following phases may be present in the catalysts investigated: hexagonal ZnO (wurtzite type: a = 3.22 A; c = 5.16 A; c/a = 1.61) and α-ZnS (wurtzite: a = 3.84 A; c = 6.28 A; c/a = 1.64); face-centered cubic β-ZnS (sphalerite: a = 5.34 A), ZnSe (a= 5.66 A), and NiO (a= 4.17 A); amorphous α-NiS, hexagonal β-NiS (a = 3.24; A; c = 5.30 A, c/a = 1.55), being the most stable form of nickel sulfide, and rhombohedral γ-NiS (a = 9.61 A; c = 3.45; c/a = 0.32). Nickel sulfides undergo the phase transformations $\alpha \rightarrow \gamma \rightarrow \alpha\beta$, which occur spontaneously at moderate temperatures. There is the further possibility of the presence in the catalysts of nickel subsulfide Ni_3S_2, the rhombohedral lattice of which differs very little from a cubic lattice a = 4.04 A; α = 90.3°). There are also the nickel selenides [13], which are isomorphous with the sulfides: γ-NiSe (a = 9.84 A; c = 3.18 A; c/a = 0.32) and β-NiSe (a = 3.66 A; c = 5.33 A; c/a = 1.46). Possible chromium compounds are the rhombohedral oxide (a = 5.35 A; α= 54°58'), the hexagonal sulfide (a = 3.44 A; c = 5.67 A; c/a = 1.65), and the selenide (a = 3.59 A; c = 5.80 A; c/a = 1.62). The formation of hydroxides cannot be excluded, and in the case of nickel catalysts reduction to the metal may occur. As will be seen from Table 1, many of the catalysts are polyphase systems even before the experiments. We will indicate the most important cases of changes in phase composition occurring during the experiments with the catalysts. We must first point out the appearance of crystalline phases in the originally amorphous catalyst No. 11 (Table 1), which can be explained by the reorientation of particles at the temperature of the experiments; the increase in the surface area of this catalyst must be attributed to the formation of new phases, ZnO and NiO, during the experiments. Again, in the nickel sulfide catalyst No. 2, the γ-NiS phase disappeared during the experiments owing to transformation into β-NiS, and the subsulfide Ni_3S_2 made its appearance; as will be seen from Fig. 1, these changes in phase composition were accompanied by change of activity in the alcohol-decomposition reaction.

TABLE 2

Experimental Results

Catalyst	Temperature (°C)	Amount of gas formed from 1 ml of alcohol (STP)					Specific Activity

In a number of cases (catalysts No. 2, 9, 12) oxides were detected in the catalysts after the experiments, these being probably formed by the hydrolysis of sulfides and selenides. Some metallic nickel was found in catalyst No. 1 after the whole series of experiments had been carried out over it. It must be emphasized that in these cases the phase transformations occurred throughout the mass, since the compounds concerned were detected by X-ray structure analysis. In view of this, it may be assumed that similar chemical changes in the catalysts occurred also in other cases, but were localized on the surface, the concentrations of the new phases being insignificant.

Phase analysis showed, therefore, that the investigated sulfide and selenide catalysts are systems of low stability, which undergo appreciable change under the conditions of the alcohol-decomposition reaction. Table 1 shows also that catalysts No. 2, 3, 6, 7, 8, and 9 had high bulk densities. In the original state, catalysts No. 2 and 6 had very low specific surfaces. Sintering during use was greatest for catalyst No. 8, the specific surface of which fell from 190 to 83 sq. m/g. The specific surface of NiO increased during the experiments, owing, apparently, to the appearance of the new phase $Ni(OH)_2$; the same occurred with ZnSe, owing to partial formation of ZnO, and with NiS-ZnS, for which the phase composition in the original catalyst is unknown, since it was amorphous to X-rays. In the remaining cases the change in specific surface during the experiments was insignificant.

Figures 1-4 represent the variation of overall specific activity with temperature (cf. Table 2; the separate specific activities for the two reactions can be readily determined from these data and the data in Table 3). In our experiments the specific activity diminished in the series O > S > Se, in spite of the fact that NiS had a lower specific surface than the oxide and selenide, the specific surfaces of which were almost the same. At 245° the zinc catalysts were inactive, at 295° their activities were in accordance with the series Se > O ≈ S, and at 340° the series was S > O > Se, the selenide having a negligibly low specific surface. Incidently, our crystalline zinc sulfide catalyst differed in activity and phase composition from the similar catalyst prepared by the wet method [19]; in particular, it differed in phase composition after the experiments. For the chromium catalysts the activity series was Se > S > O at 245° and 195°, changing at 345° to Se > S ≈ O; it must be mentioned that the specific surface of the selenide was 50% higher than that of the oxide. The mixed Ni-Zn catalysts gave the same activity series as the nickel catalysts (O > S > Se), from which it follows that the properties of these catalysts are determined more by the nickel compounds than by the zinc compounds.

Fig. 1

Fig. 2

As a second characteristic of the catalysts, in Table 3 we give selectivity coefficients, $\frac{H_2}{H_2 + C_2H_6}$, i.e. the contribution made by dehydrogenation in the overall reaction. It will be seen that, whereas the mixed oxide catalyst No. 10 was exclusively dehydrogenating, the sulfide and selenide catalysts No. 11 and 12 were exclusively dehydrating. Similarly, nickel sulfide differed greatly in selectivity from the oxide and selenide: the last two catalysts were mainly dehydrogenating, and the sulfide was almost entirely dehydrating. There was an almost equally sharp difference between zinc selenide and oxide, on the one hand, and the sulfide, on the other. It is difficult to imagine that this difference in the sulfides was the result of the replacement of O in corresponding compounds by S or Se, for all these nonmetals belong to the same group of the periodic system and form compounds having similar chemical properties with the metals investigated—in some cases they even form isomorphous compounds. The great difference in selectivity in the cases described must rather be attributed to the liberation of hydrogen sulfide during the changes in phase composition of the catalysts (formation of Ni_3S_2 from NiS and ZnO from ZnS; see Table 1, phase composition after experiments). The hydrogen sulfide evolved is apparently in an active state and—being an acid, i.e. a catalyst for dehydration by the ionic mechanism—changes the ratio of the rates of the simultaneous reactions in favor of dehydration (the effect of adsorbed acids on selectivity is described in the paper [20]. A similar explanation serves for the selectivity of NiS-ZnS and NiSe-ZnSe. For the chromium catalysts, however, such an explanation is inadequate, for it is not confirmed by the change in phase composition, which could not be determined owing to the amorphous structures of the selenide and sulfide during the experiments, and, moreover, the selectivity coefficient varies regularly throughout the series, diminishing in the order O > S > Se at all experimental temperatures. Also, there is a great difference between the selectivities

TABLE 3

Selectivity Coefficients of Catalysts

Temperature	Ni			Zn			Ni – Zn			Cr		
	O	S	Se	O	S	Se	O	S	Se	O	S	Se
245	1	0.02	—	—	—	—	1.0	0	—	—	0.38	0.03
295	0.99	0.015	0.69	0.97	0.27	0.95	1.0	0	0.02	0.63	0.38	0.03
340	0.96	0.006	0.00	0.95	0.26	0.93	0.98	0	0.01	0.50	0.26	0.06

of sulfide and selenide, the selenide being more dehydrating than the sulfide, which was not observed in the cases described above. We consider that the observed differences in the selectivities of chromium catalysts, and also to some extent in the other catalysts discussed above, are associated with differences in the interatomic distances in the lattices of the O, S and Se compounds and with the distribution of alcohol molecules on these lattices—i.e. with the structural factor. We will return to this question in our next paper, which is devoted to hydrogenation reactions on the same catalysts.

Fig. 3

Fig. 4

In discussing the causes of the variation in the selectivity of sulfides, and in some cases also selenides, we must take account of the possible effect of hydrogen sulfide (or selenide) adsorbed during the conversion of the hydroxide into sulfide or selenide. As the catalysts were odorless, the amounts of hydrogen sulfide adsorbed on them were undoubtedly small. During the heating of the catalysts to the temperature of the experiments and during the passage of alcohol, hydrogen sulfide must have been rapidly displaced from the surface. Adsorbed hydrogen sulfide, therefore, could act for only a short time at the beginning of an experiment, and not through the whole series. On the other hand, hydrogen sulfide formed in the above-described phase transformations is evolved over a long period. It is for this reason that we consider that, in the cases discussed above, processes associated with change in phase composition form the basis of one of the main causes of change in selectivity.

In conclusion, we will compare activities in each group—oxides, sulfides, and selenides—of the catalysts investigated. At 245° and 295° the most active oxide catalysts are NiO-ZnO and NiO, and at 340° decomposition of the alcohol occurs at about the same rate over all of the oxides investigated. At 245° all of the sulfides are of low activity, and ZnS is completely inactive; rise in temperature to 295° results in a great rise in activity, which is in the order NiS—ZnS > NiS > Cr_2S_3 > ZnS; and further rise in temperature to 340° causes the activities of the last two to be increased and those of the first two to be diminished. Of the selenides investigated, the most active were those of chromium and zinc; the mixed catalyst was of lower activity, and the activity of nickel selenide was very low.

SUMMARY

1. Data were obtained on the activites of oxides, sulfides, and selenides of nickel, zinc, and chromium and of the corresponding mixed Ni-Zn catalysts in the decomposition reaction of absolute isopropyl alcohol.

The changes in the phase compositions of these catalysts were determined, and their specific surfaces were measured under the conditions of the experiments.

2. It was shown that, under the conditions of the alcohol-decomposition reaction, sulfide and selenide and selenide catalysts are unstable systems. Thus, NiS undergoes a phase transformation into Ni_3S_2 with evolution of hydrogen sulfide, and ZnS undergoes a phase transformation into ZnO (hydrolysis).

3. It was found that the evolution of hydrogen sulfide or selenide which accompanies the phase transformations results in a great change in the selectivity of the catalysts (instead of dehydrogenating, they become dehydrating). Also, the variation in selectivity among metal oxides, sulfides, and selenides depends also on the interatomic distances in the crystal lattices of these substances, this being particularly evident in the chromium catalysts.

4. With respect to their activities in the decomposition of absolute isopropyl alcohol, metal oxides, sulfides, and selenides may be arranged in the following series: NiO > NiS > NiSe; ZnS > ZnO > ZnSe (340); CrS > CrSe > Cr_2O_3. The mixed Ni-Zn catalysts form the same activity series as the nickel catalysts.

ACTIVITIES OF NICKEL, ZINC, AND CHROMIUM OXIDES, SULFIDES, AND SELENIDES IN THE REDUCTION OF NITROBENZENE AND THE SELECTIVE HYDROGENATION OF A DIOLEFIN INTO AN OLEFIN

A. M. Rubinshtein, A. A. Dulov, S. G. Kulikov*, and N. A. Pribytkova

In the preceding paper [1] we gave the results of an investigation into the action of nickel, chromium, and mixed zinc-nickel oxides, sulfides, and selenides as catalysts for the decomposition of absolute isopropyl alcohol, and we described the preparation of these catalysts, their physical properties, and their phase compositions. Our study of the activities of these catalysts has been extended also to the selective hydrogenation of one double bond of a diolefin ($C_4H_6 + H_2 \longrightarrow C_4H_8$) and to the vapor-phase reduction of nitrobenzene to aniline ($C_6H_5NO_2 + 3H_2 \longrightarrow C_6H_5NH_2 + 2H_2O$). The present paper is devoted to a description of this investigation and a discussion of the results together with data obtained on the decomposition of isopropyl alcohol.

EXPERIMENTAL

From reported data on nickel sulfide catalysts [2] it is known that the hydrogenation and reduction reactions that we have selected proceed readily under high pressures and can be brought about also at ordinary pressure. Hence, in carrying out the experiments at ordinary pressure, we employed low space velocities of reactants over the catalyst so as to ensure an adequate degree of conversion. The experiments were carried out over separate, fresh portions of the catalysts described and characterized in the previous paper [1]. Determinations of the phase compositions of the catalysts by the X-ray structure method both after the hydrogenation and after the reduction reactions gave the same results for all the catalysts, except NiO and chromium selenide, as those obtained after the decomposition of isopropyl alcohol over these catalysts. The phase compositions of NiO catalysts after hydrogenation or reduction reactions in the present investigation differed from before in that no $Ni(OH)_2$ and metallic nickel crystalline phases were detected. After the experiments on the hydrogenation of butadiene, the crystalline phases Cr_2O_3 and CrSe were detected, although the original catalyst and catalysts used in the decomposition of the alcohol and in the reduction of nitrobenzene were amorphous to X-rays.

Catalytic Reduction of Nitrobenzene

All the catalysts were subjected to identical conditions. The catalyst (5 ml) was placed in a V-shaped quartz reactor [3]. This was heated in a vertical block electric furnace, the temperature of which was controlled with an electronic regulator. Nitrobenzene was passed through at a uniform rate of 0.04 liter per minute (space velocity 0.24 $hour^{-1}$; it was supplied through a calibrated automatic dosimeter), and hydrogen, purified from traces of moisture and oxygen, was passed in at the rate of 15 ml (STP) per minute, i.e. 11-12 mole-% excess. Each catalyst was investigated at three temperatures— 220°, 260°, and 300°—after which a control experiment was carried out at 260°. In some cases supplementary experiments were carried out in intermediate regions, and even (in the case of ZnO) at higher temperatures. The temperature in the center of the layer of catalyst was measured by means of a thermocouple.

*Deceased.

TABLE 1

Degree of Conversion of Nitrobenzene into Aniline*

Temperature (°C)	Degree of conversion (%)								
	NiO	NiS	NiSe	NiO — ZnO	NiS — ZnS	NiSe — ZnSe	Cr_2O_3	CrS	CrSe

* See note to Table 1 regarding zinc compounds.

The aniline content of the reaction product was determined by titrating the acidified catalyzate with sodium nitrite solution [4]. The activities of the catalysts were estimated from the extent of the conversion of nitrobenzene into aniline (Table 1), and were expressed also in the form of specific activity [degree of conversion (%) per gram of catalyst, Table 2]. The specific activity per unit volume can be found from the data in Table 1 by division by 5 (volume of catalyst in milliliters).

In an examination of Tables 1 and 2 the good reproducibility of the results on chromium catalysts should be noted. The repeat experiment at 260° was carried out after the 300° experiment. Satisfactory reproducibility was generally observed for mixed Ni-Zn and NiO catalysts, but it was poor for NiS and NiSe (lower activity in the repeat experiment), probably owing to the change in phase composition in these catalysts [1].

The experimental results show that the metal compounds contained in the catalysts can be placed in the following series of diminishing activity: Ni > Cr > Zn. The variation of specific activity with temperature is represented in Fig. 1 (a, b, and c) for all except the zinc catalysts. In the mixed catalysts, the addition of zinc compounds to nickel compounds results in appreciable diminution in activity, as compared with straight nickel catalysts: under the given conditions zinc compounds act as inert carriers.

Fig. 1. Dependence of the specific activities of the catalysts on temperature: a) nickel catalysts; b) nickel-zinc catalysts; c) chromium catalysts; □) oxides; △) sulfides; □) selenides; the black points refer to repeat experiments).

The nickel compounds fall in the following series in order of diminishing activity: S > Se > O. It is here important to note that the specific surface of NiS (6.4 sq.m/g) was considerably less than those of NiO (24 sq.m/g). and NiSe (27 sq.m/g). The curves for the change of activity with temperature show that nickel selenide and sulfide become less active with rise in temperature, whereas NiO becomes much more active (probably owing to partial reduction to metallic nickel on the surface, though this could not be observed as a crystalline phase). The reduction in the activities of sulfide and selenide may be due to two causes: 1) their partial oxidation by nitrobenzene—which the comparatively low excess of hydrogen in the system may not be able to prevent—with formation of oxide or sulfide; 2) transformation of NiS and NiSe into Ni_3S_2 and Ni_3Se_2.

Mixed Ni-Zn catalysts form the same activity series as the straight nickel catalysts. Chromium catalysts form the activity series Se > S ≈ O, and their specific surfaces were 38, 190, and 25 sq.m/g respectively. Nevertheless, the sulfide and oxide were approximately equally active, and less active than the selenide.

Selective Hydrogenation of Butadiene to Butene

A gas mixture consisting of 75% of electrolytic hydrogen and 25% of butadiene was passed from a gas meter to a drying column filled with solid caustic soda, and then to a reactor containing 5 ml of catalyst, which was placed in a vertical block electric furnace, the temperature of which was controlled by means of a contact galvanometer. The experiments were carried out in the temperature range 200-300° for 1-2 hours at space velocities of 5 and 10 hour^{-1}. The gaseous reaction products were collected in a calibrated gas holder over saturated brine. Gas volumes were reduced to STP. The amounts of butadiene in the original mixture and in the gaseous products was determined, accurate within 0.5%, in a Bushmarin apparatus (absorption with maleic anhydride). The amounts of diolefins and olefins in the gaseous products were determined also by absorption with mercuric sulfate solution. Butane was determined by combustion over copper oxide in a GIAP (State Institute of the Nitrogen Industry) apparatus. The degree of conversion of the butadiene was calculated from the difference between the amount of butadiene passed in and the amount that remained unchanged. The experimental results are given in Table 3.

It must be pointed out that at 250° NiO gave appreciable conversion of butadiene into butane, whereas at 225° butane was not formed in appreciable amounts and hydrogenation proceeded selectively with formation of butene. Three successive experiments with one sample of NiS at 250° showed that the activity of the catalyst changed considerably with time: the degree of conversion diminished from 88% in the first experiment to 57% in the third. Comparison of this result with the change in phase composition of the catalyst enables us to infer that the reduction in activity is associated with the accumulation of Ni_3S_2 in the catalyst.

* The reaction product contained 60 ml of butane, which corresponds to 25% of the original butadiene.

As in the reduction of nitrobenzene, in the hydrogenation of the double bond zinc catalysts were of very low activity. Chromium catalysts were highly active. Comparison of results obtained at space velocities of 5 and 10 hour^{-1} shows that this increase in space velocity has little effect on the degree of conversion for CrSe (250°), NiO (200°), NiS (250°), and NiSe (250°). With respect to specific activity in the hydrogenation of butadiene to butene, the metal oxides, sulfides, and selenides fall in the series Ni > Cr > Zn, i.e. their behavior is similar to that found in the reduction of nitrobenzene and in the decomposition of isopropyl alcohol [1]. With respect to specific activity in the hydrogenation of butadiene (Table 3), the nickel compounds fall in the series NiS > NiSe > NiO (with the exception of NiO at one temperature (250°), at which hydrogen was no longer selective and resulted in the formation of much butane).

The mixed Ni-Zn sulfide catalyst was also more active then the selenide: the activities of these catalysts are clearly determined by the nickel compounds. Chromium selenide was more active than the sulfide, which is particularly evident from their specific activities at 250° at a space velocity of 10 hour^{-1}.

Discussion of Results

The activities of the investigated catalysts in the reduction of nitrobenzene and the hydrogenation of a diolefin have been compared above, and for the decomposition of isopropyl alcohol this comparison was done in the preceding paper [1]. It must be emphasized that, as the phase compositions of the catalysts changed in the course of the experiments, we were cautious in our approach to an estimate of comparative activities, basing our views mainly on initial activities, as being more reliable: in the first short experiments phase transformations could not proceed very far and have any considerable effect. It should be noted that in all of our experiments there was a reduction in activity as we passed from compounds of Group VIII metals to those of Group II metals, and the sequence for the oxide, sulfide, and selenide of each metal was the same in the hydrogenation and reduction reactions. Some exceptions found for the decomposition of an alcohol [1] were apparently attributable to the fact that in this case reactions of a different type were occurring, namely, dehydration and dehydrogenation.

Fig. 2. Elementary cells: a) sphalerite; b) wurtzite; c) nickel arsenide.

For the correlation of activity with catalyst structure it is important to note that the sulfides and selenides that we have investigated have coordinated structures with homeopolar (α- and β-ZnS) or metallic bonds (NiS, NiSe, and others). In crystals of sphalerite (Fig. 2 a) and wurtzite (Fig. 2 b) the coordination of Zn with respect to S and of Se with respect to Zn is quaternary. Nickel and chromium sulfides and selenides belong to the nickel arsenide type (Fig. 2 c) with coordination numbers of the metal atom with respect to S (or Se) and of S (or Se) with respect to the metal atom of 6 [5].

As in each of the series of compounds investigated the metal remains the same, it was natural to compare the activities with the covalent radii of the nonmetals (O–0.66; S–1.04; Se–1.17 A [5]), the covalent radius of the metal being regarded as constant. This has been done in Fig. 3 for the reduction of nitrobenzene over nickel and chromium catalysts. We may point out that, although the extent of conversion is not great, the activity sequence of oxide, sulfide, and selenide cannot be fortuitous, for it is preserved at all temperatures and, moreover, is identical for nickel and mixed Ni-Zn catalysts. In the series of nickel compounds, the sulfide was most active, whereas in the chromium series the selenide was most active—although it might be supposed that the variation in activity should be the same in both series. This contradiction, however, is only apparent: bivalent nickel bound with six electron pairs at the corners of a tetrahedron has a covalent atomic radius of 1.39 A [6], whereas under similar circumstances chromium has a covalent atomic radius of 1.22 A (extrapolation of data from [7] to a coordination number of 6). Hence, in the compounds under consideration the atomic radius of Ni is greater than that of Cr by 0.17 A, which is very little different from the amount by which the covalent radius of Se is greater than that of S.

Thus, the differences between the radii of the metals and the radii of the nonmetals are mutually compensating, and the Ni-S distance in the NiS lattice is equal to the Cr-Se distance in the chromium selenide lattice. Hence, in each of the series of compounds represented in Fig. 3, the highest activity is possessed by a compound having a given M-X interatomic distance, namely 2.40-2.43 A, which gives striking confirmation of the principle of structural correspondence in the multiplet theory of catalysis [8]. The distinctive chemical nature of the chemical compound is manifested not in the relative activity (in the oxide, sulfide, selenide series), but in the magnitude of the activity, i.e. the degree of conversion.

As already stated, the degree of conversion is greater for nickel compounds than for chromium compounds.

The inference that we have just made concerning the part played by the structural factor is confirmed also by results obtained for the hydrogenation of one double bond of butadiene: NiS is more active than NiSe, and CrSe is more active than CrS. This is not surprising, for the difference between the interatomic distances C=C (1.33 A) and N=O (1.21 A) [9] is not great. The structural factor, i.e. the ratio of the interatomic distances in the reacting molecule and in the catalyst surface, must be approximately the same in both reactions. The effect of the structural factor can be judged also from Table 4 showing the results obtained on sulfide catalysts for the three reactions investigated [the figures for isopropyl alcohol—amount of hydrogen and propene (ml) per 1 ml of alcohol and 10 ml of catalyst; for the other two reactions—degree of conversion (%)]:

TABLE 4

c	5.30	5.67	6.28	—

Fig. 3. Dependence of catalyst activity on the covalent radius of the nonmetal: a) nickel catalysts; b) chromium catalysts; o) at 220°; Δ) at 260°; □) at 300°.

In these data we can clearly see the parallelism between activity and lattice characteristics: the most favorable interatomic distance for the accomodation of the reacting molecule on the surface is found in the NiS lattice, and the least favorable in the ZnS lattice. As the parameters of the lattice increase, the activity of the catalysts diminishes. This, of course, can be attributed to the geometry of the surface, which can be regarded as a function of the chemical nature of the catalyst.

In connection with these considerations, it is desirable to examine the effect of the structural factor on selectivity in the decomposition of an alcohol [1]. Since oxygen, sulfur, and selenium belong to the same group of the periodic system and the investigated compounds of these elements are isomorphous with the exception of cubic NiO, the difference between the orientation of the alcohol molecule on the surface by means of the CHOH group for dehydrogenation and by means of the CH_3CHOH group for dehydration must be determined mainly by the interatomic distances on the catalyst surface, for the possibility of one or the other disposition of the reacting molecule must depend on these distances. Energetic differences, on the other hand, must result in different rates of conversion in the given direction. In our case the M-X distance increases from the oxide to the selenide. As shown in the previous paper [1], the selectivity coefficients are Cr_2O_3 0.63, CrS 0.39, and CrSe 0.03, i.e. dehydration becomes more marked with increase in the interatomic distances on the catalyst surface. This occurred both on zinc and on nickel catalysts, though in the last case evolution of hydrogen sulfide and the transformation of NiS into Ni_3S_2 had considerable influence on the process. Our results are in close accord with those obtained previously for MgO [10], TiO_2 [11], Nb_2O_5 and Ta_2O_5 [12] on the effect of interatomic distance on selectivity and with theoretical considerations relating to these results [10, 11].

As the effect of the geometric factor is in evidence in the cases we have investigated, we may conclude that the reactions proceed by a doublet mechanism, not only on oxides, but also on sulfides and selenides. From the fact that activity is directly related to the interatomic distance between metal and nonmetal on the surface, we may conclude that nonmetal atoms form part of the active center and participate in the formation of the multiplet complex.

SUMMARY

1. Data was obtained on the relative activities of oxides, sulfides, and selenides of nickel, zinc, and chromium and of the corresponding mixed Ni-Zn catalysts in the reduction of nitrobenzene to aniline and the selective hydrogenation of one double bond of a diolefin.

2. It was found that in both reactions the activity falls in the sequence Ni > Cr > Zn, i.e. from compounds of the Group VIII metal to compounds of the Group II metal. Zinc catalysts were of low activity under the experimental conditions, nickel catalysts fell into the series NiS > NiSe > NiO with respect to specific activity, and for the chromium catalysts the sulfide was less active than the selenide.

3. The relationship between the activities of the catalysts, on the one hand, and their phase compositions and structures, on the other, was examined, and it was shown that the observed changes in activity and selectivity in the series oxide, sulfide, selenide are satisfactorily explained on the principle of structural correspondence of the multiplet theory of catalysis, which has again been confirmed by the results now obtained.

4. It was suggested that nonmetal atoms take part in the formation of doublets and of the multiplet complex on catalyst surfaces.

CHEMICAL CHANGES PRODUCED IN THE CELLULOSE MACROMOLECULE BY OXIDIZING AGENTS

COMMUNICATION 11. CAUSES OF THE CHEMICAL INSTABILITY OF CELLULOSES OXIDIZED WITH NITROGEN DIOXIDE

E. D. Kaverznova and S. A. Kist

It is well known that cellulosic materials, when subjected to the action of moisture, light, and various chemical agencies, undergo oxidative changes that result in a deterioration of mechanical properties and chemical stability. The oxidation of cellulose by nitrogen dioxide is associated with a particularly great change in its properties, and this behavior has not yet found an explanation in the chemical changes brough about by the oxidation. It is characteristic of such oxidized preparations that their mechanical properties deteriorate fairly rapidly with keeping and they break down readily in an aqueous alkaline medium, in spite of their fibrous structure, which cannot be distinguished visibly from that of untreated cellulose. Both these phenomena indicate breakdown of the macromolecular chain under the influence of the new functional groups formed during the oxidation. In the present investigation an attempt was made to relate the instability of these oxycelluloses to peculiarities of their chemical structure.

EXPERIMENTAL

Our previous investigations [1] showed that in the oxidation of cellulose by nitrogen dioxide not only carboxyl groups are formed, but also keto groups. Nitric esters are formed as intermediate compounds, and these then undergo oxidative hydrolysis. Some of the keto groups are oxidized further with rupture of a C—C link in the pyran ring and formation of nonuronic carboxyls. Practically no aldehyde or carbonic ester groupings are formed, and no peroxy compounds could be detected. The reactions occurring can be represented as follows:

The contents of the individual functional groups change very greatly as oxidation proceeds. Table 1 gives analyses of several freshly prepared oxycelluloses differing in degree of oxidation.

A characteristic of oxidation by nitrogen dioxide is the high content of new functional groups in the oxidized cellulose. This result is favored by the fact that reaction occurs in an atmosphere of the gas and hydrolytic processes are absent. In nitrogen dioxide oxidation the yield of oxycellulose is close to theoretical value (105-115%

on the original weight), whereas in oxidations with hypochlorite and other oxidizing agents in an aqueous medium the yield of oxycellulose falls as the duration of the oxidation increases. In Table 2 we make a comparison of the contents of functional groups in oxycelluloses prepared by the action of various oxidizing agents.

TABLE 1

Contents of Functional Groups in Oxycelluloses Prepared by Oxidation with Nitrogen Dioxide

Preparation No.	Content (%) of COOH groups	carbonyl groups	aldehyde groups	keto groups	N
33	7.5	1.02	0.02	1.00	0.37
34	9.9	3.04	0.01	3.03	0.43
Series 1	17.2	3.28	0.04	3.24	0.20
Series 2	16.8	2.62	0.07	2.55	0.18

It follows from Table 2 that, in spite of the powerful oxidation brought about by sodium hypochlorite and hydrogen peroxide, the numbers of carboxy and keto groups in the resulting oxycelluloses are very much less than in nitrogen dioxide oxycelluloses. The ratio of keto groups to carboxyls after the oxidation of cellulose with nitrogen dioxide is not high—even less than in hypochlorite and peroxide oxycelluloses—but the absolute number of keto groups is many times greater than in any other oxycellulose.

Thus, high contents of carboxy and keto groups are characteristic of celluloses oxidized with nitrogen dioxide. At the same

TABLE 2

Contents of Functional Groups in Oxycelluloses Prepared by the Action of Various Oxidizing Agents

Oxidizing agent and conditions of oxidation	Amount (equiv. per 100 glucose residues) COOH	keto groups	aldehyde groups	Keto (%) / COOH	Aldo (%) / COOH
NO_2					
5 hr 1 mol NO_2 per glucose residue, 22°	7	0.64	0.23	9	3
96 hr, 4 mol NO_2, 22°	44	15.5	0.23	35.2	0.55
120 hr, 6 mol NO_2, 20°	66	19.9	0.24	30.2	0.4

time, it is characteristic of these oxycelluloses that aldehyde groups are almost completely absent, whereas it is the presence of aldehyde groups that is generally associated with loss of stability of the cellulose macromolecule [2]. There is therefore no foundation for the view of Nabar and Padmanbhan [3], according to which NO_2-oxidized cellulose readily undergoes breakdown owing to the supposed presence of dialdehyde groupings. It was natural to turn our attention on the high content of keto groups and to elucidate their effect on the chemical properties of the oxycelluloses obtained by nitrogen dioxide oxidation.

We were interested in the effect of keto groups on the hydrolytic splitting of oxycelluloses in alkaline and acid media and on the breakdown that occurs when oxycelluloses are kept. In the oxycelluloses studied the

following functional groups are present, and they might be found in the glucose residues in the combinations indicated in the schemes:

In 1942 Kenyon suggested that the instability of oxycelluloses prepared by oxidation with nitrogen dioxide in an alkaline medium is the result of a great accumulation of electronegative COOH groups in them [4]. This point of view was supported by Rogovin, Kondrashuk, and Malakhov [5]. However, recent observations by Vollmert [6] on free pectic acids containing COOH groups in each galactose residue showed that these acids are quite stable to the action of 1% caustic soda at room temperature. The same conclusion was reached for alginic acid by Nevell [7]. There are no grounds, therefore, for the view that the presence of carboxy groups in the 6-positions of the glucose residues is in itself of significance in determining instability to alkali.

Moreover, the effect of COOH groups at C-2 and C-3 (Form III) on alkaline breakdown cannot be great, for it is known from investigations of Reeves and others [8] and of Yashunskaya, Shorygina, and Rogovin [9], that by the oxidation of the aldehyde groups of "dialdehydocellulose", its stability toward alkalis increases. In the hydrolysis of "dicarboxycelluloses" (0.3-0.6% COOH) in 0.1 N NaOH (24 hours at 90°), the COOH content falls by only 8-9%, whereas in water it falls by 41-64%, i.e. breakdown is only slight in an alkaline medium. Consequently, COOH groups in the 6-, 2-, and 3-positions have no appreciable effect on the stability of the glucoside linkage in an alkaline medium.

Since NO_2-oxidized oxycelluloses contain no aldehyde groups, but many keto groups, they may be considered to be model substances for the elucidation of the effect of keto groups on the properties of cellulose. The rapid breakdown of these oxycelluloses in an alkaline medium is well known. In illustration we show the curves for the fall in viscosity (see Figure) of alkaline solutions of oxycelluloses having the following contents of functional groups:

	COOH (%)	Keto groups (%)	N (%)
Preparation No. 2	12.9	2.32	2.82
Preparation No. 6	12.1	2.94	0.24

During the first ten minutes there is a sharp fall in viscosity, and after several hours it is no longer possible to precipitate any macromolecular material from the solution. There is every reason to ascribe such a low stability toward an alkaline medium to the keto groups present in the oxycellulose.

The effect of these groups on the stability of the acetal linkage in an alkaline medium has been studied for many compounds of low molecular weight and, in particular, for glucosides [10]. It has been shown that when there is a double bond in conjugation with the keto group [11] or the keto group is in the α- or β-position with respect to the acetal link [12] the stability of this link toward alkali is greatly reduced. The same behavior must be preserved in macromolecular compounds, and an oxycellulose containing a keto group in the α- or β-position to the glucosidic link should have enhanced sensitivity to alkalis.

Fall in viscosity for solutions of celluloses oxidized with nitrogen dioxide (solvent 0.2 %NaOH; temperature 20°; the first point represents a measurement made 4-5 minutes after the start of dissolution):
1) Preparation No. 6 at a concentration of 0.5%;
2) Preparation No. 6 at 0.4%; Preparation No. 2 at 0.4%.

Several mechanisms have been proposed for the activation of the glucosidic link by the keto group. The electronic interpretation of this phenomenon amounts to the assumption of the formation of a cationoid center on the carbonyl oxygen. The induced shift of a free electron pair from the glucosidic oxygen facilitates the approach of the OH-ion. Hibbert [13] attributes the effect to the acidity of the carbonyl group, it being well known that the higher the acidity, the lower the stability of the glucosidic link.

For oxycelluloses Schemes 1 and 2 are equally probable, since the keto group is simultaneously in an α- and a β-position to a glucosidic link.

It is quite probable that the simultaneous presence of a keto and a carboxyl group in one monomer unit will still further reduce the stability of the glucosidic link. The probability of this simultaneous presence is fairly high, even if we assume uniform oxidation along the whole chain, which is known to be untrue since oxidation by oxides of nitrogen proceeds in a nonuniform fashion. For example, for preparations oxidized to a medium extent and containing 60 carboxy and 18 keto groups per 100 glucose residues, the probability of the simultaneous presence of these groups in one unit is 0.6 x 0.18 = 0.108, i.e. 10 glucose residues out of 100 may contain COOH and CO groups simultaneously.

The direct effect of nitric ester groupings on alkaline breakdown need not be considered here, since the number of these groupings is small in normally oxidized preparations, being 1-4 per 100 glucose residues (0.1-0.3% N). When these groups are hydrolyzed in an alkaline medium, some keto groups should be formed in addition to those already present, but they will not produce substantial changes in the properties of the preparation.

Hence, from an examination of the effect of functional groups on the stability of the glucosidic link in an alkaline medium we may infer that the most notable effect is to be attributed to keto groups and may possibly be reinforced by carboxyls present. Whereas we have a well grounded explanation of the alkaline instability of oxycelluloses prepared by the action of nitrogen dioxide based on the effects of numerous keto groups, the reduction in the stability of these oxycelluloses in an acid medium is much less readily understood. Let us consider the facts. Our experiments on the hydrolysis of oxycelluloses in an aqueous medium (pH 3-4) and in presence of sulfuric acid (3.7 N) have shown that the rate at which these preparations undergo hydrolytic breakdown varies with the extent of oxidation. Slightly oxidized preparations pass into solution just as slowly as unoxidized cotton; with increase in degree of oxidation, dissolution and hydrolysis rates increase in proportion to the extent of oxidation and are several times as high as the rate of dissolution of unoxidized cellulose, as can be seen from Tables 3 and 4.

In the hydrolysis, the highly oxidized part of the chain passes preferentially into solution, so that the remaining, undissolved part of the oxycellulose is less oxidized than the original. In th solution these products of low molecular weight undergo further hydrolysis to monomers. In acid hydrolysis there is also a lowering of nitrogen content owing to hydrolysis of nitric ester groups. It should be noted that the losses in COOH groups and nitrogen were approximately equivalent for the two preparations studied, irrespective of the different original contents of nitrogen in the preparations. All the analyses for funtional groups were carried out by the method described previously [1].

TABLE 3

Hydrolysis of Oxycelluloses in Water and Acids

Preparation No.	Conditions of hydrolysis of oxycellulose	Amount of substance passing into solution	COOH content (%) of original preparation	COOH content (%) of residue	COOH content (%) of solution	Aldehyde content of substance in solution (%)
27	Water, 1 hr, 100°	1	2.53	2.32	17.6	–
20	Water, 1 hr, 100°	17	8.92	6.70	14.7	5.9
20	Water, 3 hours 100°	26	–	–	–	7.7
20	3.7 N H_2SO_4, 1 hr, 100°	32	–	–	–	15.25
Unoxidized cotton	2.5 N HCl, 1 hr, 105°	12	–	–	–	–

The lower the extent of oxidation of the preparation, the more selective is the elimination of oxidized glucose residues from it. For example, in Preparation No. 27 (2.53% COOH) the water-soluble fraction contained 17.6% COOH, and in Preparation No. 20 the fraction passing into solution contained 14.7% of carboxyls, i.e. it contained more unoxidized glucose residues.

All this indicates that the hydrolytic breakdown of oxycelluloses proceeds primarily at the oxidized units of the cellulose chain and that the rate of breakdown is greater for oxycelluloses than for the unoxidized cellulose.

TABLE 4

Passage of Nitrogen and Carboxy Groups into Solution in the Acid Hydrolysis of Oxycelluloses •

(5 g of oxycelluloses was heated in water for 1 hour at 100°)

Preparation No.	Content (equiv. per 100 glucose residues) of		Amount of substance passing into solution (%)	COOH content (mmoles)					Nitrogen content (mmoles)			
	COOH groups	N atoms		in original a	in residue b	in solution a−b	by direct titration	COOH passing into solution (% on original)	in original	in residue	in solution	Nitrogen passing into solution (% on original)
27	91	14.5	1	2.81	2.62	0.19	0.195	6.9	4.27	3.57	0.26	6.1
20	33	5.	17	9.91	6.18	2.73	2.78	28.0	1.57	0.65	0.50	31.7

• In the hydrolysis carboxylic acids and HNO_3 or HNO_2 pass into solution. It is therefore not altogether clear why the results of direct titration of acidity after hydrolysis (i.e. COOH + NO_3^-) should coincide with the amount of COOH in solution as determined from the difference in the COOH contents of the original preparation and the residue after hydrolysis. It is possible that decarboxylation occurs, and this compensates for the rise in acidity due to nitrous acid.

What chemical changes occurring during oxidation and what functional groups are responsible for the reduced stability of oxycelluloses in an acid medium? There are few data in the literature on this matter. For pectic and alginic acids in an acid medium (20% HCl at 60°) the hydrolysis rate constants have been found to have the same order of magnitude as the constant for cellulose [14].

	$K \cdot 10^3$ (hour^{-1})
Pectic acid, pH 0.3, 70°	13.1 [15]
Pectic acid, 20% HCl, 60°	14.0 [16]
Cellulose, 20% HCl, 60°	12.0 [16]

It appears that a COOH group in the 6-position does not affect the properties of the glucosidic link in an acid medium. For "noncarboxycelluloses" oxidized to the extent of 20% COOH, Konkin, Smirnova, and Rogovin [16] also did not find any increase in the hydrolysis rate constant. However, these experiments are not altogether convincing owing to possible errors of method. In these experiments the rate of hydrolysis was followed by determining the increase in the number of aldehyde groups in solution by the iodometric method. In this case the number of aldehyde groups found might not correspond to the course of the breakdown of the oxycellulose macromolecule for the following reasons: 1) breakdown might occur without formation of aldehyde groups, for it might occur at oxygen bridges in opened pyran rings; 2) the hydroxy and keto aldehydes formed in the hydrolysis of strongly oxidized preparations rapidly undergo further reactions with loss of aldehyde groups when heated in an acid medium. Hence, the hydrolysis rate constant based on aldehyde contents does not characterize the actual processes occurring.

We must consider separately the possibility of breakdown in an acid medium at the opened pyran rings referred to above:

Jackson and Hudson [17] examined the behavior of diglycolic acid, obtained by the oxidation of cellulose with hypobromite, and they demonstrated the low stability of the oxygen bridge in this compound: it was broken down by boiling for two hours with water (which would form a slightly acid medium). Hence, when such oxygen bridges occur in oxycelluloses, breakdown of the macromolecular chain may occur as a result of the hydrolytic rupture of these bridges. The experiments of Rogovin, Kondrashuk, and Malakhov [5] offer some possibility of estimating the extent of this breakdown. They compared the stabilities to hot water, i.e. an acid medium, of two samples of oxycelluloses in which COOH groups were present in equal amount (2.8%) but in different positions: in the 6-positions of the glucose residues of cellulose oxidized with nitrogen dioxide, and in the 2- and 3-positions in a preparation obtained by successive oxidation with sodium periodate and with chlorine dioxide. Heating with water at 100° for three hours had almost no effect on the strength and extensibility of the second preparation, but broke down the NO_2-oxidized preparation to a powder. Hence, if oxygen bridges in opened glucose residues cause chain breakdown, then in oxycelluloses prepared by oxidation with nitrogen dioxide there are some other, very much more potent factors contributing to breakdown. The authors consider this factor to be the presence of the carboxyl in the 6-position, a view that is in conflict with the results of Konkin and others.

The oxycellulose preparations studied by Rogovin and coworkers [18] differed not only in the positions of the carboxyl groups in the glucose residues, which, as we have seen, are not of determining significance for the rate of hydrolysis; they differed also with respect to the presence of keto groups, which are present in NO_2-oxidized cellulose, but absent in "dicarboxycellulose" [1]. It is therefore necessary to examine how this group can affect the stability of the glucosidic link in an acid medium. The work of Fisher, Hawkins, and Hibbert [13] may be cited here: this showed that a carbonyl group in the para position to a phenolic hydroxyl in the aglycon has little effect on the hydrolysis of the glycosidic link.

(a) (b)

In 0.1% sulfuric acid at 100°, the half-life of (a) is 15 minutes and that of (b) is 20 minutes. The hydrolysis rate constant of turanose (3-α-glucosylfructose) in an acid medium is of the same order as the constant for maltose (4-α-glucosylglucose) $K_{aH} \cdot 10^5$ (sec^{-1}) is 11.9 for turanose and 16.8 for maltose [19].

Hence, no direct effects of carboxyl and keto groups on the stability of oxycelluloses in an acid medium have been established. The question of their effect when present simultaneously in a single glucose residue of the macromolecule remains open.

Nevertheless, it remains a fact that breakdown during heating with water is much more intense for preparations that have been particularly severely oxidized. It is most probable that the cause of the comparatively ready passage into solution of oxycelluloses obtained by the action of nitrogen dioxide, when these are heated in an acid medium, is not isolated activation of glucosidic links in the presence of some particular functional group, but the simultaneous operation of several factors.

It is now almost universally considered that the main cause of the difficulty with which cellulose is hydrolyzed lies in its physical state — the packing of the macromolecular chains, these being bound together by a large number of hydrogen bonds, which hinder hydrolysis. In the course of oxidation, particularly the severe oxidation produced by nitrogen dioxide, hydrogen bonds must be broken and rearranged, and the uniformity of packing must be disturbed. As a result, weak places must appear in the macromolecule. This will facilitate the swelling of the oxycelluloses in water and hydrolytic breakdown in the places modified by oxidation. The extent to which the disturbances in the structure may proceed can be judged from the fact that, when the oxidized preparation contains 17% COOH, of the 300 OH groups present in 100 glucose residues, about 80 have been transformed into other functional groups.

The greater the extent of the oxidation, the greater will be the disturbance in the packing of the macromolecules and the more numerous will be the monomer units that contain both COOH and CO groups, i.e. chemically weakened places. The existence in our oxycelluloses of severely oxidized units containing both carboxy and keto groups appears still more likely in the light of recent work by Battenberg and Berg [20], who hydrolyzed NO_2-oxidized cellulose (13% COOH) with water in a CO_2 atmosphere under pressure and obtained a 3% yield of 3,5-dihydroxy-4H-pyran-4-one. This compound could be formed from a severly oxidized glucose residue of the oxycellulose in the following way:

Hence, in order to explain the breakdown of oxycelluloses in an acid medium it is necessary to take at least three factors into account: the disturbance of the order in the supermolecular structure of the macromolecules in the cellulose fiber arising from its oxidation; the chemical effect of COOH and CO groups in one monomer unit on the glucosidic link; and the formation of unstable units made up of opened rings.

Our efforts to find the causes of the breakdown of oxycelluloses during storage led to more definite results. The results of some experiments that we have carried out can be regarded as a proof of the effect of keto

groups on the chemical stability of oxycelluloses during storage. These experiments were briefly as follows: samples of oxycelluloses were kept under various conditions (in the dry state over calcium chloride, in the air-dry state in closed bottles, and in the varying humidity of the atmosphere) for periods of from 6 months to 2 years 6 months, and then subjected to external examination and chemical analysis. The results are given in Tables 5 and 6.

TABLE 5

Outward Changes in Oxycelluloses during Storage

Preparation No.	Chemical composition	Duration of storage (years)	Conditions of Storage		
			in a desiccator	in the air-dry state	in the atmosphere
1	8.2% COOH 4% N	2.5	White, fibrous, does not rub into a powder	Brown, fibrous, rubs into a powder	Brown, partially falls to a powder
7	12.5% COOH	2.5	Cream, fibrous, not readily pulverized	Yellow, fibrous, readily pulverized	Reddish, very friable, partially falls to a powder
14	16.2% COOH 0.1% N	1.5	White; fibers strong		Reddish, fiber falls to a powder

TABLE 6

Chemical Changes in Oxycelluloses during Storage in the Air-dry State

4	15	17.4	—	0.44	0.33	—	—

* Kept for 34 months.

Two main conclusions follow from Table 6: 1) in presence of moisture, breakdown of oxycellulose macromolecules occurs, this being manifested in change of color and mechanical strength and the appearance of new aldehyde and carboxyl groups; the nitrogen content falls to 0.1÷0.2%; 2) in absence of moisture the breakdown of oxycelluloses is almost completely prevented.

In the storage of oxycelluloses it is possible that hydrolytic breakdown can occur under the influence of the acidity created by the COOH groups themselves. This possibility is discussed in a paper by Davidson and Standing [21], who found that, after celluloses oxidized with hypobromite in an alkaline medium and containing 0.4-1.5% COOH had been kept for 12 months, divergencies began to appear in the results of the determination of carboxy groups by the calcium acetate method and the methylene blue method. The authors considered that autohydrolysis occurred and some of the carboxy groups present in the breakdown products of low molecular weight went into solution during the methylene blue determination and could therefore not be determined. It is true that the amount was very small (0.009-0.09% COOH). Our qualitative observations show that the breakdown of NO_2-oxidized celluloses is determined by other causes, for partially neutralized preparations of lower acidity were less stable to storage than preparations containing free carboxy groups. Observations on pectic substances and other polyuronic acids, which are stable to keeping, also did not confirm the suggestion that there is an

appreciable effect attributable to autohydrolysis of oxycelluloses due to their own acidity. We were unable to establish any relationship between the contents of nitric ester groupings in oxycelluloses and the rates of breakdown during keeping.

In order to determine the effect of keto groups on breakdown during keeping, the following experiment was carried out. The oxycellulose was treated with hydroxylamine in a weakly acid medium in order to block carbonyl groups, washed until reaction for hydroxylamine in the washings was negative, dried, and allowed to lie in the air-dry state. The experimental results (Table 7) show that, in spite of the presence of moisture, oxycellulose with blocked carbonyl groups preserves its color and mechanical properties for 2 years 6 months. The main chemical index of breakdown the content of aldehyde groups— changed insignificantly as compared with its increase in the preparation kept in the untreated condition. This experiment shows that carbonyl groups —in our case keto groups—form the main factor determining breakdown in the air in a weakly acid medium. Blocking of the carbonyl groups makes preparations stable to keeping irrespective of the presence of moisture.

TABLE 7

Comparison of Changes during Storage in Oxycelluloses having Free and Blocked Keto Groups

Preparation No.	Original analysis	Duration of Storage	Condition after storage in air-dry state	
			with free keto groups	after conversion into oxime
2	12.9% COOH 2.82% N, 0.5% aldehyde groups	2.5 years	Brown, rubs into a powder; 1.4% aldehyde groups	Cream, fibrous, fiber has some strength; 0.18% aldehyde groups
1	2.5% COOH	5.5 years	Brown, friable	Cream, fibrous; 0.43% aldehyde groups

No neutralization of carboxy broups occurred in the treatment with hydroxylamine, since the reaction was carried out in an acid medium. The carboxy groups in the hydroxylamine-treated preparations remained free, but the oxycelluloses were not degraded. It follows that autohydrolysis of the oxycelluloses as a result of their own acidity is only of secondary importance. Breakdown occurs as a result of change in the chemical stability of the glucosidic link brought about by the presence of a keto group. Whether this breakdown is hydrolytic or is associated with oxidative processes involving atmospheric oxygen has not yet been studied. It is most probable that oxidative-hydrolytic breakdown occurs, since the number of carboxyl groups, and apparently also keto groups, increases during keeping.

Hence, it follows from an examination of the changes undergone by NO_2-oxidized cellulose in an alkaline medium, during acid hydrolysis, and during keeping in presence of atmospheric moisture that its chemical stability is very much less than that of unoxidized cellulose. The main cause of this instability to alkali and to keeping in the air is the high content of keto groups in the oxidized preparations. The high tendency for these oxycelluloses to undergo hydrolysis in an acid medium makes its appearance only when oxidation has proceeded to an appreciable extent (at above 2-3% COOH), and it probably depends on the simultaneous effects of several factors, among which the most important may be: the destruction of molecular interaction, the appearance of weak links in the chain owing to the formation of opened pyran rings, and the change in the stability of a glucosidic link between glucose residues that may contain several new functional groups simultaneously.

SUMMARY

1. Oxycelluloses prepared by nitrogen dioxide oxidation are highly unstable in an alkaline medium and readily break down when kept in presence of moisture and air. The higher the degree of oxidation of these oxycelluloses, the more readily do they undergo acid hydrolysis.

2. In absence of moisture, breakdown during storage is greatly retarded.

3. When the keto groups of the oxycelluloses are blocked, degradation during storage stops almost completely whether moisture is present or not.

4. The main cause of the degradation in an alkaline medium is the large number of keto groups present in the oxycelluloses – there may be as many as 15-18 per hundred glucose residues. It is probable that the simultaneous presence of keto and carboxy groups in one monomer unit results in still higher instability in such glucose residues.

5. The main cause of breakdown during storage in the atmosphere in presence of moisture lies in the influence of keto groups, as is shown by the effect of blocking these groups.

6. The hydrolytic breakdown of the oxycelluloses studied under the action of an acid medium is not appreciably accelerated by the presence of only carboxy, or of only keto groups. It is probable that breakdown in an acid medium depends on the simultaneous effects of several factors, which come into being as a result of the oxidation. The most important of these factors may be: destruction of the ordered system of molecular interactions owing to the effect of new functional groups, and, to a less extent, changes, resulting from the presence of these groups, in the chemical stability of the macromolecular chain; some importance must be attached also to modified monomer units consisting of opened pyran rings and severely oxidized glucose residues in which both COOH and CO groups are present simultaneously.

APPLICATION OF THE IODOFORM REACTION TO THE ANALYSIS OF SOME VINYL COMPOUNDS

M. F. Shostakovsky, F. P. Sidelkovskaya, and M. G. Zelenskaya

It is well known that compounds containing the group CH_3CO- or CH_3CHOH- readily form iodoform when treated with alkali and iodine [1]. Esafov and Stafeeva [2] showed that α,β-unsaturated ketones also give the iodoform reaction, although neither of these groups is present. Such groups, however, are formed by the hydrolytic splitting of the α,β-unsaturated ketones in presence of alkali:

$$RCH{=}CHCOC_2H_5 + H_2O \rightarrow \underset{\underset{OH}{|}}{RCH}{-}CH_2COC_2H_5 \rightarrow R\overset{\overset{O}{\|}}{C}H + CH_3COC_2H_5 \qquad (1)$$

The hydrolysis products indicated in the equation react with alkali and iodine with formation of iodoform [2].

In the present investigation it was found that the iodoform reaction can be extended to not only unsaturated ketones, but also such substances as vinyl ethers (I) and N-vinyl lactams (II):

$$CH_2{=}CHOR \quad (I), \qquad CH_2{=}CH{-}N\overset{(CH_2)_n}{\diagdown\!\!\diagup}CO \quad (II)$$

in which n = 3, 4, 5.

In this case the formation of iodoform is not associated with the hydrolysis of an unsaturated compound (which could yield acetaldehyde). It is well known, for example, that vinyl ethers are not hydrolyzed in alkaline solutions [3]. As regards vinyl lactams, a special investigation showed the absence of hydrolytic breakdown during treatment with alkali under the conditions of the iodoform reaction (i.e. at room temperature); even when the treatment was for nine hours at 60°, no hydrolysis products could be isolated (Table 2).

We consider that the formation of iodoform from vinyl ethers and N-vinyl lactams (and also, possibly from α,β-unsaturated ketones) is due to direct reaction of the double bond with iodine and alkali. This view is in full accord with the established view on the mechanism of the iodoform reactions of acetone and acetaldehyde. It is considered that in these reactions acetone and acetaldehyde react not in the keto, but in the enol form, the double bond of which combines either with two atoms of iodine formed by the decomposition of hypoiodite, or with hypoiodite itself (compare the addition of hypochlorite to ethylene). A series of successive transformations (through mono-, di-, and tri-iodoacetaldehyde) results in the formation of iodoform. It was proved that substances that are incapable of reaction in the enol form, i.e. do not contain reactive double bonds (e.g. paraldehyde), do not give the iodoform reaction [4].

It is evident that in the case also of vinyl ethers (and N-vinyl lactams), in the reaction with alkali and iodine the primary act is the addition of two atoms of iodine with subsequent breakdown of the α,β-diiodo derivatives (Equation 2), or of KOI with further reaction according to Equation 3:

$$CH_2{=}CHX + I_2 \rightarrow CH_2I{-}CHIX \xrightarrow{H_2O} CH_2ICHO + XH + HI. \qquad (2)$$

TABLE 1

Behavior of some Vinyl Compounds in the Iodoform Reaction

No.	Class of compounds	Formulas of compounds	Positive or negative reaction
1	Alkyl vinyl ethers	$CH_2=CHOR$ (R = $-CH_3$, $-C_2H_5$, $-C_3H_7$-i, $-C_4H_9$, $-C_5H_{11}$-i, $-C(CH_3)_3$, $-C_5H_{11}$-i $-CH(CH_3)CH_2CH_2CH_3$, $-C(CH_3)_2CH_2CH_3$ $-C_6H_{11}$-cyclo	Positive
2	Aryl vinyl ethers	$CH_2=CHOAr$ (Ar = $-C_6H_5$, $-C_6H_4OCH_3$)	Negative
3	Vinyl ethers of glycerol, glycols, and their derivatives	$CH_2=CHO(CH_2)_2OR$ (R = $-CH_3$, $-C_2H_5$, $-CH_2CH_2OH$), $O[(CH_2)_2OCH=CH_2]_2$; $CH_2=CHOCH(CH_2OCH=CH_2)_2$	Positive
4	Vinyl ethers of ethanolamines	$NH_2(CH_2)_2OCH=CH_2$, $N(CH_2)_2OCH=CH_2)_3$, $N(CH_2CH_2OH)_3$, $N(CH_2CH_2OCH=CH_2)_3$, $N(CH_2CH_2OH)_2CH_2CH_2OH$	
		$N(CH_2CH_2OCH=CH_2)_3$	Negative
		$C_6H_5NHCH_2CH_2OCH=CH_2$	"
		$(C_6H_5)_2NCH_2CH_2OCH=CH_2$	"
5	N-Vinyl lactams	$N(CH_2)_n-CO$ / $CH=CH_2$ ($n = 3,4,5$)	Positive
6	Vinyl esters	$CH_2=CH-OCOCH_3$	"
7	Vinyl sulfides	$CH_2=CH-S-C_2H_5$	Negative

$$CH_2=CHX+KOI \rightarrow CH_2ICH(X)(OK) \rightarrow CH_2ICHO+KX \quad (3)$$

in which X = —OR or $-NCO(CH_2)$

In both cases the reaction product is iodoacetaldehyde, which then reacts with iodine and alkali in the usual way. The overall process can be represented by the equation:

$$CH_2=CHX+3I_2+KOH+H_2O \rightarrow CHI_3+3HI+XH+COOK. \quad (4)$$

In Table 1 will be found a list of the vinyl compounds whose behavior in the iodoform reaction was studied. A negative reaction was found for those containing an aromatic nucleus. It is known from the literature [5] that in a number of cases the presence of an aromatic nucleus interferes with the iodoform reaction. The authors explained this phenomenon as the effect of steric factors [5]. It is very probable that

the inertness of vinyl ethers containing a benzene ring is to be explained not only by steric hindrance, but also by the character of the double bond in these compounds.

The iodoform reaction is not given also by vinyl sulfides $CH_2=CHSR$ owing to combination of iodine with the sulfur atom.

Apart from vinyl compounds we have tested some acetals and allied compounds in the iodoform reaction. The substances examined were the symmetrical acetals $CH_3CH(OR)_2$, in which R=CH_3, C_2H_5, C_3H_7-i, C_4H_9, C_8H_8, and the mixed acetals $CH_3CH(OCH_3)OC_4H_9$, $CH_3CH(OC_4H_9)OC_8H_{15}$, $CH_3CH(OC_2H_5)OCH_2CH_2OH$, $CH_3CH(OC_4H_9)OC_8H_4OCH_3$, $CH_3CH(OC_2H_5)OC_8H_{11}$, $CH_3CH(R')NCO$, R' = C_2H_5, C_8H_9.

When a carefully purified acetal was used in the reaction, the result, without exception, was negative: after addition of alkali and iodine the solutions remained quite clear, and no precipitate of iodoform was formed. Hence, the iodoform reaction can be used as a supplementary test in the qualitative analysis of vinyl ethers and N-vinyl lactams, enabling them to be distinguished from, for example, the corresponding acetals.

It was of interest also to determine the possibility of using this reaction for the quantitative determination of the vinyl compounds studied. For N-vinyl lactams only one method is known for their quantitative determination, this being based on their hydrolytic breakdown in an acid medium [6]; on the other hand, numerous papers [7] have been devoted to the quantitative analysis of vinyl ethers. In the present investigation, therefore, attention was directed mainly to the possibility of the use of the iodoform reaction in the analysis of N-vinyl lactams, particularly as these are readily soluble in water and the performance of the analysis does not present any experimental difficulties.

It is well known that the iodoform method is used for the quantitative determination of acetone, one molecule of which requires six atoms of iodine. There is no exact information in the literature of the quantitative determination of acetaldehyde and iodoacetaldehyde by this method—only some isolated conflicting statements [8]. It has been established [9] that the best results are obtained in the determination of acetaldehyde when the following conditions are observed: reaction temperature 25°, duration 25 minutes, mixture of reactants in following order—add weighed sample of substance to be analyzed to alkali solution, and then add the necessary amount of iodine. But even under such conditions, acetaldehyde was accounted for only to the extent of 80%. This behavior results from the simultaneous occurrence of two reactions when the aldehyde is treated with iodine and alkali:

$$CH_3CHO + 6I + 4KOH \rightarrow CHI_3 + 3KI + HCOOK + 3H_2O. \quad (5)$$

$$CH_3CHO + 2I + 3KOH \rightarrow CH_3COOK + 2KI + 2H_2O. \quad (6)$$

Reaction (5) results in the formation of iodoform (6 atoms of iodine are consumed per molecule of acetaldehyde), and reaction (6) consists in the oxidation of aldehyde to acid (2 atoms of iodine are consumed per molecule of acetaldehyde). Thus, for formaldehyde, in which the methyl group is absent and the enol form cannot exist, reaction (6) proceeds quantitatively. Hence, the actual stoichiometric coefficient for the reaction between acetaldehyde, iodine, and alkali varies between 2 and 6.

When the above-stated conditions were verified for N-vinylcaprolactam [2-oxo-1-vinylhexamethyleneimine], it was found that they are indeed optimum. However, as in the case of acetaldehyde, when the results of the analysis were calculated from Formula I (see below) on analogy with acetone and in accordance with Equation 4—the extent to which the vinyl lactam was accounted for was only about 75%.

$$\%VL = \frac{(a-b)\,FM}{p \cdot 6 \cdot 100} \cdot$$

in which a is the amount (ml) of thiosulfate solution required in the control experiment, b is the amount (ml) of thiosulfate solution required in the actual determination, F is the correction factor to 0.1 N thiosulfate, M is the molecular weight of the vinyl lactam under investigation, and p is the weight taken of the vinyl lactam.

TABLE 2

Mean				4.58	Mean				4.62	Mean				4.65

It is evident that also in the iodoform determination of vinyl lactams, reactions analogous to (5) and (6) occur (in this case, reaction is with iodoacetaldehyde).

As it was found that in the determination of vinyl lactams very concordant results were always obtained and the analytical procedure was very simple and rapid, we considered that, without undertaking the task of establishing the actual mechanism of the reaction, it would be very desirable to find an empirical formula for the calculation of the analytical results. For this purpose we applied the graphical method, so widely used in analytical chemistry.

Determination of the coefficient K: ●– 1-vinyl-2-pyrrolidinone; ○ – 1-vinyl-2-piperidone; △ – N-vinylcaprolactam.

We obtained a straight line (see Figure), which can be described by the equation $y = Kx$. The proportionality coefficient K is the ratio between the numbers of vinyl lactam molecules and iodine atoms that react together, i.e. in effect the stoichiometric coefficient for the reaction studied (for numerical data see Table 2). The vinyl lactam content of a weighed sample of material can therefore be calculated from Formula II (see Experimental).

For N-vinylcaprolactam K = 4.62, for 1-vinyl-2-piperidone 4.65, and for 1-vinyl-2-pyrrolidinone 4.56. For vinylcaprolactam and vinylpiperidone K can be determined accurate within ± 1%, and for vinylpyrrolidinone accurate within ± 1.5%. The coefficients found are practically all the same.

By the use of Formula II, very satisfactory results were obtained in the quantitative determination of vinyl lactams. Hence, when an error of up to 2-3% is permissible in analysis, the iodoform reaction can be used successfully for the determination of the substances indicated, particularly in aqueous solutions.

EXPERIMENTAL

Reaction of N-Vinylcaprolactam with Water in Presence of Caustic Potash

A mixture of 10.1 g of N-vinylcaprolactam (2-oxo-1-vinylhexamethylenimine) [b.p. 90.5-91° (1.5-2mm), n_D^{20} 1.5130] and 200 ml 1N KOH was prepared in a three-necked flask fitted with stirrer, thermometer, tube for passage of nitrogen, and reflux condenser connected to three Tishchenko vessels. It was heated for 30 hours at 99-101° in a current of nitrogen. The reaction mixture was extracted with four successive 20-ml portions of ether. The ether extracts yielded 5.93 g of vinylcaprolactam [b.p. 91-91.5° (2 mm), n_D^{20} 1.5097] and 0.6 g of resin. The water layer was neutralized with hydrochloric acid and evaporated. Extraction of the residue with alcohol gave 2.64 g of crystals, which distilled with decomposition. Fractional distillation of this product gave 0.25 g of a substance b.p. 101-107° (2.5 mm), m.p. 32-40° which was found to be a mixture of vinylcaprolactam and caprolactam. Titration of the bisulfite solution contained in the Tishchenko absorption vessels gave the acetaldehyde content (0.22 g of acetaldehyde, corresponding to 0.69 g of vinylcaprolactam, was found). The conditons under which the remaining experiments on the reaction between vinylcaprolactam and water and between 1-vinyl-2-pyrrolidinone and water in presence of alkali were carried out are given in Table 3 together with the results of these experiments.

TABLE 3

Behavior of N-Vinylcaprolactam and 1-Vinyl-2-pyrrolidinone Toward Water in Presence of 1N KOH (amount of vinyl lactam taken 9-10 g).

Name of vinyl lactam	Amount of N KOH taken (ml)	Reaction temperature (°C)	Duration of experiment (hours)	Amount of vinyl lactam recovered unchanged (g)	Amount of acetaldehyde found (%)	Resinous products obtained (g)
N-Vinylcaprolactam	100	57—50	5	8.74	—	0.5
"	200	57—50	9	6.45	—	0.98
"	200	98—101	9	4.22	5.77	0.35
"	200	98—101	26	4.78	17.61	1.23
1-Vinyl-2-pyrrolidinone	200	98—101	26	0.37	10.84	3.80

Qualitative Determination of Vinyl Compounds by the Iodoform Method

Experimental Procedure. A test tube containing 2 ml 1N KOH and one drop (0.03-0.05 ml) of the compound under investigation was shaken while 2 ml of 0.1 N iodine was added. A large excess of iodine interferes with the test, since under these conditions the iodoform dissolves. In the presence of the compounds indicated in Table 1, a turbidity appeared and later settled as a precipitate of iodoform with its characteristic odor.

Quantitative Determination of Vinyl Lactams by the Iodoform Method

a) Experimental Determination of the Proportionality Coefficient. A 1.0-g sample of the freshly distilled vinyl lactam was dissolved in 1 liter of distilled water. An exact amount of this solution (10-50 ml, generally measured by buret) and 25 ml 0.1N iodine were added to 25 ml 1 N KOH contained in a flat-bottomed conical flask. The mixture was kept at 23-25° for 25 min; then acidified with 1N HCl (26 ml). The excess of iodine was titrated with thiosulfate. Knowing the amount y of iodine consumed by the amount (g-equiv) of vinyl lactam taken for analysis x, we calculated the value of K (Table 2).

b) Determination of the Concentration of Vinyl Lactam. In the determination of the concentration of vinyl lactam we used the same procedure. The calculation was carried out by Formula II:

$$VL = \frac{(a-b)\cdot Fkl}{p \cdot K \cdot 100} \quad (1)$$

in which K is the empirically found proportionality coefficient.

SUMMARY

1. It was shown that many vinyl compounds (vinyl ethers, N-vinyl lactams) give the iodoform reaction, and this fact can be applied to the qualitative analysis of these compounds.

2. It was shown that vinyl lactams undergo practically no hydrolysis in presence of alkali.

3. A mechanism is proposed for the formation of iodoform by the action of alkali and iodine on the vinyl compounds indicated.

4. A procedure was developed for the quantitative determination of N-vinylcaprolactam, 1-vinyl-2-pyrrolidinone, and 1-vinyl-2-piperidone by the iodoform titration method.

BRIEF COMMUNICATIONS

USE OF A NICKEL CATALYST IN THE KIZHNER DECOMPOSITION OF HYDRAZONES

N. I. Shuikin, I. E. Grushko, and I. F. Belsky

As is well known, in 1911 Kizhner [1] found that aldehydes and ketones can be converted into the corresponding hydrocarbons by catalytic decomposition of their hydrazones:

At first, Kizhner used caustic potash for the decomposition of hydrazones, but later he showed that more complete reaction, with higher yields of the corresponding hydrocarbons, could be obtained by the joint action of caustic potash and platinum.

For the hydrazone-decomposition reaction, Cook and Linstead [2] used palladium instead of platinum. Thus, in the preparation of cis-octahydropentalene they used palladium supported on barium sulfate as catalyst. For similar purposes, Fischer and Krauss [3] successfully used palladium on calcium carbonate.

In the present investigation we studied the use of finely divided nickel as catalyst for the Kizhner reaction. With this object we carried out comparative experiments on the decomposition of hydrazones of 2-(1-cyclohexen-1-yl) cyclohexanone and furyl methyl ketone in presence of platinized alumina (20% Pt), reduced nickel-alumina catalyst (30% Ni), and nickel black. We showed that, in the Kizhner reaction, a platinum catalyst can be successfully replaced by a more accessible nickel catalyst.

EXPERIMENTAL

2-(1-Cyclohexen-1-yl) cyclohexanone was prepared by the self-condensation of cyclohexanone in presence of hydrogen chloride and decomposition of the 2-(1-chlorocyclohexyl) cyclohexanone formed by means of 20% caustic potash solution. It had the following properties: b.p. 110° (7 mm); n_D^{20} 1.5073; d_4^{20} 0.9990; Found MR 53.11; Calculated $C_{12}H_{18}O$ MR 52.76.

Furyl methyl ketone was prepared by Hartough and Kosak's method [4], which consists in the acetylation of furan by means of acetic anhydride in presence of hydriodic acid. It had b.p. 46-48° (5 mm) and m.p. 31°.

In the preparation of the hydrazones, 90% hydrazine hydrate, taken in 10-20% excess, was added to an ethanolic solution of the ketone; the reaction mixture was then heated in a water bath for 3-4 hours. In addition to the hydrazines, small amounts of azines were obtained in this reaction, and these were isolated when the reaction products were vacuum-distilled: they are yellow crystalline substances, insoluble in water, but readily soluble in alcohol, ether, and benzene. The azine obtained from 2-(1)cyclohexen-1-yl) cyclohexanone melted at 103°:

Found %: N_2 7.85
$C_{26}H_{26}N_2$. Calculated %: N_2 7.94

The azine from furyl methyl ketone melted at 95-96°:

Found %: N_2 13.51
$C_{11}H_{11}O_2N_2$. Calculated %: N_2 12.95

Alcohol was distilled off, and the hydrazones were carefully dried with anhydrous calcium chloride. They were then decomposed with freshly calcined caustic potash (10% on the weight of the hydrazone in presence of catalyst (0.1% of platinized alumina, 0.5% of nickel on alumina, or 2% of nickel black).

Nickel on alumina (30% Ni) was prepared from nickel and aluminum nitrates by the method developed by Shuikin and coworkers [5]. Nickel black was prepared by leaching the aluminum from a nickel-aluminum alloy (27% Ni) with dilute caustic soda solution.

The hydrazones were decomposed in a Claisen flask fitted with condenser set for distillation. It was necessary to initiate reaction by slight warming, after which it went fairly vigorously. It was found that care is necessary to prevent overheating of the reaction mixture, as the liquid may then be thrown over into the receiver. In order to complete the decomposition it is desirable to add a little fresh catalyst toward the end of the operation.

The catalyzates were treated with dilute acetic acid, washed with water, and dried over calcined calcium chloride. When distilled over sodium, 1-cyclohexylcyclohexene came over at 235° (752 mm); it had n_D^{20} 1.4942; d_4^{20} 0.9082; Found MR 52.57; Calculated $C_{12}H_{20}$ MR 52.75.

2-Ethylfuran distilled at 91-91.5° (750 mm) and had n_D^{20} 1.4402; d_4^{20} 0.9018; Found MR 28.11; Calculated C_6H_8O MR 28.42.

The results of the hydrazone-decomposition experiments are given in the table.

TABLE 2

Yields of Hydrocarbon and 2-Ethylfuran (%) in the Decomposition of Hydrazones in Presence of Various Catalysts

Original substance	$Pt-Al_2O_3$	$Ni-Al_2O_3$	Ni black
Hydrazone of 2-(1-cyclohexen-1-yl)cyclohexanone	60.8	58.0	55.0
Hydrazone of furyl methyl ketone	72.0	75.0	69.0

Our experiments have therefore established that nickel deposited on alumina (30% Ni) and nickel black can be used successfully for the decomposition of the hydrazones of 2-(1-cyclohexen-1-yl, cyclohexanone and furyl methyl ketone. Moreover, these experiments show that the hydrazones of ketones of various structures can be decomposed with adequate completeness not only in presence of platinum, but also in present of a nickel catalyst.

SUMMARY

It was shown that, in some cases, various forms of finely dispersed nickel (nickel on alumina and nickel black) can be used instead of a platinum catalyst, and with equal effect, in the hydrazone-decomposition reaction.

SULFONATION OF TERT-BUTYL-SUBSTITUTED THIOPHENES

Ya. L. Goldfarb, L. V. Antik, and P. A. Konstantinov

It is known that compounds which have aromatic functions and carry a tert-butyl group have certain peculiarities associated with the screening effect of this group. New data have recently appeared in the literature concerning this effect of the tert-butyl group [1-3]. The steric effect of the tert-butyl group is apparent not only in cases when compounds containing this group do not enter this or that reaction, but also in cases in which attempts are made to introduce a tert-butyl group into an aromatic system. Examples of this sort can be found in the work of Schlatter [4]. This investigator found that m-xylene is tert-butylated exclusively in the 5-position, and p-xylene will scarcely undergo tert-butylation. In these and other cases there is a tendency for the tert-butyl group to enter a position that is spatially far removed from other substituted groups. However, the general picture that is obtained on the basis of such facts does not yet enable us to predict the behavior of individual compounds containing a tert-butyl group. Thus, contrary to expectation, no clear distinction could be drawn between 2,5-di-tert-butyl- and 2,5-dimethyl-thiophenes in their desulfurization in presence of Raney nickel. The first of these compounds, like the second, is readily acetylated in presence of stannic chloride and readily undergoes King formylation; on the other hand, 3,5-di-tert-butyl-2-methylthiophene is not formylated and forms an acetyl derivative only as the result of the elimination of one tert-butyl group. In view of these results, it appeared to be of interest to accumulate further facts relating to the properties of tert-butyl-substituted thiophenes, investigating, in particular, their behavior toward sulfonating and nitrating agents.

In the present paper we give the results of a study of the sulfonation of 2,5-di-tert-butylthiophene (I), 3,5-di-tert-butyl-2-methylthiophene (II), and 2-tert-butyl-5-methylthiophene (III). As sulfonating agents we used a solution of sulfur trioxide in dichloroethane and pyridine-bis[sulfur trioxide], which has been extensively applied to the sulfonation of acidophobic systems by Terentyev [5].

The first compound (I), when treated with a solution of SO_3 in dichloroethane (40% excess of SO_3), formed a monosulfonic acid, which we isolated in about 75% yield in the form of the sodium salt. The sulfonation of (I) with pyridine-bis[sulfur trioxide] on dichloroethane gave the same monsulfonic acid. In order to characterize the sulfonic acid, we prepared its acid chloride and p-toluidine salt. It was shown that the acid was 2,5-di-tert-butyl-3-thiophenesulfonic acid, for when hydrolyzed in presence of phosphoric acid it gave the original 2,5-di-tert-butylthiophene, which was brominated to a dibromo derivative identical with the previously described 3,4-dibromo-2,5-di-tert-butylthiophene [6].

When the sulfonation of (I) was carried out in presence of a large excess of SO_3 in dichloroethane solution [5 moles of SO_3 per mole of (I)], one of the tert-butyl groups was eliminated with formation of a tert-butylthiophenedisulfonic acid, in which one of the sulfo groups was evidently in an α-position. The unchanged position of the remaining tert-butyl group was established by the isolation of 2-tert-butylthiophene when the disulfonic acid was hydrolyzed in presence of phosphoric acid. The identity of the tert-butylthiophene was confirmed by the properties of the aldehyde derived from it.

The sulfonation of (II) proceeded in low yield, and one of the tert-butyl groups was eliminated. The position of the remaining tert-butyl group was made clear when (III) was sulfonated. The p-toluidine salts of the two sulfonation products were identical.

It was thus shown that in the sulfonation of (II) the tert-butyl group eliminated was in the β-, not the α-position, the product being 5-tert-butyl-2-methyl-3-thiophenesulfonic acid. Whether the sulfo group entered the ring in the β-position adjacent to methyl or in that adjacent to butyl was not subjected to special investigation, but the former must be considered more probable on the basis of steric considerations.

EXPERIMENTAL

Sulfonation of 2,5-Di-tert-butylthiophene with Pyridine-bis[sulfur trioxide]. A mixture of 2.9 g (0.015 mole) of 2,5-di-tert-butylthiophene, 3.7 g (0.015 mole) of pyridine-bis[sulfur trioxide], and dichloroethane was shaken for 14 hours. The lumps that formed were periodically rubbed out. The mass was treated with 20 ml of water. A glistening precipitate of a complex compound with pyridine was formed, and this was broken down by addition of a concentrated solution containing 6.4 g of sodium carbonate. After one hour, the sodium salt of the sulfonic acid was filtered off (2.7 g). After crystallization from water and vacuum drying over phosphoric oxide at 100° to constant weight, the yield was 2.37 g (about 50%).

Found %: C 45.40; 45.56; H 6.50; 6.55; S 19.98; 19.83 Na 7.67; 7.66
$C_{12}H_{19}O_3S_2Na \cdot H_2O$. Calculated %: C 45.52; H 6.69; S 20.28; Na 7.27

Sulfonation of 2,5-Di-tert-butylthiophene with a Solution of Sulfur Trioxide in Dichloroethane. A mixture of 28.7 g of 2,5-di-tert-butylthiophene and 60 ml of dry dichloroethane was stirred at 18° for 20 minutes while 34 g (about 40% excess) of a dichloroethane solution of sulfur trioxide of about 48% strength in dichloroethane was added. After a further 40 minutes the reaction mixture was poured into 200 g of a mixture of water and ice, and the dichloroethane layer was extracted with 100 ml of water, taken in two portions. The aqueous solutions were combined, and addition of saturated sodium carbonate solution gave 37.4 g of the sodium salt of the sulfonic acid. It was recrystallized from water and dried to constant weight over phosphoric oxide in a vacuum at 100°.

Found %: C 45.7; 45.57; H 6.51; 6.57; S 20.04; 20.33; Na 7.28; 7.36
$C_{12}H_{19}O_3S_2Na \cdot H_2O$. Calculated %: C 45.52; H 6.69; S 20.28; Na 7.27

It was thus found that one molecule of water of crystallization was present in the product dried in a vacuum at 100°. In order to remove it the product was further dried to constant weight over phosphoric oxide in a vacuum at 136-140°.

Found %: S 21.40; 21.31; Na 8.16; 8.03
$C_{12}H_{19}O_3S_2Na$. Calculated %: S 21.47; Na 7.71

The yield of the anhydrous sodium salt of the sulfonic acid was about 32.7 g (75%).

p-Toluidine Salt of 2,5-Di-tert-butyl-3-thiophenesulfonic Acid. This was prepared by mixing an aqueous solution of the sodium sulfonate with a solution of p-toluidine in 2% hydrochloric acid. The yield was 70.2% and it melted at 192-193°. After recrystallization from water it formed colorless needles, m.p. 193-194°.

Found %: N 3.75; 3.71
$C_{19}H_{29}O_3S_2N$. Calculated %: N 3.65

Preparation of 2,5-Di-tert-butyl-3-thiophenesulfonyl Chloride. With water cooling, 1 g sodium 2,5-di-tert-butyl-3-thiophenesulfonate was added to 2 ml of phosphoryl chloride, and then 0.75 g of phosphorus pentachloride was added. The mixture was heated in a water bath for 30 minutes, after which the precipitate present was filtered off and the benzene solution was washed with water and dried over calcined magnesium sulfate. After removal of benzene there remained 0.7 g (about 70%) of the sulfonyl chloride, m.p. 84-89°. After three crystallizations from heptane it melted at 91-92.5°.

Found %: C 48.86; 48.89; H 6.41; 6.39
$C_{12}H_{19}S_2O_2Cl$. Calculated %: C 48.85; H 6.5

Hydrolysis of 2,5-Di-tert-butyl-3-thiophenesulfonic Acid. The sodium salt of 2,5-di-tert-butyl-3-thiophenesulfonic acid, in an amount corresponding to about 5 g of the sulfonic acid, was added to 60 ml of aqueous phosphoric acid (sp.gr. 1.633). The solution was heated to 135-140° and subjected to distillation with steam heated to the same temperature. The distillate was extracted with ether, and the extract was dried over calcined sodium sulfate. When ether was removed the product crystallized. The yield was 2.55 g (about 72%), and the product had m.p. 20-21°, b.p. 115-116° (30 mm), and n_D^{20} 1.4920.

Found %: C 73.59; 73.61; H 10.04; 10.12

$C_{12}H_{22}S$. Calculated %: C 73.40; H 10.265

The resulting di-tert-butylthiophene was brominated under the conditions necessary for the formation of 3,4-dibromo-2,5-di-tert-butylthiophene [6]. The yield of bromination product was almost quantitative. After two crystallizations from alcohol it melted at 62-63.5°. There was no melting point depression in a mixture test with 3,4-dibromo-2,5-di-tert-butylthiophene.

Sulfonation of 2,5-Di-tert-butylthiophene with a Solution of Sulfur Trioxide (in large excess) in Dichloroethane. Over a period of 90 minutes, 400 g of a freshly prepared 50% solution of SO_3 in dichloroethane (2.5 moles SO_3) was added to a cooled stirred solution of 98 g (0.5 mole) of 2,5-di-tert-butylthiophene in 200 ml of dry dichloroethane, the temperature being maintained at 18-20° during the addition and for a further 40 minutes. The reaction mixture was poured on 700 g of ice, and the dichloroethane layer was extracted with three 100-ml portions of water. The aqueous solutions were united. When saturated sodium carbonate solution was added to this solution, the sodium salt of the sulfonic acid was not precipitated. The solution was made weakly acid by addition of sodium carbonate, and the p-toluidine salt of the sulfonic acid was precipitated by the addition of a hydrochloric acid solution of p-toluidine. The product was 121 g (47%) of a substance of m.p. 224-225°. After three crystallizations from water melted at 237-238° (with decomposition).

Found %: C 51.32; 51.29; H 6.06; 5.94; S 18.86; 18.69

$C_{22}H_{32}O_6N_2S_3$. Calculated %: C 51.34 H 5.88; S 18.69

The substance obtained was therefore the di-p-toluidine salt of a mono-tert-butylthiophenedisulfonic acid.

The hydrolysis of the tert-butylthiophenedisulfonic acid was carried out in presence of phosphoric acid under conditions similar to those described above apart from the reaction temperature, which was 180-190°, the steam being superheated to the same temperature. Suitable treatment gave a product of b.p. 162-163° and n_D^{25} 1.4980, which corresponds to 2-tert-butylthiophene. The product was formylated [7], and the aldehyde isolated had b.p. 135-137° (25 mm) and n_D^{25} 1.5468; semicarbazone m.p. 215-216°; oxime m.p. 121-122°*.

Mixture tests on the corresponding derivatives of known 5-tert-butyl-2-thiophenecarboxaldehyde showed no melting point depression.

Sulfonation of 3,5-Di-tert-butyl-2-methylthiophene. Over a period of 5 minutes at 10-12°, 4.35 g (30% excess) of a dichloroethane solution of SO_3 of about 48% strength was added to a stirred solution of 4.24 g (0.02 mole) of 3,5-di-tert-butyl-2-methylthiophene in 10 ml of dry dichloroethane. The reaction mixture was then stirred for a further 40 minutes at 12-18°.

The mixture was washed with several 30-ml portions of water, and the p-toluidine salt was isolated under conditions similar to those described above. The product was 1.6 g of a substance melting at 167-181°. After recrystallization from water there remained 0.93 g (13.6%), m.p. 184.5-185.5°.

Found %: C 56.2; 56.43; H 7.01; 6.81; N 4.36; 4.28

$C_{16}H_{23}O_3NS_2$. Calculated %: C 56.27; H 6.79; N 4.102

It was thus established that the sulfo group displaced one of the tert-butyl groups.

No special investigation was made on the products contained in the dichloroethane layer.

Sulfonation of 2-tert-Butyl-5-methylthiophene. The reaction conditions were as in the preceding experiment, and the sulfonic acid was isolated in the form of its p-toluidine salt, obtained in 61.5% yield. Its melting point was 175-182°, raised to 184-185° by recrystallization from acetone. It gave no melting point depression in admixture with the p-toluidine salt prepared from the sulfonation product from 3,5-di-tert-butyl-2-methylthiophene.

SUMMARY

1. It was shown that when 2,5-di-tert-butylthiophene (I) and 2-tert-butyl-5-methylthiophene (II) were sulfonated with 1.3-1.4 molecular equivalents of sulfur trioxide, the corresponding monosulfonic acids were

* For 5-tert-butyl-2-thiophenecarboxaldehyde the literature [8] gives: oxime m.p. 86°, semicarbazone m.p. 249°.

formed. When (I) was sulfonated with 5 molecular equivalents of sulfur trioxide, one of the tert-butyl groups was eliminated and a disulfonic acid was formed.

2. In the sulfonation of 3,5-di-tert-butyl-2-methylthiophene (II) with 1.3 molecular equivalents of sulfur trioxide, a 5-tert-butyl group was eliminated, and the product was a monosulfonic acid identical with the sulfonation product from (III).

DIFFERENTIAL TITRATION OF TRIPEPTIDES AND PIPERAZINEDIONES IN THE POLYCONDENSATION PRODUCTS FROM GLYCINE ETHYL ESTER

K. T. Poroshin, T. D. Kozarenko, and Yu. I. Khurgin

In the determination of the amount of piperazinediones in the polycondensation products from glycine esters [1] and alanine esters prepared under various conditions, in a number of cases we have found it impossible to apply the "copper" method [2]. The reason for this, as spectrophotometric investigation showed, was the presence of an appreciable amount of tripeptide esters among the polycondensation products. In this connection, we found it necessary to develop a method for the separate determination of piperazinediones and tripeptides in presence of peptides of greater length.

EXPERIMENTAL

We based our method on a phenomenon that one of us had discovered previously [3]: the successive combination of peptides of different lengths with cupric ions in an alkaline medium with formation of copper "biuret" complexes. It was established that, depending on the length of the peptide, complexes of different characteristic absorption spectrum and different visual color were formed. It was shown that, as copper was added to a solution of a mixture of peptides of different lengths, "red" complexes were first formed with tetrapeptides and peptides having still longer chains (λ_{max} 510-520 mμ). Model experiments showed that "violet" complexes (λ_{max} 530 mμ) with tripeptides were formed only after the complete binding of the longer peptides by copper. Hence, in absence of dipeptides (this case is found at the later stages of the polycondensation reaction of α-amino-acid esters), the determination of the amount of tripeptides consists in measuring the amount of copper entering the complex from the "transition point" to the final end point (appearance of a slight suspension of cupric hydroxide). The transition point is the point at which the binding by copper of tetrapeptides and still longer peptides ends and the binding of tripeptides begins. The transition point can be detected visually by the appearance of a characteristic violet shade. Spectrophotometric checks showed that visual determination of the transition point can be carried out with the necessary accuracy. It is important to note that the method is applicable only to substances soluble in an alkaline medium.

As the titration with copper is carried out in an alkaline medium, it was essential to exclude the possibility of the hydrolysis of piperazinediones. For this reason the titration was carried out at room temperature in 0.1 N NaOH. Under these conditions, the piperazinediones derived from glycine and alanine are not hydrolyzed appreciably during the time required (2-3 minutes) for the titration. A longer titration time is associated with some hydrolysis of piperazinediones. At the same time it is impossible to use weaker alkali solutions for the titration, for the binding of tripeptides and longer peptides by copper is not then complete [3].

At 40° in 0.1 N NaOH, the hydrolysis of piperazinediones proceeds irrespective of the presence of copper complexes of peptides, so that the determination of the piperazinedione content can be done by the copper method in the same test sample. Hence, the procedure for separate, differential titration is as follows: a) dissolution of the test sample in not less than 100 times the amount of 0.1 N NaOH (volume for weight); b) determination of the amount of tripeptides by finding the transition point and end point of the titration with copper (for samples of 5—15 mg it is convenient to use 0.04 N $CuSO_4$); c) hydrolysis of piperazinediones in the same solution for 2-4 hours at 40° and determination of the content of anhydrides from the extra amount of copper bound after hydrolysis. Simultaneously, an alkaline solution of the polycondensation product is hydrolyzed at 40° so that the amount of piperazinediones can be determined by measuring the increase in amino nitrogen [2] by the van Slyke method. From this solution a test is taken for a repeat determination of the transition

point (verification of the stability of peptides during the alkaline hydrolysis of piperazinediones) and the determination of the total amount of copper used in the formation of "biuret" complexes with tri- and di-peptides formed during the hydrolysis of the piperazinediones. Our experiments showed good reproducibility (within ± 5%) of results in the differential titration of polycondensation products from glycine and DL-alanine ethyl esters.

The polycondensation of glycine and DL-alanine ethyl esters was carried out by the procedure described previously [4]. Carbon dioxide, dried over sulfuric acid, was used as catalyst and was added in amounts of 2 and 4 mole-% on the original amount of the ethyl ester of the amino acid. The dosage of the carbon dioxide was accurate within 1.5% of the total amount of catalyst. Reaction was at 40 ± 0.1° for 12 hours. For glycine ethyl ester the extent to which the reaction went to completion was 72% for 2 mole-% of catalyst and 80% for 4 mole-% of catalyst. The resulting polycondensation products were removed from the ampoules [4] and carefully ground three times with ether in order to remove monomer from the solid. After removal of ether in a desiccator over sulfuric acid, the products were investigated. They were readily soluble in water and in weak alkaline and acid solutions. At 160° they became dark-colored, and from 160° to 306° they melted with charring. In the polycondensation product obtained in presence of 2 mole-% of catalyst, 9.8% of tripeptides and 16.9% of piperazinediones were found by titration with copper, and by increase in amine nitrogen 17.9% of piperazinediones was found. When the reaction was carried out in presence of 4 mole-% of catalyst, 17.8% of tripeptides and 10.0% (copper method) or 12.5% (amine method) of piperazinediones were found. The proposed method can be used for investigating the composition of the polycondensation products obtained from esters of α-amino acids at various stages of the reaction.

SUMMARY

1. A method is proposed for the differential titration of polycondensation products of esters of α-amino acids.

2. The amounts of piperazinediones and tripeptides were determined among the products obtained under various conditions by the polycondensation of glycine ethyl ester.

ADDITION OF CH_3SiHCl_2 AND $C_2H_5SiHCl_2$ TO CHLORO-, CHLOROTRIFLUORO-, AND TETRAFLUORO-ETHYLENES

V. A. Ponomarenko, B. A. Sokolov, and A. D. Petrov

Very little study has been devoted to organosilicon compounds containing fluorine in an alkyl or aryl radical. This is associated with the fact that methods for the synthesis of fluoroalkyl- and fluoroaryl-silanes have not yet been adequately developed. Examination of the literature shows that there are the following general methods for the preparation of such compounds: heteroorganic [1-8], direct synthesis [9-11], the Swarts reaction [8], and copolymerization of alkenylsilanes with perfluoroolefins [12].

In a previous investigation [13] we successfully effected the additions of CH_3SiHCl_2 and $C_2H_5SiHCl_2$ to allyl and 2-methylallyl chlorides in presence of platinized charcoal:

$$CH_3SiHCl_2 + CH_2{=}CHCH_2Cl \rightarrow CH_3Si(Cl)_2CH_2CH_2CH_2Cl.$$

In view of the above mentioned application of this reaction to such fully halogenated olefins as $F_2C{=}CFCl$, and $F_2C{=}CF_2$, we may point out a new simple method for the preparation of organosilicon compounds containing fluorine in the alkyl chain. We must mention, in this connection, that in a patent by Wagner there is a passing reference to the possibility of bringing about the addition of $HSiCl_3$ to $F_2C{=}CH_2$ in presence of platinized charcoal. Also, a study of the direction of the addition of CH_3SiHCl_2 and of $C_2H_5SiHCl_2$ to chloro compounds of the vinyl type, including $CF_2{=}CFCl$, is of undoubted interest.

The addition of methyl- and ethyl-dichlorosilanes to $F_2C{=}CFCl$ was found to be considerably more difficult than the corresponding reaction with allyl chloride. The yield of addition product was 23% on the amount of CH_3SiHCl_2 or $C_2H_5SiHCl_2$ that reacted. The following peculiar features of the reaction should be noted:

1. The reaction differs from the allyl chloride reaction carried out under the same conditions in that Si-attached hydrogen is not replaced by chlorine (formation of CH_3SiCl_3 and $C_2H_5SiCl_3$), neither are the compounds $CH_3Si(Cl)_2CFHCF_2H$ and $C_2H_5Si(Cl)_2CFHCF_2H$, formed.

2. There is an appreciable side reaction in which

$CF_2{=}CFCl$ dimerizes into 
We also carried out the addition of CH_3SiHCl_2 and of $C_2H_5SiHCl_2$ to vinyl chloride. Unlike Wagner [14] in his work on the addition of $HSiCl_3$ to vinyl chloride, we could isolate only 1-chloroethyl compounds, the formation of which can be represented as follows:

$$RSiHCl_2 + ClCH{=}CH_2 \rightarrow RSi(Cl)_2CH(Cl)CH_3,$$

in which R is CH_3 or C_2H_5.

We cannot, however, exclude the possibility of the formation of β-chloroethyl compounds also; in the course of the reaction these may decompose with formation of CH_3SiCl_3 and $C_2H_5SiCl_3$ * (we isolated the latter in appreciable amount). It should be noted that the addition reactions of CH_3SiHCl_2 and of $C_2H_5SiHCl_2$ with vinyl chloride do not differ in principle, in the sense of the occurrence of side reactions [formation of CH_3SiCl_3, $C_2H_5SiCl_3$, $CH_3Si(Cl)_2C_2H_5$, $(C_2H_5)_2SiCl_2$], from the reactions of the same compounds with allyl chloride [13].

The main difference is in the direction of addition: whereas the $RSiCl_2$ residue adds to allyl chloride at the most highly hydrogenated carbon atom, the reverse occurs with vinyl chloride. The proof of this, however, was rendered difficult by the thermal instability of the β-chloro compounds that could possibly be formed. As the addition products formed by CH_3SiHCl_2 and by $C_2H_5SiHCl_2$ with $F_2C{=}CFCl$ have lower boiling points than $CH_3Si(Cl)_2CH(Cl)CH_3$ and $C_2H_5Si(Cl)_2CH(Cl)CH_3$, they must be assigned the structure of α-chloro-compounds, $CH_3Si(Cl)_2CF(Cl)CF_2H$ and $C_2H_5Si(Cl)_2CF(Cl)CF_2H$, since the corresponding β-chloro compounds should have higher boiling points. Under the above-described conditions, CH_3SiHCl_2 and $C_2H_5SiHCl_2$ add also to tetrafluoroethylene.

EXPERIMENTAL

$CH_3Si(Cl)_2CF(Cl)CF_2H$. A mixture of 115 g of dichloromethylsilane, 110 g of $F_2C{=}CFCl$, and 0.3 g of platinized charcoal (1% Pt) was prepared in an autoclave and heated at 160° for 15 hours. At this temperature the pressure rose to 30 atm and then fell to 20 atm. Fractionation of 163 g of the mixture of reaction products through a 35-plate column gave: 1) 93.5 g of unchanged CH_3SiHCl_2, b.p. 40°, 2) 23 g of $F_2C{=}CFCl$, b.p. 57-58° (734 mm), and 3) 10 g (23% on the amount of CH_3SiHCl_2 that reacted) of $CH_3SiH(Cl)_2CF(Cl)CF_2H$: b.p. 124.5° (734 mm); d_4^{20} 1.4211; n_D^{20} 1.4000; found MR 39.49; calculated MR 39.10

Found %: C 16.71; 16.57; H 2.11; 2.06
$C_3H_4Cl_3F_3Si$. Calculated %: C 16.94; H 1.88

Owing to the presence of Si and Cl in the molecule, analysis for fluorine was difficult and somewhat high results were obtained (Found 28.61% F, Calculated 24.63% F).

$C_2H_5Si(Cl)_2CF(Cl)CF_2H$. A mixture of 130 g of dichloroethylsilane, 170 g of $F_2C{=}CFCl$, and 0.3 g of platinized charcoal under an initial pressure of nitrogen of 25 atm was heated at 160° for 15 hours; the maximum pressure at this temperature was 75 atm. The mixture of reaction products (226 g) was twice fractionated through a 35-plate column and gave 1) 52.6 g of $\begin{matrix} F_2C{-}CFCl \\ | \\ F_2C{-}CFCl \end{matrix}$, b.p. 58° (754 mm), 2) 87.2 g of unchanged $C_2H_5SiHCl_2$, b.p. 74.5° (755 mm), 3) 18.4 g (23% on the amount of $C_2H_5SiHCl_2$ that reacted) of $C_2H_5Si(Cl)_2CF(Cl)CF_2H$: b.p. 154° (754 mm), d_4^{20} 1.4170, n_D^{20} 1.4120; found MR 43.11; calculated MR 43.61.

Found %: C 19.69; 19.88; H 2.26; 2.42
$C_4H_4Cl_3F_3Si$. Calculated %: C 19.57; H 2.50

$CH_3Si(Cl)_2CH(Cl)CH_3$. This was prepared from 102 g of CH_3SiHCl_2 and 108 g of $CH_2{=}CHCl$, which were heated in an autoclave for six hours at 150-160° and 25-30 atm in presence of 0.5 g of platinized charcoal. Fractionation of 119 g of product through a 35-plate column gave:

1. 27 g of CH_3SiHCl_2, b. p. 40.5° (747 mm).

* The formation of CH_3SiCl_3 and $C_2H_5SiCl_3$ can be represented also in another way, for example $RSiHCl_2 + ClCH_2CH_2Si(Cl)_2R \rightarrow RSiCl_3 + CH_3CH_2Si(Cl)_2R$.

1. 16.4 g of CH_3SiCl_3: b.p. 35° (747 mm).

3. 12.7 g of $CH_3Si(Cl)_2C_2H_5$: b.p. 100° (747 mm); d_4^{20} 1.0630, n_D^{20} 1.4197; Found MR 34.04; Calculated MR 34.17.

4. 12 g (7%) of $CH_3Si(Cl)_2CH(Cl)CH_3$: b.p. 134° (741 mm); d_4^{20} 1.2170; n_D^{20} 1.4480; Found MR 39.12; Calculated MR 39.01. The literature [15] gives b.p. 136°.

$C_2H_5Si(Cl)_2CH(Cl)CH_3$. This was prepared from 130 g of $C_2H_5SiHCl_2$ and 117 g of CH_3CHCl, which were heated in an autoclave for 14 hours at 160-165° and 25 atm in presence of 0.4 g of platinized charcoal. Two fractionations of 210 g of reaction products through a 35-plate column gave 1) 8.7 g of $C_2H_5SiHCl_2$, b.p. 74-75° (765 mm), 2) 52 g of $C_2H_5SiCl_3$, b.p. 98° (765 mm), 3) 38 g of $(C_2H_5)_2SiCl_2$, b.p. 129.8° (765 mm), 4) 25 g (13%) of $C_2H_5Si(Cl)_2CH(Cl)CH_3$, b.p. 161° (730 mm), d_4^{20} 1.1970, n_D^{20} 1.4575; Found MR 43.62; Calculated MR 43.64. The literature [16] gives b.p. 41.5° (9 mm); d_4^{20} 1.2017, n_D^{20} 1.4578.

$CH_3Si(Cl)_2CF_2CF_2H$. This was prepared under the same conditions. The yield was 13.9 g (15% on the amount of CH_3SiHCl_2 that reacted), and it had b.p. 95.2° (753 mm); d_4^{20} 1.3879; n_D^{20} 1.3689; Found MR 34.95; Calculated MR 34.29.

$C_2H_5Si(Cl)_2CF_2CF_2H$. The yield of this substance was 12.2 g (20% on the amount of $C_2H_5SiHCl_2$ that reacted), and it had b.p. 119.7° (748 mm); d_4^{20} 1.3527; n_D^{20} 1.3819; Found MR 39.40; Calculated MR 38.80.

SUMMARY

1. The addition of CH_3SiHCl_2 and of $C_2H_5SiHCl_2$ to $F_2C=CF_2Cl$, $CH_2=CHCl$ and $F_2C=CF_2$ in presence of platinized charcoal was effected for the first time.

2. An investigation was made into the direction of addition of CH_3SiHCl_2 and of $C_2H_5SiHCl_2$ to $F_2C=CFCl$ and $CH_2=CHCl$ under these conditions.

REACTIONS OF TRICHLOROSILANE AND DICHLOROMETHYLSILANE WITH BENZENE

E. A. Chernyshev and A. D. Petrov

A very interesting reaction of silanes containing silicon-attached hydrogen is their addition to unsaturated compounds. This reaction can be initiated by ultraviolet radiation [1], peroxides [1], Friedel-Crafts catalysts [2], platinized charcoal [3], and other agents. Of no less interest is the recently studied reaction of silanes of this type with compounds containing active hydrogen (acids, alcohols, amines, etc. [4-6]). These last reactions proceed with the elimination of hydrogen, for example:

$$R_3SiH + R'OH \rightarrow R_3SiOR' + H_2$$

No papers have been published on the reaction of silanes containing silicon-attached hydrogen with aromatic hydrocarbons, and we are aware only of some short references in patents [7-9] to this reaction.

In the present investigation we have studied the reactions of trichlorosilane $HSiCl_3$ and dichloromethylsilane CH_3SiHCl_2 with benzene. The reactions were carried out in an autoclave at high temperature. In absence of catalyst no reaction was observed between these compounds at temperatures of up to 300°. When palladized or platinized charcoal was used as catalyst (temperature in experiments 270-300°), only traces of reaction products were isolated. Successful results were obtained when Raney nickel and aluminum chloride were used as catalysts. When benzene reacted over Raney nickel with trichlorosilane and with dichloromethylsilane, trichlorophenylsilane and dichloromethylphenylsilane were obtained in yields of 24% and about 18% respectively. With aluminum chloride the yields of trichlorophenylsilane and dichloromethylphenylsilane were 32% and 23% respectively. All of the products were methylated, and the Raman spectra of the resulting trimethylphenylsilanes were determined. The results showed that the products were aromatic silahydrocarbons, not containing any hydrogenated forms as impurity. The reactions, therefore, proceed as follows:

EXPERIMENTAL

1. Reaction of Trichlorosilane with Benzene in Presence of Nickel. A mixture of 268 g of trichlorosilane, 156 g of benzene, and 10 g of Raney nickel was prepared in a one-liter rotating steel autoclave, which was heated at 300° for 12 hours. After the autoclave had cooled, the pressure was 45 atm. Nickel was filtered off, and the reaction product was fractionated through a 30-plate column. The following fractions were collected: Fraction I, $HSiCl_3$, b.p. 31-33° (743 mm), 73.5 g; Fraction II, $SiCl_4$, b.p. 55-57° (734 mm), 51.5 g; Fraction III, C_6H_6, b.p. 79-80° (743 mm), 123.7 g; Fraction IV, 73.4 g of trichlorophenylsilane, b.p. 195-196° (743 mm); n_D^{20} 1.5222; d_4^{20} 1.3144; Found MR 48.74; Calculated MR 48.84. Yield on the amount of trichlorosilane that reacted, 24%.

2. Reaction of Dichloromethylsilane with Benzene in Presence of Nickel. The substances taken were dichloromethylsilane (228 g), benzene (156 g), and nickel (10 g). The reaction conditions were as indicated above. The pressure in the autoclave before unloading was 50 atm. Fractionation gave: Fraction I, CH_3SiHCl_2, b.p. 41-42° (749 mm), 54.3 g; Fraction II, CH_3SiCl_3, b.p. 64.5-65° (749 mm), 53.5 g; Fraction III, $(CH_3)_2SiCl_2$, b.p. 70-71° (749 mm), 18.3 g; Fraction IV, C_6H_6, b.p. 79.5-80.5° (749 mm), 128.5 g; Fraction V, 51.3 g of dichloromethylphenylsilane, b.p. 203.5-204° (749 mm); n_D^{20} 1.5175; d_4^{20} 1.1824; Found MR 48.45; Calculated MR 49.21. Yield on the amount of dichloromethylsilane that reacted, 17.7%. Residue, 6.8 g.

3. Reaction of Trichlorosilane with Benzene in Presence of Aluminum Chloride. A mixture of 268 g of trichlorosilane, 156 g of benzene, and 10 g of aluminum chloride was prepared in a one-liter rotating steel autoclave, which was heated at 300° for 12 hours. After the autoclave had cooled, the pressure was 50 atm. The autoclave was opened, 5 g of sodium chloride was added, and the mixture was heated at 100° for one hour. When the autoclave was cool it was unloaded; the $AlCl_3 \cdot NaCl$ complex was filtered off, and the product was fractionated, the fractions collected being: Fraction I, $HSiCl_3$, b.p. 30-33°, 85 g; Fraction II, $SiCl_4$, b.p. 56-57° (740 mm), 38.4 g; Fraction III, C_6H_6, b.p. 79-80° (740 mm), 125.4 g; Fraction IV, 87.3 g of trichlorophenylsilane, b.p. 195-195.5° (740 mm); n_D^{20} 1.5232; d_4^{20} 1.3148; Found MR 48.81; Calculated MR 48.84. Yield on the amount of trichlorosilane that reacted, 32%. Residue, 8.3 g.

4. Reaction of Dichloromethylsilane with Benzene in Presence of Aluminum Chloride. The substances taken were dichloromethylsilane (228 g), benzene (156 g), and aluminum chloride (10 g). Reaction conditions were as in Experiment 3. Before the addition of sodium chloride the pressure in the autoclave was 55 atm. Fractionation gave: Fraction I, CH_3SiHCl_2, b.p. 41-42° (748 mm), 25.3 g; Fraction II, CH_3SiCl_3, b.p. 65-66° (748 mm), 62.4 g; Fraction III, $(CH_3)_2SiCl_2$, b.p. 70-71° (748 mm), 32.4 g; Fraction IV, C_6H_6, b.p. 79.5-80° (748 mm), 125.3 g; Fraction V, 78.8 g of dichloromethylphenylsilane, b.p. 203-204° (742 mm); n_D^{20} 1.5182; d_4^{20} 1.1832; Found MR 48.68; Calculated MR 49.21. Yield on the amount of dichloromethylsilane that reacted, 23%. Residue, 40 g; this distilled over a wide range of temperature, 120-206° (12 mm).

The spectrum analysis was carried out by Yu. P. Egorov, to whom we express our thanks.

SUMMARY

It was shown that trichlorosilane and dichloromethylsilane react with benzene when heated in presence of nickel or aluminum chloride with formation of hydrogen together with trichlorophenylsilane and dichloromethylphenylsilane, respectively.

SYNTHESIS AND REACTIONS OF OXYGEN-CONTAINING ORGANOSILICON COMPOUNDS

COMMUNICATION 3. REACTION OF PROPYLENE OXIDE WITH ALKYL- AND ARYL-CHLOROSILANES

M. F. Shostakovsky, M. S. Malinovsky, M. K. Romantsevich, and D. A. Kochkin

The reactions between olefin oxides and halogen-containing organosilicon compounds have not received adequate study. The most complete study has been made of the condensations of ethylene oxide [1-3], and, as a result, new oxygen-containing organosilicon compounds have been prepared in accordance with the general scheme:

$$R_nSiCl_{4-n} + (4-n)\ H_2C\!-\!CH_2 \;(O) \longrightarrow R_nSi(OCH_2CH_2Cl)_{4-n}$$

Other epoxides that have been brought into reaction with halogen-containing organosilicon compounds are epichlorohydrin and glycidol [4], which react in accordance with the following equations:

$$R_nSiCl_{4-n} + (4-n)\ H_2C\!-\!CH\cdot CH_2Cl \;(O) \longrightarrow R_nSi(OCH_2CHClCH_2Cl)_{4-n}$$

$$R_nSiCl_{4-n} + (4-n)\ H_2C\!-\!CH\cdot CH_2OH \;(O) \longrightarrow R_nSi(OCH_2CHClCH_2OH)_{4-n},$$

from which it follows that the epoxy ring of these compounds is broken on the side of the primary carbon atom.

With the object of obtaining further information on the position in which the epoxy ring opens, we undertook the present investigation, in which we describe the preparation of (2-chloropropoxy)ethyldichlorosilane, bis(2-chloropropoxy)methylsilane, bis(2-chloropropoxy)dimethylsilane, bis(2-chloropropoxy)ethylsilane, and tris(2-chloropropoxy)vinylsilane from propylene oxide and the corresponding alkylchlorosilanes. Our experiments showed that the α-epoxy ring in propylene oxide is opened on the primary-carbon side. This was confirmed by nitric acid oxidation of the hydrolysis products of the above esters. One of the hydrolysis products was a chloropropanol, which was oxidized to 2-chloropropionic acid, showing that the hydrolysis product was in fact 2-chloro-1-propanol and therefore that the epoxy ring of propylene oxide had opened on the primary-carbon side.

Hence, reaction between propylene oxide and alkyl- and aryl-chlorosilanes can be represented as follows:

$$R_nSiCl_{4-n} + (4-n)\ H_2C\!-\!CH_2\cdot CH_3 \;(O) \longrightarrow R_nSi(OCH_2CHClCH_3)_{4-n}.$$

in which R is alkyl or aryl.

The resulting (2-chloropropoxy) silanes are mobile liquids having a feeble ethereal odor. They can be vacuum-distilled without decomposition. They are soluble in ether, alcohol, and other organic solvents. Some physico-chemical properties of these compounds are given in the table.

EXPERIMENTAL

1. Preparation of (2-Chloropropoxy) ethylisobutylsilane. Propylene oxide (29.04 g, i.e. 0.5 mole) was placed in a three-necked round-bottomed flask fitted with mechanical stirrer, thermometer, dropping funnel, and reflux condenser. Chloroethylisobutylsilane (75.36 g, i.e. 0.5 mole) was added from the dropping funnel at such a rate that the temperature of the reaction mixture did not rise above 30-35°. When the whole of the chlorosilane had been added, the reaction mixture was heated at 35-45° for eight hours and was then set aside overnight at room temperature. Repeated distillation of the reaction products gave 38.6 g (84.9%) of (2-chloropropoxy) ethylisobutylsilane (for constants see table). The other alkyl (2-chloropropoxy) silanes were prepared similarly.

2. Hydrolysis of Bis (2-chloropropoxy)ethylsilane. A mixture of 49.5 g (0.2 mole) of bis (2-chloropropoxy)ethylsilane and 80 ml of nitric acid (sp.gr. 1.4) was prepared in an Erlenmeyer flask. After the mixture had been shaken vigorously, it became warm, copious gas evolution occurred, and a gelatinous precipitate formed. The flask was then warmed in a water bath at 40-50° for one hour in order to complete reaction. In order to remove nitric acid, 250 ml of water and 40 ml of concentrated hydrochloric acid were added. The liquid was separated from the gelati-

hour precipitate and distilled. A fraction of b.p. 184-185° (753 mm) was separated. It corresponded in properties to 2-chloropropionic acid, which would result from the oxidation of 2-chloro-1-propanol. The properties found for the fraction were: b.p. 184-185° (753 mm); d^{20} 1.3858; d_4^{20} 1.379; n_D^{20} 1.4815; MR 22.36; calculated $C_3H_5O_2Cl$ MR 22.41. For $CH_3CHClCOOH$ the literature [5] gives b.p. 185°, d^{20} 1.398.

SUMMARY

1. The reactions between propylene oxide and the following alkylchlorosilanes were investigated: chloroethylisobutylsilane, dichloromethylsilane, dichlorodimethylsilane, dichloroethylsilane, and trichlorovinylsilane.

2. The following compounds were prepared and characterized for the first time: (2-chloropropoxy) ethylisobutylsilane, bis(2-chloropropoxy)methylsilane, bis(2-chloropropoxy)dimethylsilane, bis(2-chloropropoxy)ethylsilane, and tris(2-chloropropoxy)vinylsilane.

3. When propylene oxide reacts with chloro organosilanes, its epoxy ring is broken on the side containing the primary carbon atom.

4. The proposed method may be a general one for the preparation of various alkyl- and aryl-(2-halopropoxy)silanes from propylene oxide and various alkyl- and aryl-chlorosilanes.

CHRONICLE

HUNGARIAN CHEMICAL CONGRESS

The Second Hungarian Chemical Congress was held in Budapest at the end of November, 1955. It was organized by the Hungarian Chemical Society, which was established 1907 and has about five thousand members. In this work the Society was assisted by the Division of Chemical Sciences of the Academy of Sciences of the Hungarian People's Republic. A delegation from the Academy of Sciences of the USSR took part in the work of the Congress; it consisted of V. I. Spitsyn, Corr. Member Acad. Sci. USSR (leader of delegation), A. F. Kapustinsky, Corr. Member Acad. Sci. USSR, and V. V. Koziov, Doctor Chem. Sci.

The work of the Second Hungarian Chemical Congress began on November 17 in the large conference hall of the Academy of Sciences of the Hungarian People's Republic. The Congress opened with a plenary session, which was addressed by G. Szabo*, Assistant Minister for the Chemical Industry of the Hungarian People's Republic and President of the Hungarian Chemical Society. In discussing the problems facing Hungarian chemists, he stated that the great rise in production in Hungarian industry was quantitative rather than qualitative; it was essential to improve the methods of production, to intensify automation, and to fulfil the chemical requirements of the country more completely. The utilization of coal and petroleum remained the main objectives of chemical industry. In the Second Five-Year Plan, such branches of chemical industry as the manufacture of plastics based on vinyl chloride and of synthetic fibers of the 6- and 6,6-nylon types must be established in the Hungarian People's Republic. The production of synthetic liquid fuel, insecticides, fertilizers, and various pharmaceutical products must also be greatly extended. Apart from the organization of new branches of industry, the existing undertakings must be reorganized and rationalized on a higher technical level. It is necessary to turn attention on the introduction of the complexing method of treating Hungarian bauxites, on the manufacture of valuable aluminum alloys, on anticorrosion measures for metals, etc.

G. Szabo stated that, in the period that had elapsed since the First Hungarian Chemical Congress in 1951, chemistry had made significant progress in Hungary and had made its contribution to the development of industry. The speaker referred to the considerable assistance that Hungarian chemistry had received from the USSR and from all of the People's Democracies.

Academician E. Schulek addressed the assembly on the part played by the Division of Chemical Sciences of the Academy of Sciences of the Hungarian People's Republic in the development of chemistry in Hungary, and the sectional sessions of the Congress then began. These were held simultaneously over a period of four days (November 17, 18, 19, and 20), the sections being: inorganic, analytical, and physical chemistry, organic chemistry, and technology. The Congress was attended by about five hundred Hungarian chemists and by chemists from China, the German Democratic Republic, France, Poland, Czechoslovakia, Rumania, Yugoslavia, the German Federal Republic, and other countries. About fifty papers were presented at the Congress by Hungarian chemists, and nineteen by foreign chemists. Many interesting communications were made by Hungarian chemists.

Academician G. Schay summarized the work carried out since 1949 by his team of workers at the Budapest Technical University and the Academy of Sciences of the Hungarian People's Republic (J. Halasz, F. Nad, D. Szekey, and Szeny Endrenei). In order to elucidate the state of the adsorbed phase and the nature of the

* The spellings of most of the Hungarian names, which appear in the original in Russian transcription, have been checked, but there may be a few errors. – Publisher.

forces acting at interfaces, various new experimental methods were developed, in particular a gravimetic method that enables the adsorption process to be followed autographically in the form of a curve for change in weight against time. This method, in spite of the fact that an analytical balance is used instead of a McBain spring balance, was found to be both simpler and more sensitive than the usual method. Another method proposed uses a floating vessel, the upper part of which contains a dish holding the sorbent, so that the course of the process can be recorded from the extent of immersion of the "float" in accordance with Archimedes' principle. Finally, a dynamic method was developed, this being particularly suitable for the measurement of adsorption rates from a stream. This work enabled these workers to establish a simple formula for calculating the volume of a substance (Vn) necessary for the formation of a unimolecular layer on the surface of the adsorbent, knowing the adsorption volume V and the ratio of the equilibrium pressure to the original pressure p/ po:

$$V_n = V\left(1 - \frac{p}{p_0}\right),$$

A relationship was established also between the differential heat of adsorption and the heat of evaporation of the sorbate; it was related also to the saturated vapor pressure curve of the sorbate. By the application of the methods of statistical physics, it was shown that the Langmuir adsorption isotherm is not necessarily associated with the localization of adsorption at discrete sites.

Academician E. Schulek (coworkers E. Pungor and J. Trompler) described a newly developed method of titrometric gas analysis. The apparatus that they have designed enables test samples to be taken rapidly and simultaneously from gas and liquid phases with the object of making subsequent microchemical volumetric analyses on these samples. In order to standardize the method, known mixtures of ethanol and methanol were taken. A further study of mixtures of these alcohols with water made it possible to make an analysis of the departures of these systems from Raoult's law. It was suggested that the observed departures of these actual systems from the ideal laws for solutions are to be explained by the chemical peculiarities of the structure of the liquid phases.

Academician L. Erley, in conjunction with his coworkers of the Budapest Technical University, E. Banyai, D. Rady, and E. Zalay, read several papers on the synthesis and applications of several redox indicators of the Variamine blue type. They have prepared new derivatives of Variamine blue with sulfanilide, sulfanisidide, etc., and they have prepared also nucleus-substituted Variamines. A study of their oxidation processes, in which simultaneous measurements of the redox potential were made, enabled them to establish the mechanism of these reactions and its dependence on pH. The authors have successfully applied an acetic acid solution of ascorbic acid for redox titrations, and have in this way determined elementary bromine, bivalent mercury, quadrivalent lead, sexavalent chromium, etc.

Academician A. Buzagh (Budapest Scientific University) read a paper on the effect of freezing on the properties of colloids. In the freezing and subsequent thawing of sols, either there is no change, or coagulation occurs. When coagulation occurs, it may be reversible or irreversible, depending on the experimental conditions (nature and concentration of the sol, rate and degree of cooling). The character of the coagulation depends on the agglomeration of particles and on adhesion phenomena. In this connection the speaker pointed out the applicability of the Ostwald-Buzagh theory of continuity in cases in which the stability of the sol changes after being frozen. Under certain conditions, the freezing of gels promotes peptization, and in some cases it also brings about disaggregation. The speaker explained this phenomenon by the formation of a lyosphere in the colloidal particles. On the basis of the experimental data he examined the effect of water contained in the gel on the peptization process.

Some interesting papers were presented on organic chemistry. Academician V. Bruckner and J. Kovacs (Budapest Scientific University) described their results on the synthesis of the polypeptide γ-poly-a-glutamic acid (molecular weight 9000):

For the synthesis of a polyglutamic acid having α- and γ-glutamic links, the latter predominating, the authors' method of α-ω transpeptidation was used, the substances being converted into their copper complexes to avoid racemization. The substance synthesized corresponded in properties to natural α-polyglutamic acid isolated from the culture medium of Bac. Subtilis (Bac. anthracis).

L. Mester (Budapest Technical University) gave a report on his work on new nitrogen-containing sugar derivatives, (formazans of sugars, phenylhydrazides of thioaldonic acids, etc.). The formazan reaction, which was discovered in 1951 by the author and another Hungarian chemist, G. Zemplén, consists in the treatment of a carbohydrate first with phenilhydrazine and then with aniline diazotized in pyridine; it is widely used, both for simple carbohydrates, and also for the periodic acid oxidation products of various polysaccharides (cellulose, dextrin, insulin, etc.). The formazans obtained were separated by paper chromatography. In many cases the phenylhydrazones were proved to have the aldehyde structure. Only aldehyde phenylhydrazones with an open chain take part in this reaction; ketoses do not form formazans.

L. Vargha (Budapest Pharmacy Research Institute) reported on the synthesis of new carbohydrate derivatives having a cytostatic action. Carbohydrate derivatives containing ethylenimino, 2-chloroethylenimino, and bis-(2-chloroethyl)amino groups were studied. The following compounds were synthesized: 6-deoxy-6-ethylenimino-1,2-isopropylidene-α-glucofuranose ($C_{11}H_{19}O_5N$, m.p. 131-132°), 1,6-dideoxy-1,6-bisethylenimino-3,4--isopropylidene-D-mannitol ($C_{13}H_{24}O_4N_2$), 1,6-bis(2-chloroethylamino)-1,6-dideoxy-D-mannitol dihydrochloride ($C_{18}H_{22}O_4N_2Cl_4 \cdot 2HCl$, m.p. 240-241°), 2-chloroethyl)-D-gluconamide ($C_8H_{17}O_6NCl$, m.p. 144-145°), 2-chloroethylamide of D-glucosaccharic acid ($C_{16}H_{18}O_6N_2Cl_2$, m.p. 172-174°), and others. It was shown that some of these substances have a marked cytostatic action and are of interest as effective anti-cancer agents.

J. Kiss (Sopron Forestry Institute) described the results of investigations on the stereochemistry of amino alcohols and, in particular, of sphingosine, which may be isolated from the nerve tissues of animals. He synthesized sphingosine from the D-erythro-1-amino-2,3-dihydroxylactone of butyric acid; it was found to be identical with the natural product, which has the structure D-erythro-2-amino-trans-4-octadene-1,3-diol. It was established that in natural sphingolactosides such as phrenosine and kerasine the galactose is bound in the α-positions. The author synthesized also 2n-phrenosine and 2n-kerasine, identical with the products isolated from natural sphingolactosides, by the reduction of nervone and oxynervone.

The papers presented at the technological section of the Congress concerned the technology of fertilizers, the treatment of Hungarian bauxites, the electrolytic precipitation of gallium from solutions obtained by the treatment of the bauxites, calculations on continuous columns for the partial oxidation of methane, preparation of high-quality lubrication oils, etc.

Considerable interest was shown in the paper of D. Turzo and L. Kovacs (Synthetic Fibers Research Institute, Budapest) on the preparation of vinyl chloride from gases formed by the partial oxidation of methane. Working independently of the work of Linn and Kobe, which was published in 1954, and working also under different conditions, they used a gas mixture of the composition: C_2H_2 – 8%; H_2 – 53%; CO – 25%; CH_4 – 3%; CO_2 – 2%; HCl – 9%. On the catalyst selected, which worked for more than 300 hours without being in the slightest degree poisoned, there was a 99-100% conversion of acetylene into vinyl chloride.

Academician G. Fodor (Szeged University), in conjunction with L. Berögy and F. Kallai (Organic Chemistry Research Institute, Budapest), presented a paper on the progress made by Hungarian chemists in the chemistry of furan. The main lines of work have been: 1) hydrogenation of 2-furaldehyde at atmospheric pressure over a modified Adkins catalyst with formation of furfuryl alcohol, methylfuran, and tetrahydromethylfuran; 2) oxida-

tion of 2-furaldehyde to 2-furoic acid and the conversion of the latter into furan; 3) preparation of aliphatic compounds by the hydrolytic oxidation of the 2-furaldehyde ring - thus chlorobutanol, dichlorobutane, chloropentanols, dichloropentane, and other substances were obtained, but it was found difficult to prepare chloro alcohols owing to the reversibility of the reaction:

Academician M. Freund, J. Batory, and M. Erdi (Veszprem Petroleum and Gas Institute) reported on the method of deparaffination of petroleum products by extractive crystallization of the urea derivatives. In addition to normal paraffins, components having naphthene and aromatic character are also separated. In the treatment of light, predominantly paraffin, distillates, these are diluted with 4-methyl-2-pentanone, and the urea derivative is obtained with the aid of saturated aqueous urea. The adduct is also decomposed with aqueous urea. In the separation of ceresin it is desirable to use solid urea in presence of an acetone wetter. The method has been checked under industrial conditions.

The members of the Soviet delegation read papers at the appropriate sections of the Congress. V. I. Spitsyn, Corr. Member Acad. Sci. USSR, gave a paper on "The Application of Labeled Atoms in the Investigation of the Chemistry of Complex Compounds", A. F. Kapustinsky, Corr. Member Acad. Sci. USSR, read a paper on "The Thermal Capacity of Ions in Aqueous Solution", and V. V. Kozlov, Doctor Chem. Sci., read a paper on "The Photosensitivity of Selenium-containing Nitro Compounds".

The participation in the Congress was extremely active. As a rule, the presentation of the papers was followed by a lively informal discussion. At the end of the Congress there was a short plenary session at which some concluding remarks were made by the Vice-President of the Hungarian Chemical Society, Academician G. Fodor.

The papers given by the Hungarian chemists showed that chemical research work is carried out in Hungary in a considerable number of scientific institutes and at a high scientific level. Many modern methods of investigation (various physical and physicochemical methods of analysis, thermogravimetry, paper chromatography, microchemical methods, spectroscopic and X-ray structure investigations) are used in these researches. However, radioactive and stable isotopes are scarcely used, the use of infrared spectroscopy is not extensive, and there are no investigations on electron microscopy and electron diffraction.

The investigations of Hungarian chemists are to a considerable degree concentrated on processes for the treatment of natural native raw material (coal, bauxite, petroleum). In these fields they have made great progress during the last five years. It is necessary to take account of the fact that Hungarian research laboratories were almost completely out of action during the war. They have now been reestablished, and many new scientific institutes have been built. The large number of young participants was notable at the Congress (almost one-third of the total number). Many young Hungarian specialist chemists have been trained recently, some of them in the USSR.

From observation of the work of the Congress it may be concluded that Hungarian scientists have adequate contacts with the scientists of other countries, as is evident from the large number of papers given by foreign delegates at the Congress.

Owing to the shortness of our visit to Hungary, our delegation could examine only a few of the scientific establishments. In Budapest we visited various departments (institutes, as they call them in Hungary) of the Etvös Scientific University (which corresponds to our university), the Technical University (which corresponds to our higher technical school), and the Institute of Organic Technology of the Ministry of Chemical Industry. In Veszprem we visited the Chemical University and Petroleum and Gas Research Institute. In Szeged we visited some departments of the chemistry school of the university. The delegation also visited the Tungsram works in Budapest, and there saw the manufacture of the rare metals tungsten and molybdenum and of various electrotechnical and radiotechnical goods.

The laboratories that we examined in the higher educational establishments of Hungary impressed us favorably with respect to the working space, the amount and quality of the equipment, and the number and qualifications of the teachers. It should be noted that the Hungarian higher educational establishments, particularly those in Budapest, were almost completely out of action during the war. They have now been reestablished on a present-day scientific and technical level and on a very much greater scale than in the prewar period.

We must mention also a characteristic feature of the training of chemist in Hungary: the general chemical educations of pure chemists and of applied chemists do not differ essentially in their scope. Specialization begins only from the ninth term, and technologists and chemists trained in Hungary have therefore a very broad general basis of knowledge. The training of a technologist or chemist is generally completed by scientific work for a diploma.

Much scientific research work is carried out in the higher educational establishments that we visited. The quality of this research is in accordance with the highest requirements of modern science; it is carried out with equipment manufactured in Hungary, the USSR, Czechoslovakia, and other countries. The departments are well staffed and have plenty of laboratory space. For the purposes of illustration we may take the Department of Inorganic Chemistry of Budapest University, which is directed by Professor J. Prost: there are 23 teachers and a staff of 35 altogether, including mechanics and glassblowers; the effective working space in the department is 1400 sq.m. (14 laboratory rooms) for a total of only 180 chemical students. It is noteworthy that in Veszprem Chemical University there is a separate building for pilot-scale trials on chemical processes. Such favorable conditions are promising for the future of the development of chemistry in Hungary.

We will now give a brief indication of the lines of work going on in the Hungarian chemical institutes with which we were able to acquaint ourselves. These, of course, are only a few of the Hungarian laboratories in which chemical investigations are being carried out.

The Department of General Chemistry at the Etvös Scientific University (Budapest) is directed by Professor B. Lendiel. Inorganic glasses are being studied in this department from the point of view of their use for the construction of glass electrodes (dependence of the electrochemical properties of the glasses on their compositions, the conditions under which they were prepared, etc.). Another line of work is the synthesis of biuret complexes of metals and the determination of their physicochemical constants. Investigations are being carried out also in connection with the establishment of a silicone industry in Hungary. In particular, the following reaction, which is of interest for the preparation of silicones, is being studied:

$$SiCl_4 + CH_3AlCl_2 \longrightarrow AlCl_3 + CH_3SiCl_3.$$

The Department of Analytical Chemistry is directed by Academician E. Schulek, who is working on the application of physicochemical methods in chemical analysis. The Department of Physical Chemistry is directed by Academician T. Erdey-Gruz. In collaboration with Academician G. Schay, he has written a textbook in two volumes for scientific and technical universities which covers the course in physical chemistry, taking into account the most recent developments. Research on electrochemisty is being carried out in the department (study of overvoltage and other matters related to the mechanism of electrode processes). The Department of the Chemistry and Technology of Colloids is directed by Academician A. Buzagh. For some years now he has been studying phenomena associated with the formation and breakdown of colloid systems and the extension of the practical application of colloid chemistry. The Department of Organic Chemistry of the Scientific University is directed by Academician V. Bruckner, who is studying the structure of natural polypeptides and developing methods for their synthesis.

In the Budapest Technical University, the Department of Inorganic Chemistry is directed by Professor J. Prost, who is carrying out investigations in electrochemistry (polarography, coulometric analysis, electroendosmosis, electrochemical kinetics of coarsely dispersed systems); he has perfected a technique of polarographic analysis. In this department studies are being made also of methods for preparing silicones, and a physicochemical investigation is being made into the behavior of binary mixtures.

The Department of General and Analytical Chemistry is directed by Academician L. Erdey, who is a specialist in inorganic and analytical chemistry and is carrying out investigations along various lines. He has designed an interesting apparatus for thermogravimetry and developed original methods of fluorescence titration. He is studying new indicators for redox titrations.

In the Budapest Technical University there is a combined department of physical chemistry and physics, which is directed by Academician G. Schay. Investigations are going on here on the mechanism of physical adsorption. The techniques of infrared and Raman spectroscopy, as applied to the determination of the structure of chemical compounds, are in the process of being introduced and assimilated. The Department of Organic Chemistry is directed by Professor G. Zemplen. Investigations are being carried out here on natural glycosides. Methods for their synthesis are being developed, particularly for glucosides of the benzalcoumarone group. Nitrogen-containing carbohydrate derivatives are being studied, particularly formazan derivatives. Professor D. Becke is working on the synthesis of physiologically active substances, for example adrenalin, and on the establishment of the structures of alkaloids, in particular cotarnine.

A large center of chemical research in Hungary is the Chemistry School of Szeged University. The Department of Inorganic and Analytical Chemistry is directed by Professor Z. Szabo, who is conducting several lines of investigation: kinetics of gas reactions, namely, the first stages in the oxidation of hydrocarbons; catalytic methods in analytical chemistry; and the use of complex compounds in analytical chemistry. Recently, an investigation of reactions with the aid of magnetic methods has begun. Z. Szabo is interested also in questions associated with the relationship of the properties of elements with their positions in the periodic system.

The Department of Organic Chemistry is directed by Academician G. Fodor. The scientific work of the department is concentrated on the stereochemistry of organic compounds (stereochemistry of nitrogenous compounds, tropine alkaloids, piperidine ring, chloramphenicol, etc.). An investigation on the hydrogenation of furan and processes of oxidizing -furaldehyde is being carried out. Studies of the configurations of carbohydrate derivatives are being carried out with the aid of stereospecific reactions, e.g. $\omega \rightarrow \alpha$ acyl migration, ring closure of 2-ureido and 3-ureido alcohols, formation of lactone salts for proving the configuration of tertiary amino alcohols. At present syntheses of optically active tertiary amines are being carried out; in particular, of 6-tropen-3-ols. In this connection a new method has been developed for the preparation of monoacyl derivatives of diols by the reduction of phenylurethans of hydroxy ketones and the thermolysis of the acylated diol monourethans.

In the Department of Pharmaceutical Chemistry (directed by Professor E. Vinkler) various organic sulfur compounds are being investigated, in particular the reactions of aromatic sulfonyl chlorides (reduction and condensation). The Department of General and Physical Chemistry is directed by Professor A. Kiss. The main lines of investigation are: the mechanism of light absorption, particularly by complex compounds; an electrochemical investigation of the initial stages of the corrosion of metals; and the kinetics of some reactions in solutions.

Much research is being carried out in the laboratories of the Veszprem Chemical University. This establishment corresponds to our institutes of chemistry and technology. The Department of General and Inorganic Chemistry is directed by E. Bodor. Investigations are being carried out on the chemistry of organometallic compounds, namely, metal carbonyl compounds, particularly mixed compounds (cobalt-mercury and others). The polarographic method is used for the determination of germanium and the study of the properties of organometallic compounds. The Department of Inorganic Technology is directed by Professor K. Polinszky, who is a specialist on mineral technology.

The Petroleum and Gas Research Institute (directed by Academician M. Freund), which is also in Veszprem, is carrying out investigations on the deparaffination of lubricating oil distillates by the urea method. Work is being developed also on the oxo synthesis, in which carbon monoxide and cobalt carbonyl are being used (J. Berty). A pilot-scale apparatus has been constructed for the catalytic preparation of acetic acid from methanol at high pressure with iodine as promoter and water as solvent.

Valuable chemical investigations are being carried out in Debrecen University (Professor Szarvas and others), the Pharmaceutical Chemistry Research Institute in Budapest (L. Vargha, J. Kollonitsch, and others), the laboratories of the Sopron Forestry Institute (J. Kiss), the Plant Protection Research Institute in Budapest (K. Szabo), the Synthetic Fibers Research Institute in Budapest (R. Bacskay), and other scientific establishments.

In conclusion we must refer to the exceptionally cordial, warm reception accorded the delegation of the Academy of Sciences of the USSR by the Hungarian Chemical Society and Hungarian scientists. The Hungarian chemists unanimously expressed their desire to strengthen their scientific relations with Soviet chemists and to become acquainted more closely with Soviet experience in science and to make more extensive use of it.

PHASE DIAGRAM OF THE TERNARY SYSTEM $CaO - BaO - SiO_2$

N. A Toropov, F. Ya. Galakhov, and I. A. Bondar

We have previously studied the solid solutions formed between calcium and barium orthosilicates in a binary orthosilicate system [1]. It was of great interest to investigate the crystallization of these solid solutions in a ternary system; it was necessary to determine the position of the region of separation into layers in the zone of the system rich in silica. Moreover, a study of the system $CaO - BaO - SiO_2$ should aid in the development of new formulations of high refractory ceramics and cements of high density.

Rankin and Wright [2] made a detailed study of the binary system $CaO - SiO_2$, in which they established the existence of four chemical compounds: $CaO \cdot SiO_2$, $3CaO \cdot 2SiO_2$, $2CaO \cdot SiO_2$ and $3CaO \cdot SiO_2$. The system $BaO - SiO_2$ was investigated by Eskola [3], and it was established that four compounds were formed in the system: $2BaO \cdot SiO_2$, $BaO \cdot SiO_2$, $2BaO \cdot 3SiO_2$ and $BaO \cdot 2SiO_2$, of which two – barium disilicate and dibarium trisilicate – formed a continuous series of solid solutions. For the ternary system $CaO-BaO-SiO_2$ only a few binary sections have been investigated. Thus, Eskola [3] investigated the section between calcium and barium metasilicates; he finds that a ternary compound $2CaO \cdot BaO \cdot 3SiO_2$ is formed and that this melts at 1320° into $CaO \cdot SiO_2$ and liquid.

Separation into layers in some binary and ternary systems was investigated by Greig [4], who determined the equilibrium temperature for a system of two liquids (glasses) and cristobalite in several binary systems. Olshansky [5] determined the critical layer-formation temperatures in the systems $CaO-SiO_2$ (2110°), $MgO-SiO_2$ (2200°), and $SrO-SiO_2$ (1900°).

EXPERIMENTAL

The samples were prepared from the following materials: 1) silica in the form of a fine powder prepared from rock crystal (99.90% SiO_2); 2) barium carbonate (98.80% $BaCO_3$); 3) calcium carbonate (99.88% $CaCO_3$). A detailed description of the method of preparing the samples and the furnaces used is given in the paper of Toropov, Galakhov, and Bondar [6].

Methods of Investigation

In the study of the phase equilibria of this system we used the quenching method. When the crystallization of a melt was very rapid and a glass could not be obtained, we had recourse to the method of growing large crystals. The sample was weighed in a microfurnace on a loop of molybdenum wire; all the changes occurring in it could be observed through an optical pyrometer provided with a lens giving a high magnification. The temperature was raised until melting was complete, and was then lowered slowly until crystallization began, this point being marked by the appearance of turbidity in the sample. The sample was kept at this temperature for 5-10 seconds and was then thrown from the hot zone of the furnace by means of a magnet. The crystals of the primary phase formed under such conditions differ from the crystals that separate during quenching. The temperature at which crystallization began was determined by reading the temperature at which either the disappearance of crystals or their appearance from the melt could be observed with the aid of the optical pyrometer. When the character of the crystallization was such that it was impossible to determine the temperature at which it began, a simple melting point determination was carried out. The pyrometer scale was calibrated by means of substances of known melting point (calcium aluminate $CaO \cdot Al_2O_3$, 1600°; corundum, 2050°). The establishment of the primary phase and the liquidus temperature was carried out as follows for samples of high silica content: a small fragment of the sample was heated in a graphite crucible in a microfurnace until a definite temperature was reached, at which it was kept for not longer than five minutes. Quenching was effected by throwing the

crucible containing the sample into some Wood's metal by means of a magnet. For samples having high CaO and BaO contents, and also for certain high-silica compositions, cooling was carried out in the furnace without special quenching. Test samples were investigated with the aid of the polarization microscope (immersion preparations and thin sections) and the metallographic microscope (end sections); in some cases x-ray analysis was carried out. The refractive indices of the glasses were determined by the immersion method.

Results of Investigation

Region of layer-separation. As our previous investigation [5] showed, in the binary system $CaO-SiO_2$ the region of layer-separation extends over the composition: 72.0-99.5% SiO_2, and according to our results it extends in the ternary system as far as 11% BaO. This region is demarcated on the diagram (Fig. 1) by a binodal curve

Fig. 1. Region of layer-separation, demarcated on the phase diagram of the system $CaO-BaO-SiO_2$ by a binodal curve (broken line).

(broken line). In the region of layer-separation, two glasses are formed. One glass is more acid (siliceous) and of higher viscosity, and it therefore remains transparent after quenching. The other glass is more basic and fluid, and it is difficult to quench it without the formation of fine crystals within it. x-Ray investigation showed that these fine crystals are grains of cristobalite. Under the microscope samples from the region of layer-separation appear as very small spheres of basic glass distributed through the acid glass. The smallest spheres of basic glass were quenched into transparent ones, but the larger spheres contained separations of cristobalite. In the photomicrographs shown in Fig. 2, a and b, it is possible to see the transparent segregations of basic glass and basic glass containing grains of cristobalite.

As is well known, when one solid and two liquid phases are formed in a binary system, the equilibrium will be invariant, i.e. both temperature and concentration must be constant for the existence of three phases in equilibrium. In this case – for a condensed system – in accordance with the Phase Rule, the number of degrees of freedom must be zero; the equilibrium of three phases will be represented by a horizontal straight line. For ternary systems, equilibrium between one solid and two liquid phases will be represented by a plane. This plane for the existence of three phases will not be horizontal, but will be inclined, owing to the fact that equilibrium in a ternary system is univariant. According to the Phase Rule, there is here one degree of freedom, i.e. the temperature can be changed without disturbing the equilibrium of the system.

We showed that in the system $CaO-BaO-SiO_2$ the plane for the existence of two liquids (glasses) and cristobalite has only a very slight inclination from the binary system $CaO-SiO_2$, in which the temperature for

Fig. 2. Photomicrographs showing the formation of two glasses (separation of a basic glass from an acidic glass): a) composition of sample 95% SiO_2, 2.5% BaO, 2.5% CaO; b) composition of sample 90% SiO_2, 5% BaO, 5% CaO. (Transmitted light; × 320)

Fig. 3. Space model of layer-separation region in the system CaO–BaO–SiO_2.

the equilibrium of three phases corresponds to 1698°, to the ternary system, in which for 11% BaO the temperature is 1690°. The position of the connode in the region of layer-separation was determined from the refractive indices of acid glasses quenched from 1710°, 1800°, 1900°. If for two different samples the refractive indices of the acid glasses are the same for the same temperature, then the figurative points of these samples are on the same connode; the same applies to the basic glass. Only the proportions of the acid and basic glasses will vary, and these will be related by the law of the lever. Table 1 gives the compositions of samples distributed on eight connodes and the refractive indices of the acid glasses.

In the region of layer-separation, the critical separation temperatures were determined, i.e. the temperatures above which a single glass is formed. The values of the critical separation temperatures for different compositions are given in Table 2.

On the basis of the results of our investigation, a schematic space model of the layer-separation region was constructed (Fig. 3), temperature (°C) being plotted along one axis, and chemical composition (% by weight) along the other two. The model has the form of a dome, at the base of which lies a plane for the coexistence of two liquids (glasses) and one crystalline phase, and the summit of which lies at the critical separation temperature for the binary system CaO–SiO_2 (K). The position of the point K' on the binodal curve was established by Alekseev's law [7]. The coordinates of this point correspond to 5% CaO, 11% BaO, and 84% SiO_2 and a temperature of 1690°.

It follows from Esin's work [8] that the reason for the formation of a layer-separation region lies in the differences in the energies of interaction of ions in silicate melts. This energy of interaction depends on the radius and charge of the metal cation and also on the electronic structures of the ions. If in the dissolution of MO in SiO_2 the interaction forces between the cation and O^{2-} are weaker than the interaction forces between Si^{4+} and O^{2-}, then all of the oxygen ions will move from MO to SiO_2 and separation into layers will not occur. This

Fig. 4. Photomicrographs showing a series of crystallizations for a composition lying in the solid-solution field close to the $3CaO \cdot 2SiO_2$ field: a) solid solution, 1390°; b) solid solution + $3CaO \cdot 2SiO_2$, 1385°; c) $3CaO \cdot 2SiO_2$, 1375°; d) $3CaO \cdot 2SiO_2 + CaO \cdot SiO_2$, 1360°. (Reflected light; x 420)

phenomenon can be observed when the charge of the cation is less than that of O^{2-} ($Li^+ - 0.78$ A; $Na^+ - 0.98$ A; $K^+ - 1.33$ A) and the radius is greater ($Pb^+ - 1.82$A). Separation into layers is again not observed in the silicates of beryllium ($Be^{2+} - 0.34$A), aluminum ($Al^{3+} - 0.57$A), and boron ($B^{3+} - 0.24$A) owing to the closeness of the interaction forces of these elements and silicon with respect to oxygen. In this case SiO_2 and MO can replace one another and form common groups with oxygen. When there is strong interaction between the cation and oxygen, as found in the silicates of Mg ($Mg^{2+} - 0.78$A), Fe($Fe^{2+} - 0.83$A), Zn($Zn^{2+} - 0.83$A), Mn($Mn^{2+} - 0.91$A), Co($Co^{2+} - 0.78$A), Ni($Ni^{2+} - 0.78$A), Ca($Ca^{2+} - 1.06$A), and Sr($Sr^{2+} - 1.27$A), only a few of the oxygen ions pass over to the SiO_2, the bulk of them surrounding the cation, forming cybotactic groups of different compositions (close to MO and SiO_2). The liquid then becomes microheterogeneous and separates into layers.

As indicated above, in the binary system $CaO - SiO_2$ the region of layer-formation extends within wide limits. Depending on the nature of the cation of a third component that may be introduced, this region may extend insignificantly or may extend further within fairly wide limits in the ternary system. Thus, "weak" alkali-metal cations, cations of high atomic radius (Pb), and also small multivalent cations (Be, Al, B) bring about an insignificant extension of the limits for layer-separation in the ternary system $MO - CaO - SiO_2$. A

Fig. 5. The positions of sections for the study of the solid-solution field in the ternary system CaO–BaO–SiO_2.
